—M. H., *Acklam Hall, Middlesbrough-on-Tees.*

GRUBS DESTROYING THE TURNIP CROP.

THE grubs which have devastated "acres upon acres of Turnips in East Kent" are the caterpillars of the *Agrotis segetum*, a moth which in the dry season of 1864 also committed great mischief on nearly all sorts of vegetables, and which the long drought during the present year has also developed to a fearful extent; the moths having been enabled to lay their eggs without interruption by wet in June last. The earth round the crowns of the plants should be carefully moved by hand, and the grubs, often several at one root, picked out and destroyed. They are now nearly full grown, and will soon bury themselves deeper in the earth to undergo their transformations. When the earth is moved by the plough in the spring children should be employed to pick up the chestnut-coloured shining chrysa-

birds, or they may be left to the rooks if there are plenty in the neighbourhood. Fowls will also eat the grubs greedily, but will not hunt for them.—I. O. W.

ISABELLA GRAY ROSE.

I HAVE a Rose called Isabella Gray; I have had it for ten years, but it has never flowered, but grows most luxuriantly. Can you tell me the reason, and give me the history of this Rose?—GADGIRTH, N.B.

[Isabella Gray was raised, I believe, in South Carolina, U.S., from the Cloth of Gold; and Maréchal Niel was raised from Isabella Gray by Pradel, jun. It is curious that the parent and grandchild should bloom so freely, and Isabella be so reluctant to do likewise. I have three trees of Isabella Gray 6 feet in advance of my vinery, and so luxuriant that "D., Deal," mistook them for six plants. They have bloomed tolerably freely this summer; and when the buds are hard they are still useful for bouquets. There is no doubt that all yellow Roses prefer hot walls to any other position. It is also true that some reluctant bloomers flower freely with shade to the south of them. William Bull is a glorious first-class Rose in this position, but as hard as a mortar ball when exposed to the sun.

I believe we puff up Roses and puff them out much too soon. A Rose miserable on one stock or in one position in the garden, may be glorious on another stock and in another position. I advise carefully taking up Isabella Gray, and trying a wall, first a south wall and afterwards an east wall. I further advise this variety being planted on the surface, earthing-up like a molehill, so as to allow the sun full action on the roots. In this case, in such a hot summer as the last, the plant should be mulched, and watered copiously twice a week. Under all circumstances it would be well to dig a deep hole under the site before planting, and to sink stones for free drainage. All Tea and Tea-scented Roses like high cultivation, deep drainage, intense heat, and copious waterings. I am not sure as to the raiser. Probably the name was given in honour of one of Asa Gray's family.—W. F. RADCLIFFE.]

NEW BOOK.

The Wild Garden: or our Groves and Shrubberies made Beautiful by Hardy Exotic Plants, with a Chapter on a Garden of British Wild Flowers. By W. ROBINSON, Author of "Alpine Flowers," &c. London: J. Murray.

MANY years ago a gentleman, an ardent lover of natural beauty, wandered through the New Forest, following the route pointed out by the best sketcher and analyst of landscapes, the Rev. William Gilpin, in his "Remarks on Forest Scenery." That volume was our friend's companion, and he saw so many illustrations of one passage in "Forest Scenery," that he resolved to accept it as a lesson and be its copyist. One illustration especially impressed him. On a tongue of high ground stood a weeping Birch, close to it were groups of *Osmunda regalis* Fern, among and above which were pyramids of Foxgloves laden with their pink bells; and the sloping sides, and, indeed, the whole surface, were clothed with the tender green Wood Sorrel, dotted here and there with tufts of low-growing Ferns.

The passage in "Forest Scenery" referred to is this:—

"The larger kinds of weeds, and wild flowers have their effect in filling up the smaller vacancies near the ground; and add to the richness of the whole. Among these, the Heath, and Broom, with their purple and yellow tints; the Foxglove with its pale red pendent bells; the wide-spreading Dock, and many of the Thistle tribe, are very beautiful. The hne of the Furze, too, is pleasant; but in bloom its luxuriant yellow is too powerful. Nothing can accompany it.

"But among all the minuter plants, Fern is the most picturesque. I do not mean where it is spread in quantities, but where it is sparingly and judiciously introduced. In itself it is beautiful. We admire the form of its leaf, its elegant mode of hanging, and its dark-brown polished stem. As an accompaniment, also, nothing is better suited to unite the higher plants with the ground; while its bright-green hue in summer, and its ochre tint in autumn, join each season with its correspondent tinge.

"Of all this undergrowth I know but one plant that is disagreeable, and that is the Bramble. We sometimes see it with effect scrawling along the fragments of a rock, or running among the rubbish of a ruin; and though it is even then a coarse appendage, I should not wish to remove it from landscape. But as a pendent plant it has no beauty. It does not hang carelessly, twisting round every support, like the Hop,

and others of the creeping tribe; but forms one stiff, nopliant curve. Nor has it any foliage to recommend it. In other pendent plants, the leaf is generally luxuriant, and hangs loosely in rich festoons; but in the suckers of a Bramble the leaf is harsh, shrivelled, and discoloured. In short, it is a plant, which should not, I think, presume in landscape farther than hath just been allowed: it has little beauty in itself, and harmonises as little with anything around it; and may be characterised among the most insignificant of vegetable reptiles."

Our friend did copy and illustrate that passage, using, however, for garnishing his shrubbery, not only our native Ferns and flowering plants, but hardy exotics, *Aconites*, *Hepaticas*, *Mezereons*, and others now too rarely found anywhere but in the gardens of old people who still wear poked bonnets and blue coats with gilt buttons.

What our friend did Mr. Robinson advocates—well advocates—in the volume before us. He does, however, much more, and does that well also. He gives descriptive classified lists of the plants suitable for ornamenting our shrubberies, and tells the soils and situations those plants prefer. "My object," says Mr. Robinson,

"Is to show how we may, without losing the better features of the mixed bedding or any other system, follow one infinitely superior to any now practised, yet supplementing both, and exhibiting more of the varied beauty of hardy flowers than the most ardent admirer of the old style of garden ever dreams of. We may do this by naturalising or making wild innumerable beautiful natives of many regions of the earth in our woods, wild and semi-wild places, rougher parts of pleasure grounds &c. and in unoccupied places in almost every kind of garden."

"My reasons for advocating this system, as I do, are as follows:—First, because hundreds of the finest hardy flowers will thrive much better in the places I recommend for them than ever they did in the old-fashioned border. Even comparatively small ones, like the Ivy-leaved Cyclamen, a beautiful plant that we rarely find in perfection in gardens, I have seen perfectly naturalised and spread all over the mossy surface of a thin wood. Secondly, because they will look infinitely better than ever they did in gardens, in consequence of fine-leaved plant, Fern, and flower, and climber, ornamental grass, and dwarf trailing shrub, mutually relieving each other in ways innumerable as delightful. Any one of a thousand combinations, which this book will suggest to the intelligent reader, will prove as far superior to any aspect of the old mixed border, or the ordinary type of modern flower garden, as is a lovely mountain valley to a country in which the eye can see but canals and hedges. Thirdly, because, arranged as I propose, no disagreeable effects result from decay. The raggedness of the old mixed border after the first flush of spring and early summer bloom had passed was intolerable, bundles of decayed stems tied to sticks making the place look like the parade-ground of a number of crossing-sweepers with their arms piled. When Lilies are sparsely dotted through masses of *Rhododendrons* as I recommend, their flowers are admired more than if they were in isolated showy masses; when they pass out of bloom they are unnoticed amidst the vegetation, and not eyesores, as when in rigid unrelieved tufts in borders, &c. In a wild or semi-wild state, the beauty of individual species will proclaim itself when at its height; and when passed out of bloom, they will be succeeded by other kinds, or lost among the numerous objects around. Fourthly, because it will enable us to grow hundreds of plants that have never yet obtained a place in our 'trim gardens,' nor ever will be admitted therein. I allude to the multitudes of plants which, not being so showy as those usually considered worthy of a place in gardens, are never seen there. The flowers of many of these are of the highest order of beauty, especially when seen in numbers. An isolated tuft of one of these, seen to a formal border, may not be considered worthy of a place at any time—in some wild glade, in a wood, associated with other subjects, its effects may be exquisite."

Mr. Robinson assigns other good reasons, but here we must close our notice. We recommend the book, for it will help to increase the beauty of all pleasure grounds, whether around a small villa or encircling a princely mansion.

WINTER-BLOOMING ORCHIDS.—No. 7.

COELOGYNE.

THIS is an Indian genus of great interest, which comprises two distinct sets of plants. Some authors separate them into two genera, *Coeologyne* and *Pleione*, whilst others consider the latter only a sub-genus. I consider them, however, well deserving of generic rank, and as such I shall treat of them here. The *Coeologynes* are all compact-growing plants, and readily become handsome specimens; they recommend themselves also on account of many species thriving well under cool treatment.

Coeologyne is a somewhat extensive genus, but I must here confine myself to the best of those which enliven our dull months. In order to produce good flowering plants, the majority of them should be potted, at the same time they must be well elevated above the rim of the pot, and the pots must be well drained. The soil should be good fibrous peat, a little sphagnum

moss, and sand; and in addition I have used, with advantage, a small portion of good leaf mould, but it must be good. During the growing season the species of *Celogyne luxuriante* in a plentiful supply of water both upon the foliage and at their roots; when growth is complete gradually withheld water, and expose them well to the influence of sun and light, in order to ripen their growth, whilst during winter a very small quantity of water will suffice.

C. CRISTATA.—This is, perhaps, one of the most elegant of winter-flowering Orchids, compact in its habit of growth, with dark green ovate pseudo-bulbs about 3 inches in length, bearing two linear-lanceolate, somewhat leathery, dark green leaves, with wavy edges. The flowers are produced in nodding racemes, four or five together, each flower being about 4 inches in diameter; sepals and petals oblong-lanceolate, the former narrower than the latter, all with undulated edges, and of the palest snow white; lip also white, concave, having five raised parallel lines along the centre, which are fringed or crested, and suffused with clear delicate yellow. This lovely plant lasts a considerable time in full beauty; it is extremely ornamental in the plant house, and it may be removed to the drawing-room without injury. It is also admirably adapted for adorning ladies' hair. Native of Sikkim, at 6-7000 feet elevation.

C. CORRUGATA is a much smaller plant than the preceding. The pseudo-bulbs are ovate and wrinkled; leaves in pairs, oblong, somewhat acuminate, membranous, and dark green. Racemes erect, bearing from three to six flowers; sepals and petals oblong-acute and pure white; lip smaller, white, yellow inside, and streaked with orange, having three raised parallel lines on the disc. A rather uncommon but very elegant cool-house species. Native of the Madras Hills.

C. FLACCIDA.—This species produces drooping spikes of flowers, which are strongly but not very pleasantly scented. Pseudo-bulbs oblong and ribbed; leaves long, somewhat lanceolate, petiolate, dark green, and leathery. Racemes zigzag, drooping, and many-flowered; sepals and petals white; lip white with a yellow centre, recurved at the point, and toothed at the base, where it is streaked with crimson. The plant will succeed either in a pot or upon a block; in the latter manner its drooping racemes are displayed to the greatest advantage. It blooms during January and February, and during the growing season requires more heat than the kinds previously named. Native of Nepal.

C. SPECIOSA.—This plant is more properly an autumn flowerer, but as at this season flowers are scarce, it well deserves a place in every amateur's collection. The pseudo-bulbs are ovate-oblong in shape, and bear a single oblong-lanceolate dark green leaf. The flowers are about 3 inches in diameter, and usually produced in pairs; sepals and petals reflexed, dull brown; lip large, crested in the centre, of the same colour as the petals, with the front portion white. Native of Java.

C. ODORATISSIMA.—An elegant but small-flowered kind. The small size of the flowers is no doubt the reason of its being so little grown, but being white and sweet-scented they are very acceptable for cutting during March and April. The whole plant seldom exceeds 6 inches in height, both pseudo-bulbs and leaves. The flower-spike, which is produced simultaneously with the young growth, is drooping, and bears about three flowers, which are all white except the centre of the lip, which is yellow. It is a cool-house plant from the mountains of Madras.

C. GARDNERIANA.—A plant far less grown than it deserves to be. The pseudo-bulbs are somewhat flask-shaped, tapering upwards from the base; leaves from 10 to 18 inches long, and about 3 in breadth, lanceolate, acuminate, petiolate, and bright green; the racemes are slightly drooping, bearing from six to eight large flowers, which are pure white, saving the centre of the lip, where it is stained with lemon colour. Native of East Indies, in Nepal, and Khasia.

C. OCELLATA.—This species should be grown upon a block of wood, where it will form an elegant specimen, and produce its chaste flowers during February and March. The pseudo-bulbs are shining, ovate, and angular; leaves lanceolate, narrow at the base, and about 10 inches long. Flower-spike 6 inches or so in length; sepals and petals white; lip of the same colour except at the base of the middle lobe, where there is a yellow spot, and the lateral ones are also stained with deep yellow. Native of Khasia and Sylhet.

C. FUSCESCENS is, perhaps, the least desirable species, especially if the collection is small, or the space limited. However, where the space for two or three pots more or less is not of vital importance, this plant should find a place. The pseudo-bulbs are about 4 inches high, round, and rather thin, bearing

oblong acute leaves 9 inches in length, and nearly 3 broad; raceme nodding, and bearing about five good-sized brown and green flowers. It succeeds in a cool house. Native of Nepal.—*EXERTO CREDE*.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

CEREUS FULGIDUS (Brilliant-flowered Cereus). *Nat. ord.*, Cactaceae. *Linnaeus*, Icosandria Monogynia.—The history of this flower is unknown. It has bloomed annually at Kew for many years. Flowers scarlet, opening early in an evening, and remaining expanded until the following noon.—(*Bot. Mag.*, t. 5856.)

BRODIAEA COCCINEA (Crimson-flowered Brodiaea). *Nat. ord.*, Liliaceae. *Linnaeus*, Hexandria Monogynia.—It is a brilliant-flowered bulbous plant, native of California, blooming in May and June. Flowers crimson, tipped with yellow and green.—(*Ibid.*, t. 5857.)

ONCIDIUM CRYPTOCOMIS (Long-sepalled Oncidium). *Nat. ord.*, Orchidaceae. *Linnaeus*, Gynandria Monandria.—Native of Peru. Flowers brown, edged with yellow.—(*Ibid.*, t. 5858.)

TABERNEMONTANA BARBERI (Mr. Barber's *Tabernemontana*). *Nat. ord.*, Apocynaceae. *Linnaeus*, Pentandria Monogynia.—Native of Old Calabar and other districts of the tropical west coast of Africa. Glabrous shrub. Flowers white.—(*Ibid.*, t. 5859.)

SALVIA INTERRUPTA (Ash-leaved Sage). *Nat. ord.*, Labiatae. *Linnaeus*, Didynamia Gymnospermia.—"A tall hardy herbaceous plant, with a woolly suffrutescent stem, belonging to the same set of Sages with *S. officinalis*, and many other handsome species that are common ornaments of continental gardens, but are all but wholly unknown in our own. It was, according to the 'Hortus Kewensis,' formerly cultivated in the Royal Gardens under the name of the Ash-leaved Sage, having been originally introduced from Morocco into the Cambridge Botanic Garden, 1798. It has, however, long since disappeared from cultivation, and so remained till three years ago, when it was reintroduced from Tangiers by G. Maw, Esq., of Benthall Hall, during a botanical expedition into North Africa, from whence he sent living plants to the Royal Gardens that flowered in May of last year. From its habit of flowering through several successive months, it is well worthy of cultivation in the open border."—(*Ibid.*, t. 5860.)

PRIMULA CORTUSOIDES AND ITS VARIETIES.—"In the large Japanese varieties of *Primula cortusoides*, so much superior to the ordinary form as to appear quite distinct, we have acquired some of the choicest and most beautiful materials for ornamenting the hardy flower garden. The public are indebted to the late Mr. John Gould Veitch for the introduction, and to the Messrs. Veitch & Sons for the distribution of these charming hardy plants. *Amæna* is of the richest magenta, with white centre, and has notched but otherwise entire segments; *striata*, a pretty lilac, which has the margin of the flowers toothed, and the colour prettily striated; and *grandiflora*, remarkable for its drooping concave or cup-shaped form, and for having the inside almost pure white, while the outer surface is of a rosy purple hue. The variety *striata* has been sometimes called *lilacina*, a name which is now cancelled. Besides these, there are *alba*, with pure white blossoms, and *albida*, with blossoms of a greyish white, and of the same drooping type as *grandiflora*. These *Primulas*, grown in pots, form excellent decorative plants for cool houses in spring."—(*Florist and Pomologist*, 3rd s., iii., 193.)

WEEDS.

(Continued from page 128.)

THE removal of weeds being conducive to the value of a crop, their extirpation must be an important means of keeping up the fertility of the soil, and securing an increased produce. It is impossible to have a good crop if it is weedy, as the soil's fertility is wasted on the weeds instead of being devoted to the crop.

Apart from the deficiency in produce, and the waste of the soil's fertility, the evil effect of weeds presents itself in many forms of disease to which vegetable life is subject when deprived of light and air. To allow weeds to grow as well as the crop is simply to cause the production of drawn, weak plants, incapable of supporting themselves against wind and rain; whilst in times of drought weeds are a direct cause of the crop lagging behind, the ears of corn not filling, and the roots not swelling. Half and more of the failures and deficiencies of the agriculturist are a result of the little care taken, as a rule,

to keep down weeds. He looks upon them as altogether contemptible. What is the use of imposing penalties for the adulteration of seeds when we see the agriculturist so heedless of the growth of weeds with his crops, and the ripening of their seeds with his grain? It is not the weed seeds sown with the seed of his crops that the farmer has to fear, but those he harvests with every crop, and which, being rejected by his animals, find their way to the fields again with the manure.

Some very nice calculations have been made as to the increase some weeds are capable of by their seeds in the course of a year; but can anyone tell the decrease in the yield of Wheat, Barley, Oats, and other crops caused by the unrestrained growth of weeds? Some will, no doubt, jump to the conclusion that the deficiency is of no practical moment. Presuming that to be case, and I cannot for a moment admit it, how does it happen that the best and most profitable farming is that which is the cleanest? Or, why should gardens afford more than double the produce of the best land of the agriculturist? Is it because the system of culture is different the ground more deeply dug, more manure applied? Or can it be that the weeds as they appear are cut down, the whole resources of the soil reserved for the plants it is cropped with? "Oh, but gardens do not pay!" The fact is they do pay, and the ground is worth twice, often four times as much rent as the same land is let for to the farmer. I have no doubt but that the yearly produce of every acre of land in Britain would be doubled were the ground kept as clear of weeds as it is by the gardener. What is the practical value of draining, of deep cultivation, and manuring, if the resources of the soil be expended in a growth of weeds, in many cases little inferior to that of the crop? Where good crops are reared, there are good cultivation and freedom from weeds.

I have digressed, and could digress very wide of my purpose, to endeavour to show that the land of this country is not agriculturally so productive as it is horticulturally, and that if it is to be rendered more productive, such a result will be attained by a system like that of the gardener—by deep cultivation, free exposure to the air, and allowing nothing to grow upon it except those cultivated plants essential to the health and comfort of man.

No one knows better than the gardener and amateur what are the injurious results of weeds permitted to grow with plants or crops of any kind. It is well known that fall good crops are not had along with a profusion of the plants which the ground naturally produces. Whatever is sown or planted does not attain perfection without an array of weeds, each seeking the continuation of its kind; therefore to secure a good crop, whatever it may consist of, the ground must not be occupied by anything else.

For the successful cultivation of every plant it is essential, first that the soil be open, affording free access of water, air, and manurial agents to the roots of plants; secondly, that the plants have air and light. To secure the former result the soil must be frequently stirred, and the more it is stirred both as regards depth and frequency the more vigorous are the plants. The deeper the cultivation the less is the danger from drought, for the roots penetrate further, and the inert soil, exposed to air, slowly and surely yields to its influence, whilst a loose surface admits the rain and dew, and allows a freer admission of air and solar heat than a hard close surface. This is well exemplified by land of which one part is surface-dug and another part trenched. There is no comparison between the crops. The first suffers from drought, the growth is weak, and the produce correspondingly small; but the latter withstands drought well, the rains penetrate more deeply and more regularly, and the plants are more vigorous and attain a higher degree of perfection. Whilst in the one case there is a weedy crop, in the other it is remarkably clean.

When plants are sown and allowed to attain maturity close together, being deprived of light and air, they have a weak growth. The support taken from the soil is divided between many plants, and light and air having diminished access to the plants, the nutriment is imperfectly elaborated; hence they are drawn up weakly, and the produce is poor. On the other hand, if plants have space for their full development, and are exposed to light and air, they are strong and attain a high degree of perfection, the produce being greater and of better quality. Every plant left in the ground beyond what can have proper support and due exposure to light and air is a robber—in fact a weed. If we plant Cabbages at 1 foot apart we know that the produce is not equal in quantity to what it is with half the number of plants at 2 feet apart; therefore we may, by

having twice as many plants on the ground as it can support or can have light and air, obtain a result no better than were we to allow weeds to grow with what we sow or plant. Weeds have the same influence on our crops as allowing too many plants to grow in a given space—two, three, or more where one only should be. They waste the soil's fertility, deprive the cultivated plant of part of its sources of support, and keep from it the essential agents for elaborating the sap—light and air. There is this difference, however, that whilst a thick seeding or planting will give produce less in quantity and inferior in quality, weeds allowed to grow with plants at a proper distance, whilst they cause a less and inferior yield of the cultivated crop, like thick sowing or planting, cause nothing but vexation present and future.

The object of all cultivation is to secure crops of plants useful to man. All soils have a greater adaptability for the growth of some plants rather than others, hence increased facilities are afforded for the cultivation of a greater variety of plants than were all soils alike in their constituents. Naturally we have plants suited to every soil, situation, and climate, whether these plants are in a natural or in a cultivated state. All vegetation improves with cultivation, though some have ideas of there being such a thing as degeneration, whereas everything in nature is advancing towards perfection, cultivation causing nature to show itself in new and improved forms. To make the ground suitable for the plants affording support and enjoyment to man it must be improved, the original vegetation got rid of, or to such an extent as to be rendered subordinate to that intended to supplant it, and he cannot fit the soil for the reception of a cultivated plant without removing the original vegetation; the means necessary to secure a cultivated plant's free growth and maturity being the readiest means of freeing the land of the obnoxious weeds. Indeed, the whole system of culture is based on the extermination of useless plants, and rearing in their place those which are useful. Still we cannot cultivate the ground without first clearing it of the original vegetation; nor, in the second place, can we have a cultivated crop without weeds, for however well the ground may be prepared plants will come up which we must remove, or if we allow them to remain we must submit to a decrease in the value of the crop. If we turn a bog into a dry place we do not find the land become barren; the bog or marsh plants disappear, and are replaced by vegetation of a very different class, and in turning up a piece of the original wild, completely destroying the present vegetation, the soil gives us vegetation in another form in its place. No art of man is sufficient to prevent vegetation appearing without rendering the soil wholly unsuitable for the growth of plants.

Now, the best means of destroying weeds is preparing the ground for the plants we wish to cultivate. The first, and, perhaps, the most important part of cultivation is draining. "And what has this to do with the destruction of weeds? If it improve the ground for a cultivated plant, the weeds must grow all the more rank as a consequence!" We must not lose sight of all our labour being expended for a cultivated plant, one that from cultivation is more tender, and less capable of enduring hardships than one in its wild state. A plant is rendered less hardy by cultivation; we require for its growth more warmth, which is afforded by draining, which removes all the water that would otherwise lodge in the subsoil, and leaving none but what the soil is capable of returning. In this way the soil is rendered warmer, for the rains, which are charged with ammonia, pass directly to the roots, and containing less water the soil is more quickly warmed by the sun. It absorbs heat and moisture better, and air has access to it; besides, water is slower in heating than any kind of soil, consequently to have an undue amount of water in the soil is to reduce the soil's heat-absorbing power, and consequently warmth. Though for cultivated plants it is essential to free the soil of all stagnant water, and to afford a free passage for rain through the soil, doing so is certain destruction to some native plants, or what are in many places noxious weeds, and without draining it is extremely difficult to make them secondary to a cultivated crop. It would be useless to seek the destruction of the Horsetails or Equisetums by any other process of culture than draining. Cutting off the tops weakens them to a considerable extent, but they root so deeply that any injury to the tops is soon repaired, and there are times when their tops must make headway, and the roots are consequently strengthened; but if we drain the soil, remove the water from the subsoil, their growth annually becomes less, and in time they disappear. For the destruction of the Horsetails there is no means but draining.

Not only is it necessary for destroying those which grow in soils that are thoroughly saturated, but also for killing those growing where there are no signs of moisture on the surface. The Marsh Horsetails (*Equisetum palustre*, and *E. limosum*), and the Great River Horsetail (*E. fluviatile*), must for their destruction have the water in the soil drained off, and equally so the Wood Horsetail (*E. sylvaticum*), and Corn Horsetail (*E. arvense*). The latter, especially, though often abundant on light shifting sands, is doomed to destruction when the soil is efficiently drained.

Again, in low wet soils there is often a preponderance of semi-aquatic Grasses and allied plants, that in a great measure yield to draining. The *Carex* family, the Rushes (*Juncus*), and many others, owe their existence to moisture in the soil, moisture more than the soil would retain had it an outlet by the sub-soil. Drain the ground where those are, and they disappear.

It would be useless enumerating all the plants of which draining assists in freeing the soil, but I must not pass over *Thistles*, *Docks*, and several others with root stems that penetrate to a great depth, and need for their free, vigorous growth, moisture in the soil, and that to a greater extent than is beneficial to cultivated plants.

The casual observer will have noticed that the natural vegetation occurs in patches of one species of plant in a place, or if there are several, one of them is more vigorous than the others. Now, if we were to drain the ground that grows a great variety of plants naturally, it does not follow that we should destroy every plant, but on the contrary, whilst we destroyed some, others would be invigorated. Fortunately there is no cultivated plant, in this country at least, that is not improved by being grown in well-drained ground; such ground improves every crop in quantity and quality, and entirely changes the character of the natural vegetation. Indeed, so beneficial is draining to us in cultivating the soil, that no one ought to neglect it. It is but seldom that the agriculturist neglects it; but many gardens, and especially small gardens, are not drained at all, or very inefficiently, the weeds grow remarkably strong, and many plants are lost every year from the wetness of the soil. Fruit trees are barren, their growth sappy, or the branches moss-covered. The cause is attributed to bad soil into which the roots have struck, whereas it is all due to the water not having a means of escaping from the subsoil. Measures are taken to keep the roots from descending into the cold, wet subsoil, but no thought is given to the fact that they are wholly unnecessary, the sub-soil were rendered dry by efficient drainage.

Drains to be of service should be deep. The rain must enter by the surface, pass through the soil as if it were a sieve, and be freely carried off. The water should be attracted, as it is by drains, from the surface to the roots, and not allowed to remain there and render the soil a wet, cold, inert mass. Experience points to 4 feet as the most suitable depth for drains. At that depth they are beyond the reach of any cultivated plant.—G. ABBEY.

(To be continued.)

INSECTS INJURIOUS TO THE PEAR TREE.

No. 5.

NARROW-WINGED RED BAR MOTH.

TORTRIX ANGSTIORANA, *DITULA ANGSTIORANA*, *PERDISCA ANGSTIORANA*.

IN AN early volume we warned all cultivators of wall fruit, as soon as they observed in May one of the leaves rolled up, to destroy the little caterpillar within the roll, and to watch for others, because the eggs of the moth from which that caterpillar came continue to hatch for several weeks. That moth is the Narrow-winged Red Bar. These caterpillars appear during May and June; they are about half an inch long, are pale yellowish green, and with the head brownish yellow. A few bristles are scattered over the body. It is a very active caterpillar, wriggling about in most varied contortions when disturbed, crawling with equal facility backwards and forwards, and letting itself down by a single thread from its mouth. It passes into the state of a brown shining chrysalis, rolled up in the same leaves, and from this the moth comes forth in July. The moth is very small, not longer than the

line below our drawing of the insect magnified. The fore wings are reddish brown, in bands of various degrees of darkness. The hind wings are dusky. It deposits its eggs, probably, upon the branches, where they remain all the winter. The caterpillars are most frequently found upon the Apricot, but it also infests the leaves of Pear trees.

SUMMER DROUGHT.

WHEN autumn rains are falling heavily, or spring's late showers appear unwilling to cease, we think not of the summer drought, or its moisture-consuming power; of the dry warm atmosphere which comes to us as though it had passed over burning plains, and which day and night surrounds everything. Yet all vegetation is hastened, or retarded, or suffers from its too long continuance. The summer drought changes all too rapidly the outward aspect of nature; beneath its influence the young growth loses its soft tender green, and assumes, as if by the touch of some fatal spell, the grey matured look of autumn—brown leaves, sap-dried before their time, mingle with summer's brilliant colours; fruits ripen ere they have half attained their size; and Flora, living too fast and working too hard, brings the end too soon. The Rose-bud withers as it opens, and the forced seed-vessels ripen and push away the beautiful petals before they have half enjoyed their blooming season; and the green grass is robbed of its verdure and becomes dust-coloured like the dry soil which is moved over it by every breath of wind. Stunted growth or cessation of growth is everywhere to be met with, for little of real growth can summer's heat accomplish apart from her twin helper moisture. How we tire of the long bright sunny days, and sultry cloudless nights! How man, and beast, and bird, and tree, and flower sicken beneath the scorching heat! Faded and weedy grows all the land; the water sheds are dry in the hills, and silent all the brooks in the valleys, and not a drop of moisture lingers in the *Calceolaria* bags, and wild flowers are not, and poor and withered are the numberless hosts of leaves that crowd the Oak tree. The sheep climb the mountains, or spread over the wolds, and seek in vain the moist sweet grass; and with an angry scream the rooks fly over the desert-like pasture fields; and the wild birds of the hills and woods forget their fears and freely slake their thirst with the home birds.

How we suffer from the summer's drought, and how anxiously we look for a change! We watch the sky, the clouds, and the winds; we look out in the early morning and grieve that the rain has not come, and in the eventide and hope it will; and in the dark hours of the night, when the breeze softly stirs the forest trees, our thoughts are of rain. Long-believed-in signs of a coming change visit us, and thus keep hope alive within our hearts; but even the weather prophets fail to read them aright. Soft, feathery, white clouds adorn the blue sky, tenderly veiling its brightness—"mare's tails" and "mackerel skies," enough with their foreboding to dispirit one on the eve of an excursion; but the clouds melt away and leave only an intenser blue, a heat more consuming in its power. Clouds rise in the east and in the west, they travel with the wind and against it, they meet in angry contest, but a few muttered thunderings and they part and go their separate ways in peace, the dispute settled, and to our loss no rain-tears fall. Threatening winds drive right into the "Noah's ark," boldly painted on a sea of blue, and we point in rapture to the unfailling sign, sure that the deluge will come; but the wind lulls, the ark goes on in safety, and the rain descends not. Nearer and nearer to our vision comes the distant landscape—woods, and fields, and cottage homes, and homes of prayer, all clearly revealed to us in the soft evening light; and we take heart of hope again, for all signs of change cannot surely fail. Yet day after day comes and goes the same; only drier and more irritating becomes the atmosphere, more parched and desolate the land, more autumn-like the summer foliage. The sun rises in glory, and travels in undiminished brightness through the blue immensity, and sets among vapour-clouds of gorgeous colouring, that turn each wayside weed, and blade of grass, and giant tree to burnished gold; but a grey morning follows the yellow sunset, and our momentary hopes are gone.

Then we look nearer home for signs of approaching change of weather that may be trusted in, and we take comfort, nay, almost pleasure, out of suffering, and fail to sympathise fully with the rheumatic pains of the long-ago injured limb, in the certainty there is damp in the air, rain bringing relief at last. All day the sun shines, all night the stars; but in the first

hours of the morning a thick heavy cloud passes low over the country and leaves it bathed in generous dew; nothing living and striving to grow is missed or forgotten, and when the sun comes forth he finds everything sparkling with joy, our pains of the body suddenly depart, but they leave a pain that will not go—a long-unanswered wish.

We become sceptical of signs, though the troubled wind goes sighing through every hole and cranny and unfastened window, and moans away into the far distance. And even our household gods break their accustomed silence, and startle us with strange noises, and stairs creak all night through, as though burglars with shoeless feet were ascending and descending; and veteran spiders come forth from their secret nooks to catch the first breath of moisture, and flies with their impatient visits torment the weary worker, and the pea fowl from the neighbouring garden lifts his discordant voice in louder and still louder notes, and deeper down go the worms in their wondrous search for the necessities of life; and the

swallows fly hither and thither, and hold long converse over the abbey ruins, and we know they are meditating a journey to more genial climates. Cold blows the wind from the north as though in pity; it beats hard upon the trees with a noise as of waves beating upon a rocky shore. The rain comes not, and through the same dusty lanes as the mower led his scanty crop goes the reaper with his golden harvest—a harvest that in the olden times was stored away for winter use, now pressed into the service of summer to supply her needs, to lessen the sufferings of the long summer drought.

At last the change comes, the welcome rain falls, slow at first but sure and certain, touching everything as with a hand of blessing, finding its hidden way among the hills, and giving a voice of gladness to every running brook, a sense of renewed life to every thirsty plant; the poor brown moss comes back to greenness, and every node of grass begins its work of growth anew, and surely all our hearts are filled with thankfulness.—MARD.

GARDENING IN THE LONDON PARKS.—No. 3.
THE CRYSTAL PALACE.

THE elevated position of the Crystal Palace, and the gentle manner in which the grounds slope away from it, tend to impart an additional dignity even to its gigantic proportions; this, and the scenery which it commands, proclaim the hand of a master in the selection of its site.

In a survey of the Palace and its surroundings one cannot fail to be struck by the peculiar tone, which this huge mass of glass and iron imparts to the whole scene. All who read these notes, if they have never seen the Palace, should remember that it is this peculiarity that enables the gardener to form

combinations of such striking colours in the flower beds as would be hardly adapted for small gardens, and which must be followed with the greatest caution, for the bold style of colouring which may be used here with safety, is hardly suited to the quiet repose of the small lawn or shrubbery. Not that I would wish to convey an impression that there are no beds at this place the planting of which may not be safely followed, for many of the circular beds on the rosery slopes are gems of refined beauty, which are quite certain to be appreciated in almost any position.

| <p>1. Verbena Purple King.
2, 2. Two rows of a Silver-edged Variegated Pelargonium like Perfection or Bijou.</p> | <p>3, 3. Two rows of pink Pelargonium Christiee.
4, 4. Coleus Verschaffelti.
5. Diamonds of Centaurea candidissima.</p> | <p>6, 6. Two rows Pelargonium Crystal Palace Gem.
7. Pelargonium Stella.</p> |
|--|---|--|

The flower beds at the Crystal Palace may be divided into two distinct groups; these are the rosery slopes, and the terrace. Taking the rosery group first, we have a bold mass of colour in the sloping border, which closely encircles the rosery itself. As the arrangement is somewhat complicated, I give the above sketch of the border in order to convey a just impression of its character.

The Coleus was very beautiful; nothing could be more satisfactory than its even compact growth, and the deep rich hue of its foliage. The effect of the entire border, fine as it undoubtedly was, would, I think, have been more pleasing had the flowers been kept picked off the yellow and white variegated Pelargoniums, and this I would insist upon more especially in the case of Perfection, for, situated as it was here between deep purple and bright pink, its white variegation seen pure and simple, as it ought always to be, would have produced an effect both chaste and refined in the highest degree. The dark green foliage of the Ivy and other climbing plants trained over the ironwork behind this border formed an excellent background. The bold style of its colours and its elevated position rendered it a conspicuous object, glimpses of which are visible from all parts of the grounds.

On the lawn sloping downwards from this border were a number of beds, most of which were of a circular form, and about 10 feet in diameter. Many of them were well arranged,

and all were sufficiently quiet in tone to be quite subordinate to the grand border. Of these the best was one having an edging of Pelargonium Flower of Spring surrounding a fine mass of a large-flowered purple Petunia. There were no names to the plants in any of the beds, which was to be regretted, as it robs them of much of their interest. In another bed was a mass of Centaurea candidissima, surrounded by a ring of Coleus Verschaffelti, with a broad edging of Golden Pyrethrum; this was very fine. The Golden Feather Pyrethrum has been remarkably healthy and well-coloured this season in all the gardens in which I have met with it.

Another circle was very attractive; in it Gazania splendens was edged with Echeveria secunda glauca. Another consisted of an equally fine mass of Coleus Verschaffelti, surrounded by a broad band of Centaurea candidissima, with an edging of Lobelia Paxtoniana. The great proportion of white in the flowers of this Lobelia renders it altogether unsuitable for planting next the Centaurea; L. speciosa, or some other deep blue variety, should have been used. A pair of these circles had fine rings of Iresine Herbstii, which has succeeded well in most gardens this season. Another bed, containing a mixture of the pretty Pelargonium Lady Plymouth and Verbena Purple King, was very good; so, too, was a mixture of Verbena venosa and Cineraria maritima. Another striking bed had a broad edging of Golden Pyrethrum surrounding alternate rings

of itself and a very compact-growing blue Lobelia. A novel effect was produced by surrounding a mass of orange and scarlet *Tropæolum* with an edging of *Nierembergia gracilis*; and a very neat and attractive bed contained white, orange, and pink Lantanas. These pretty Lantanas are alike useful in pots and beds, and, although somewhat old fashioned, yet when well managed they bear favourable comparison with all other bedding plants. A few mixed beds of Verbenas were very poor indeed, nor did it appear at all difficult to understand why they were so, for it was evident at a glance that they were planted in the ordinary garden soil, and hence their ragged and starved appearance. This was to be regretted, for, after all, the successful culture of Verbenas is a very simple matter. With a deep, cool, light, rich soil, and healthy plants at the time of planting, there need be no more failures with Verbenas than with Pelargoniums. The only advantage which the latter really possesses is that it will, under favourable circumstances, continue somewhat longer in full beauty than the former. We have only to afford the Verbena a sufficient quantity of that rich, cool soil, in which its roots love to spread, to produce beds of the most exquisite loveliness, and certainly far more attractive and interesting than those of almost any other denizen of the flower garden.

The great utility and beauty of circular flower beds is here fully demonstrated, and while there were several beds the colours of which were tame and their arrangement faulty, yet the majority of them were good in every respect and highly satisfactory.

In the hollow at the foot of the rosey slopes, on the side facing the water temples, a triangular space is enclosed or bounded by three walks, each of which runs parallel with one side of the triangle, which is of turf, having a fine *Wellingtonia* in its centre, and with three small triangular beds, one at each angle of the triangle. Each of these beds contained a mass of a light orange scarlet Pelargonium, with an edging of *Pelargonium Manglesii*, which filled the beds well; but the result would have been very much better had a deep crimson shade of colour been used in place of the orange scarlet, for then a rich and dignified effect would have been obtained; the deep colours blended together would have imparted just that air of importance which the group required to be satisfactory.

Proceeding from this part of the grounds to the terrace, I noticed in full flower some fine bold masses of Hollyhock, which struck me as being one of the best of plants to introduce in that way in such extensive grounds.

The beds on the terrace form no regular design, but are arranged in a single row round the principal plots of turf, each of which has a fountain in the centre, on the margin of which a few vases are placed. The chief display on the terrace was that of the two central groups, one on each side of the broad walk which leads from the Palace across the centre of the terrace down the various flights of steps. The form of each of the central spaces of turf will be easily understood if I compare it to the quarter of a huge oval, with the longest side facing the front of the terrace. The line of beds here consists of alternate circles and parallelograms, the formality of which is broken up by specimen standard shrubs, which spring from the centre of each of the circular beds. The flowers in these consisted of an outer row of Golden Pyrethrum, inside which were two rows of *Colerus Verschaffelti*, with a central mass of Pelargonium Provost. In every alternate circle Pelargonium Flower of the Day took the place of the Pyrethrum. The long beds had a broad band of Pelargonium Stella along the centre, with yellow *Calceolaria* on each side, and with a row of Verbena Purple King round the outside of the beds. The flowers and trusses of the *Calceolarias* were alike small. This long line of bright colours, softened somewhat by the mass of Provost, had a very bold effect, and the proximity of the "pale-hued Palace," deprived it of all its harshness, and even added to its beauty.

The line of beds running parallel to the walk along the other sides of these central plots of turf is peculiar; it consists of circular beds containing an *Araucaria imbricata* in the centre, alternating with very large empty vases, with high pedestals standing on turf, and surrounded by a broad ring having a wide band of either pink or scarlet Pelargoniums along the centre, with a margin of Pelargonium Flower of the Day on each side. These rings had a very good effect; but the circular beds containing the *Araucarias* appeared perfectly ridiculous, owing to the absurdly narrow row of *Cerastium tomentosum* enclosing a broad ring of blue Lobelia.

A line of beds by the side of the walk nearest the Palace, consisting of parallelograms broken occasionally by vases or

statuary, was very good. Of these beds one containing a mass of a very dwarf orange scarlet *Tropæolum*, bordered with an equally dwarf blue Lobelia, was very good; another had a splendid mass of Pelargonium Waltham Seedling. This fine variety has been very brilliant all through the past hot season. In others of these beds equally fine, Pelargoniums Amy Hogg and Provost, and a fine large-flowered purplish crimson *Petunia*, were noteworthy. All these beds had a uniform edging of blue Lobelia. The vases, which were of large and handsome proportions, contained a pleasing mixture of plants, the growth of which was very uniform. These vases, and beds were among the most effective of any that came under my notice, and this was undoubtedly owing to the broad rich masses of colour which the beds contained, for had there been much subdivision of colour here the effect would not have been nearly so telling.

The beds in the other compartments of the terrace contained nothing worthy of note; and I may very justly conclude this paper by observing, that while there is much in the arrangement of the flowers here to which the greatest praise must be accorded, yet there is also very much of the colouring which is faulty and insipid; it may be that there was a lack of better materials at the planting season. Knowing nothing of the resources of the Superintendent, I cannot say how this may be; but I may say that a season trying even as the past hot summer, can form no excuse for the tame appearance presented by many of the minor flower beds in these grounds.—EDWARD LUCKNURST, *Egerton House Gardens, Kent.*

THE FLOWER SERMON.

COLLINSON, in his "History of Somersetshire" speaking of Yatton, says, that "John Lane of this parish left half an acre of ground to the poor for ever, reserving a quantity of grass for strewing the church on Whit-Sunday."

For many years past a sermon upon flowers has been preached in Shoreditch annually on Whit-Tuesday; an old florist, Thomas Fairchild, enamoured of his floral charges, having bequeathed a certain sum of money, in trust to the Royal Society, "for the providing of a clergyman to deliver that sermon." This had been familiar to us, not only as a legend but as a reality, from our childhood's days, for our father had often been invited to preach it; and we, a large party of boys and girls about the tea-table, had been in the habit, for days before, of hazarding many a guess, or even bolder suggestion, as to what the text would or should be. "Consider the Lilies," was a favourite one, being very apposite. But "Much too commonplace, my love," would be the reply to that. "Rose of Sharon" came next; but naturally all these, patent to the minds of everyone, had year by year been used up, and we had to confess, when told, perhaps, that it would be such a one as "He giveth them their meat in due season," and that the discourse would turn upon corn, that it sounded much more "uncommon," and that there would be a great deal to say about it.

Shoreditch was a very long way off, and an out-of-the-way place to take young folks to. We did not attend these annual services, nor in fact were they much frequented by any. Perhaps not more than a dozen persons heard the carefully thought-out sermon, or profited by the lessons which the good old gardener, so long since dead, would have had them taught concerning the beauty and charm of God's creatures.

Knowing all this, which by-the-by, not one in ten thousand Londoners does know, we were taken by surprise when, about a week before Whit-Sunday last, an announcement appeared in the public papers to the effect that "The Flower Sermon, usually preached at St. James's, Aldgate, would this year be preached at the Church of St. Katharine Cree, Leadenhall Street, on Whit-Tuesday evening, by the Rev. W. M. Whittemore, D.D., that the service would be choral, members of St. Paul's Cathedral special service choir attending, that the church would be crowded, and that it was the custom for all the young people present to carry bouquets of flowers."

Our first mental question was, "Is this the Flower Sermon," of which, like so many others who have lived within sound of Bow Bells all their lives, we have never before heard; or has our old acquaintance of poor Shoreditch prior right to the appellation? And then we began to wonder whether other flower sermons of which we knew nothing might be preached at Whit-suntide in other places; and this led us to Collinson's notice of the grass-strewing in Yatton Church on Whit-Sunday.

The evening in question, June the 7th, was bright and balmy. A long drive through streets of holiday-makers streaming to the

prurer air of our "Northern Heights," through dreary Islington, amid street-vendors of sherbet, "water from the cooler" at a halfpenny a-glass, rows of poor little birds in cages, and stalls of wind-fallen fruit and drooping plants, about which ragged children played; on through the busy regions where looms the dome of St. Paul's, and the massive Bank of England rears its heavy walls; brought us at length to Leadenhall Street, and the doors of the old church of St. Katharine Cree.

Beneath the Gothic arched portal of this old church we passed, out of the din of the bustling street, and with difficulty squeezing our way in, truly we were astonished at the sight that met our eyes. An overflowing congregation filling all the square old high-backed pews, lining the nave and aisles, seated on extempore benches, or standing as thickly as elbows would allow, the crowd extended to the porch and even beyond it. For ourselves, having arrived a little late, we were fain to be content—and grateful for it too—with space for our two feet within the sheltering walls of a certain pew where several other ladies also stood during the whole service.

A goodly congregation of men, women, and children it was, although the service is supposed to be chiefly for the latter. Almost everyone carried a bouquet of bright sweet-smelling flowers, Pinks, Geraniums, or Roses, from sober middle-aged spinsters down to the little children in pinafores; indeed, as Dr. Whittemore said, anyone who felt too proud or too old to carry one must feel out of place at this service.

The text chosen was from Canticles—"The flowers appear on the earth;" and Dr. Whittemore called his hearers' attention to five principal lessons from it. First, God's love in giving us bright and beautiful flowers, not as a necessity to our existence, but as a source of deep and pure enjoyment. This he illustrated by a little anecdote of a Strawberry plant given to the inmate of a hospital ward, where, when the possibility was realised of positively a ripe live Strawberry some day appearing on it, the intensest keenest interest grew up amongst the sufferers there, as hour by hour pale wistful faces watched first for a tender bud, then for the little stony blossom, and then for the formation of the tiny fruit, till the universal joy and expectation were crowned by the ripening of the luscious crimson berry. Secondly, the flowers were to teach us faith in God; for if He cares for them, He will for us. And again, eager listening ears drank in the story of the African traveller, lost in a barren expanse of desert waste, who, casting himself down in despair, perhaps, as he thought, to die, presently perceived at his side a tiny blue blossom. "That," he reflected, "has been set here and tended by our Father in heaven. He will not suffer me to perish." And so with renewed hope and courage he rose, and persevered till the route was found. Thirdly, we were to note God's wisdom shown in the subtle and mysterious mechanism to these delicate structures, in their wondrous formation suited to various soils and many climes, in their gradual transformations from seedlings to fruit-bearing growth, causing them to become sweet food for man or beast, and to renew and multiply themselves. Fourthly, God's benevolence, affording to the poorest and youngest, as well as those better off, a means of bestowing innocent pleasure upon others. And lastly, we were reminded of the lesson that all must learn sooner or later, that as the grass withereth and the flower fadeeth, so all our earthly pleasures, even the brightest and the best, must vanish.

This "Flower Sermon," so far as we have since been able to learn, is not in itself an ancient institution, although perhaps an imitation of the older one.

The special service was originated by Dr. Whittemore himself some sixteen or seventeen years ago, in order to interest young people in nature and its teachings.

We wish it all success, and can but hope that it may live to grow into an old custom, and that it may in its turn find other imitators, for we understand that hundreds of persons who would have listened to the Flower Sermon had to turn from the low porch of St. Katharine Cree on Whit-Tuesday night, for want of space within.—(*The Monthly Packet*.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE beds of young *Cabbages* should be looked all over, and the most forward plants transplanted or pricked out at once. Continue to earth-up *Celery*. Earthing-up a little at a time and often is the maxim of many; with them it is a rule to sow fresh-slacked quicklime among their *Celery* immediately previous to the first earthing-up. It is found by experience that

the *Celery* bed is the best slug-trap in the garden. A double operation, as it were, is performed—the *Celery* is nubbled, and a vast number of slugs are destroyed. The lime, however, must not be applied hot, and it must be shaken carefully into the hearts of the plants, and not in coarse lumps. Let a continual succession of the forward *Endive* be tried for the salad-bowl. Continue tying-up autumn *Lettuce*. Pay general attention to thinning *Spinach*; that to stand the winter may be thinned to 6 inches apart from plant to plant. Sow *Radishes* in a raised bed in a warm situation; these will come in through November, and even up to Christmas with a slight covering occasionally. Remove decaying leaves from amongst crops of *Brussels Sprouts*, *Broccoli*, and similar vegetables, and trench them into the soil in some spare part of the garden that is set apart for early-spring crops. No summer that has occurred within my memory has made the advantages resulting from a system of high cultivation so strikingly apparent as the present. That part of the ground which was trenched two spits deep last autumn bore luxuriant and ample crops of *Strawberries*, while the part of the same garden which was simply dug one spit deep, with a hard and comparatively impervious bottom at the depth of about 9 inches, produced only a few scorched leaves and a very few wretched fruit. In this case manure and other circumstances were the same, except the depth to which the soil was trenched. What is true of *Strawberries* is also true of every other crop whether in the garden or the field.

FRUIT GARDEN.

Of all the operations necessary to promote bearing, the general stopping of fruit trees is, perhaps, the most necessary, yet the most neglected, when the trees are stripped of their leaves; whilst even by some they are neglected at the very period when the rivalry of contending shoots and the darkness occasioned by watery breastwood are so prejudicial to the welfare of the true bearing shoots or spurs. Hence, in the spring, we hear so many complaints of the trees blooming irregularly, "breaking blind," blossoms produced without pistils, &c. I would advise that at this period the trained trees be gone over once more, entirely removing all late growths except from the lower and inferior shoots on Peach and Nectarine trees. These may be kept growing as late as possible in order to encourage strength in those parts, and to equalise the sap in the ensuing year, by the enlargement of their capacities for its reception. Pears will be found to benefit much by this mode of procedure; indeed, the whole of the snags should be left by shortening-back the young spray in June, which is totally removed in the first week in September. Much earlier than this would not answer, for although it might not cause the true blossom-buds of next year to "push," it would cause them to elongate, thereby producing abortive blossoms, and malformations in the fruit. Late-growing Vines should always undergo the same process, at the same time removing every lateral that is shading the principal leaves. This treatment should be applied to Vines in-doors as well as on the open walls.

FLOWER GARDEN.

Every attention should be paid at this period to collecting seeds of popular flowers for mixed beds or masses next year. The *Petunias*, *Salvia patens*, *Pentstemons*, *Calceolarias*, the *Antirrhinums*, with a host of annuals and other plants may at this period be collected. Gardeners in general can scarcely be expected to save many seeds; those who have small gardens may, however, do much in this way. Some of the climbers also produce seeds, such as the *Tropæolums*, *Maurandyas*, the *Lophospermums*, &c. Let the planting of bulbs for very early work proceed directly. Borders or beds deficient in the number of *Snowdrops*, *Crocuses*, and *Narcissuses* should have some introduced. The main planting, however, may be reserved for the early part of November. A few of the earlier sorts of *Hyacinths* may also be planted, covering them 4 or 5 inches in depth, and surrounding the bulbs with sand.

GREENHOUSE AND CONSERVATORY.

Many of our summer favourites will now be going out of flower, if they are not already so, and their place must be studiously supplied with plants peculiar to the autumn months. *Brugmansias* and *Clerodendrons* make an admirable display at this period; some large specimens should be grown later every season for this purpose. They succeed admirably throughout the summer in any common vinery or Peach house, if duly supplied with water and kept perfectly free from insects. Let all large *Orange* trees, *Camellias*, and other large specimens belonging to such structures be brought under cover in good

time. Amongst climbers the *Stephanotis* and *Pergularia* grown on ornamental trellises show themselves peculiarly eligible to be introduced here on the decay of other flowers. The *Jasmines*, also, especially *Jasminum Sambac*, are valuable thus treated. They are to be had in flower on pot trellises continuously from May; the principal treatment consists in stopping every luxuriant shoot as soon as it is a few joints long. The *Francisceas* are very ornamental plants, and well adapted for those who have only one house. *Franciscea Hopeana*, although an old kind, is still very useful, and is, besides, very fragrant. The young rambling shoots should be constantly stopped; doing so will induce them to bloom freely and remain in a bushy state. Stout young *Mignonette* plants, potted immediately and kept under cutting treatment for a week or more, will flower well in November and December, when every little matter of this kind will be acceptable. The *Cyclamen hederifolium* is a pretty little pot plant for those whose space is limited; indeed, the whole family of *Cyclamens* are particularly ornamental and easy of cultivation. The *Linum trigynum* is a pretty winter flower, one or two should grace every collection. As before observed, continue daily to house everything likely to suffer from the autumn frosts.

STOVE.

Several of the *Dendrobiums*, *Aërides*, *Saccolabiums*, and *Vandas* will still make considerable growth in a high temperature with much moisture, but take care to increase the amount of sunlight. *Cattleyas* should not be encouraged to grow after this time if good blooms are required. Young specimens may, however, still be kept growing for the sake of size. *Stanhopeas* which have made robust growth should have the supply of water diminished, and have a lower temperature with less shading; those still growing may be watered freely.

COLD PITS AND FRAMES.

These should now be furnished with bulbs of the most approved kinds for forcing, Pinks in variety, particularly the *Anne Boleyn*, *Neapolitan* and *Russian Violets*, and sturdy young plants of *Wallflowers* in variety. *Mignonettes* should be thinned in due season. Ten-week Stocks should be sown for pricking into pots by the end of next month. *Cinerarias* should now be repotted, and *Calceolarias* parted, placed in 3-inch pots, and plunged close to the glass in some cinder ashes in a cold pit or frame.—W. KEANE.

DOINGS OF THE LAST WEEK.

WHAT a pity it is that fine sunny weather should ever do harm! It is so much more pleasant to move about when the air is dry and calm, and the sun bright but shaded by occasional clouds. Many felt this during the week when caught far from home, or obliged to remain under what shelter could be obtained during the heavy rains that have visited us, after similar accumulated vapours had been condensed and soaked the battlefields of France. Would not these dread battles, by the disturbance in the atmosphere by the discharge of artillery, have something to do, naturally speaking, with the free falling of the rain? We know how all our weather-glasses fell without any seeming cause at the last awful bombardment of Sebastopol. Some of our volunteers, who have got their fair soakings at Wimbledon, have half-seriously commented on what a good firing of cannon might do for us in such a dry season. Further evidence is wanted before we can set down as cause and effect what may after all be a mere coincidence. We were glad, however, to see the showers falling, as they have done so much to cleanse and invigorate all vegetation, to give a green colouring to our meadows, and to make our lawns like green carpets. The wind that reached more than an equinoctial gale on the night of the 8th and part of the 9th did considerable damage in breaking and scattering limbs and branches of trees, rendering the flower garden less lovely, and sending down lots of fruit far from being ripe. These, however, would suffer less from the fall, owing to the softening of the ground by the rain. A rising barometer seems to indicate that the wind and the rains will soon be over, or be more gentle.

KITCHEN GARDEN.

Almost everything is thriving. Brussels Sprouts, Borecole, and Broccoli seem to grow like magic, and all the more from the ground between the plants being stirred with a fork. As a class (and even our cottager gardeners, who often beat the professed gardeners in vegetables), we are not fully aware of the great advantage this stirring gives to free growth. The late-put-in small plants of all sorts of Greens, if they do not

become very large, will be fine cutting in the early spring months. By the means referred to last week, and followed by the nice showers, we find Cabbages and Cauliflowers are now almost entirely free of the fly which settled on them in clouds. We have two nice pieces of early Cabbages, growing well, for early cutting next year, and will ere long follow with the main quarter and younger plants, having removed the Onions on purpose. The Onions, though plentiful, are much smaller than usual, as they were never thoroughly moistened from the time they were above ground until they were pulled up when all growth was over. We always had a difficulty, treat them how we would, even bringing poverty of soil to our aid, in securing a good supply of pickling Onions, but there will be no want of picklers this year.

Cauliflower, instead of coming forked and sprouting, as it was forced to do in the dry hot weather, is now vigorous, and turning in with beautiful white heads, so useful for table in the autumn months. Our seedling Cauliflower intended for next spring is just fairly up, and we shall scatter a little charcoal dust among it, as it looks as if the rains had been heavy enough for the little plants. Having these too early is generally anything but an advantage, as Cauliflower plants are next to lost if they show any signs of forming a head before the plants have attained a good size. When the heads are forward in autumn they are apt to bolt in winter and spring, and thus prove worthless.

We have found, on the whole, no plan better for early cutting than placing a lot of these plants under hand-lights next month. We generally put nine under a hand-light, and thin to four or five in spring. We have tried pots, repotting and then planting out, and it is a good plan where room can be found in a cool house, an orchard house, cold pit, or frame from which rats and mice can be excluded; but on the whole our plants put out under hand-lights in autumn, and attended to in winter, generally beat all other competitors where no artificial heat was given. Once we were hard driven, rats having nearly cleared off our fine young plants in winter, and we sowed in heat, pricked out in gentle heat, then transplanted in an earth pit—such as we use for early Potatoes—with a little bottom heat, and covered at first with old sashes, straw frames, &c., and thus we obtained fine early gatherings, and the mischief the vermin did was never known at the dining-table; the additional trouble, however, was considerable. We have also had plants potted at the end of this month and treated with a little extra heat until they were strong, come in early; but on the whole, where nothing but the heat of the external atmosphere is available, we have a decided leaning, for the first crop, to planting out under hand-lights, or little wooden boxes with a moveable glass top. No doubt the French cloches would do equally well, but of these we have had no experience.

The dull dripping weather enabled us to plant out the last of our *Celery*; and as the plants were fine and strong, and had been pricked out rather thinly, they lifted with large balls full of roots, and the suckers being removed, they were planted in well-prepared beds, which, when finished, were little if at all below the general ground level. These, being well watered, have shown no signs of distress in the brightest sun, but are pushing their roots freely in their new quarters. We never planted out so much *Celery* so late, but it looks now as if planted in July. Circumstances must often regulate our practice. In such a season we never could have obtained water to keep the *Celery* in health if it had been turned out in beds and rows, but it was kept healthy with little water and shading by letting it remain rather thickly until the 5th inst., when the weather changed. Most of it has been planted three rows in a bed, but as a piece of Peas gave no sign of being near any longer, we had the ground cleared and 15-inch-wide shallow trenches made, with 2-feet spaces between, and there we planted in single rows, the soil with the dung added being quite up to the general level. This is often a great advantage in damp, drizzling winters, as damping and rotting the plants are avoided. These, being strong plants, will show little signs of the late planting by the first weeks in November.

We forgot to state, that though the Onion ground, after *Celery*, was well manured, yet we shall add a little rotten dung and a dressing from the rubbish-heap before half trenching the ground for the Cabbage crop—all the more essential when we generally allow these Cabbages to occupy the ground for eighteen months, that is all next summer, and through the winter until the following spring. In some of our earth pits which we use for bedding plants, we have lots of the Little Pixie Cabbage and the Early Elm Savoy hearting nicely, both

of which will come in before the earliest Coleworts, and as they will be liable to the attacks of depredators, we shall use them up before the cold weather sets in.

The dry weather, as in the case of early Potatoes, which never were finer, has made little impression on Carrots, Parsnips, and Beet, which we have rarely had finer. Later-sown Carrots have not done so well. We planted out lots of Lettuces and Endive to stand the winter, and sowed at the foot of walls to give them a chance. Hoed between the autumn-sown Spinach and Onions, and lest the autumn should be fine, and the Spinach become rather tender, we shall sow a few rows more, which will be useful in spring if the frost prove very severe.

Rubbish-heap.—Mentioning it above reminds us that in damp days we have had ours made up afresh, mixing a little littersy dung, and a sprinkling of rough salt with earth from pots, weeds, Cabbage stalks, &c., and covering it all over with earth, so that what escapes from the heating may be retained. We are often surprised from whence such a huge heap of scores of cartloads comes. If we had rich waters to spare, we would have added them, and also some loads of lime if to be had. Built up in layers, and cut down from top to bottom, the rubbish-heap thus formed and heated will be an excellent dressing to wheel on in the winter months. Cottagers would greatly add to their supply of manure if they never allowed weeds, Cabbage or Cauliflower stems, &c., to decay without being covered with earth.

FRUIT DEPARTMENT.

The wind has thrown down even from our dwarf trees many fruit far from being ripe, and, therefore, they will be more liable to shrivel before being used. Apples and Pears should in general be gathered before they are fully ripe, just when the pipe are about half coloured. They will thus be more juicy and have a richer flavour. Before this appears in type we shall have been using for three weeks in first-rate condition that fine autumn Pear, Williams's Don Christian, and that from one espalier tree bearing very fine fruit for the season. Such a Pear if allowed to hang until even nearly ripe, would not last many days. We have gathered the most forward, if not every day, at least every other day, and kept them two or three days before using them, just when full of their aromatic rich juice. The first we had we sweated a little in a little extra heat, covering them up to prevent the juice of the Pear escaping. Even when we give no extra heat, we prefer covering this rich Pear when gathered. We had a sample of small fruit of this Pear from a standard orchard tree, the possessor saying he had two or three bushels of it, and they all came in together. They could be of no use except for children, or those who liked a half-rotten Pear. They were as mealy as Potatoes, marked on the skin, and quite unfit to send to table. In some seasons, by careful picking, we have had this Pear in use for six weeks. If we had left it to itself it would not have been in use for more than six days. We mention this Pear merely as an example of what our amateurs might accomplish with favourite Pears and Apples—the Kerry Pippin Apple, for instance, and they can do far more than gardeners in general can find time and means to attend to. We have great faith in many improvements in gardening coming from and through enthusiastic amateurs. Even Peaches and Nectarines against walls were thrown off by the gale of the 9th and 10th. Perhaps what vexed us most was the number of fine fruit of the Reine Claude de Bavay Plum thrown from a bush tree, and these so green as not to be fit even for cooking. We expected them to be fine by the end of the month.

We alluded to orchard houses last week.

In late vinerias we are using a little fire heat to perfect the ripening, and keep a drier atmosphere. Ere long we shall, as the best we can do, throw some litter over the borders of the late house, especially to keep the heat in and the wet partially out, as the late rains have given pretty well enough of moisture.

ORNAMENTAL DEPARTMENT.

Taking plants under protection must now be thought about. The lawns are now beautifully green, and the flower beds stood the rains well until after the gale of the 9th. But for our bush-staking, our beds would have been nowhere. Large heads of scarlet Geraniums were nipped off and carried away scores or hundreds of yards. After all, a sunny day or two will make the beds very presentable again, though we hardly expect them to be so massive and rich as before the gale. That they suffered comparatively so little we attribute chiefly to two causes—first, the fastening the plants with small brauchy twigs; and se-

condly, having picked the beds over, so as to remove the faded blooms before the gale and the heaviest rains came. Even as it was, the rains dashed and discoloured many trusses of bloom, which will want picking or removing. Picking over a Geranium bed involves care and discrimination. Some pickers, if not looked over, if there are a few faded flowers in a Geranium truss, will forthwith cut it over and put it in their waste-basket, instead of neatly taking out the decayed flowers with the point of a sharp knife. The other day in such baskets we found trusses of Geraniums with from twenty to thirty small flowers only seeking room and time to expand and show their beauties. To cut off such where massive colouring is required is worse than carelessness.

All plants to flower in winter can now hardly have too much sunlight. Such fine plants as Euphorbia jacquiniiflora and Poinsettia pulcherrima, if full grown, should have less water and all the sun possible to set the flower buds. Sowed some hardy annuals to stand the winter, and a few, along with Mignonette, in pots to bloom early in spring. Proceeded with potting and cutting-making as previously detailed, propagating most of what will be wanted for the flower garden, except Calceolarias. Pricked off herbaceous Calceolarias for spring-blooming.—R. F.

TRADE CATALOGUES RECEIVED.

James Veitch & Sons, Royal Exotic Nursery, King's Road, Chelsea, London, S.W.—*Catalogue of Hyacinths and other Bulbous Roots.*

William Paul, Waltham Cross, London, N.—*Rose Catalogue, 1870-71.*

E. G. Henderson & Son, Wellington Road, St. John's Wood, London, N.W.—*Autumn Catalogue of Bulbs and Flower Roots.*

J. House, Eastgate Nursery, Peterborough.—*Select List of Hyacinths, Tulips, Crocuses, Narcissus, Gladiolus, and other Flower Roots.*

T. Binyard & Sons, Maidstone.—*Select List of Dutch Flower Roots.*

Butler, McCulloch, & Co.—*Catalogue of Dutch Bulbs, Flower, Vegetable, and Agricultural Seeds.*

TO CORRESPONDENTS.

* * * We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By doing so they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

CUTTINGS OF RED-BERRIED ELDER (*North*).—We do not know where you can obtain them.

RIPE GRAPES SHRIVELLING (*West Cumberland*).—The berries you enclosed are dead ripe, and if the inside border is dry and the house heated the berries are likely to approach the raisin state. Watering and mulching the roots and a moist atmosphere we think would stop the shrivelling.

MISGAT OF ALEXANDRIA GRAPES SHRIVELLING (*Janah*).—We think that the reply we have given to "*West Cumberland*" is applicable to your case. If you mulch the border and water it in dry weather—in your case it is outside—and keep the air of the house moist, the Grapes will not shrivel, and those of the Lady Downe's be larger.

STEPHANOTIS FLORIBUNDA FRUITING (*F. L.*).—It is not unusual for it to ripen its fruit in this country. We have remarked more fully on the subject on page 397 of our last volume.

DESMODIUM RACEMOSUM.—J. V. wishes to know if anyone has seen this shrub in bloom, or whether it is marvellously good anywhere except in a trade catalogue. It is not a newly-discovered plant, for it is described by Thunberg among other Japanese plants.

DIAMOND PEACH.—This Peach is in the catalogue of Mrs. Pontey, of Plymouth, who, in answer to my inquiries, tells me the tree was raised from seed by Mr. Sharland, who was gardener at Werrington Park, near Launceston, about twenty years ago. The variety is well worthy of a notice in the "*Fruit Manual*."—V. W. POPHAM, *Portsmouth.*

SPOT ON MELONS (*Somerset*).—We are unable to account for the spot on the Melon, but as the fruit arrived at maturity the spot could not have been of material consequence. The leaves going off after the fruit is ripe is only natural, though sometimes by cutting back the shoots which have produced, fresh shoots will start and bear a second crop of fruit; but for this to be the case, the first crop of fruit must be ripe and cut early in July, so that the fresh shoots may be formed and fruit showing early in August. We think the plants are exhausted, hence their dying

off. The leaves are, no doubt, scorched through allowing the sun to shine powerfully on them whilst wet. To prevent it give a little air earlier in the day, and slight shading during very bright weather, especially when it is preceded by a period of dull weather. The thirteen fruit, some the size of walnuts, and others as large as ducks' eggs are early enough to ripen, but we should reduce the number at least one-half; indeed, four fruit on a plant are as many as we have found swell and ripen well. It is not sufficient that each fruit be on a separate tertiary shoot, but one fruit to each primary shoot is necessary to secure finely-swelled fruit. The temperature of 76° in the morning is too high by 1°, 65 being a very good temperature for Melons in the night when in a bearing state, and we think you have made some mistake. Perhaps the temperature of 76° is when you give air—8 A.M., or later. If so it is right.

LAUREL SCREEN FOR ROSES (F. J. K.).—The screen of Laurels to the north of your standard Roses will not injure the Rose trees unless they are so near as to interfere with the Rose roots by robbing the soil of nutriment, but if not nearer than 4 feet they will do no harm. We would keep the Laurels well cut back on the side next the Rose border, and their roots may be kept within bounds by taking out a trench about 2 feet from the stems of the Laurels, cutting off all roots there to the same depth as the Laurel roots are situated. This may be done in spring before they begin to grow.

PYRAMID APPLE AND PEAR TREES UNFRUITFUL (Idem).—There is nothing strange in your trees not fruiting. They have all gone to wood, and the height, 10 feet, indicates to us that summer pruning has been totally neglected. We advise you to take out at 2 feet from the stem a trench round each tree as soon as the leaves begin to fall, cutting off every root great or small, and whilst the trench is open cut with a spade under the ball towards the centre of the tree, severing every root at 15 inches beneath the surface. Fill up the trench, and prune when the leaves are all off, so as to form a well-shaped plant. If the ground is damp we would take up and replant each tree on a raised mound, or lift it with a ball, place it on the level, and put soil against the ball so as to form a cone twice as wide at the base as it is high. If the height be 18 inches the soil should slope away for 3 feet from the stem all round. Mulch with litter 2 or 3 inches thick to protect the roots from frost; they should not be covered more than 3 inches deep. This will check the growth. Whichever course you pursue it will have one result, preventing gross growth for the next two or three years at least; and by keeping the shoots pinched in summer, taking out the point of each when it has made six leaves, again at the second leaf from that, and then to one afterwards throughout the summer up to the middle of September, in the following year we think you will have fruit. There is no necessity to take up the trees and replant unless they have grown beyond bounds and are irreclaimable. We presume the Pears are on the Quince, and the Apples on the Paradise stock. Apples and Pears on these stocks are with us bearing heavy crops this year. Pyramid Plums are also loaded with fruit.

POND FOR GARDEN USE (Idem).—The pond for securing water for the garden in summer will be valuable. Its size will be entirely dependent on the extent of the garden. For ordinary purposes, by which we mean watering in dry weather, we should not have a pond less than 18 feet by 3 feet, and 6 feet deep, but twice that size would not be too large if you are entirely dependent on filling it during the winter months; but if you can command a supply with every fall of rain, then the size named would answer very well. Now, before rainy weather sets in, is the proper time to do this kind of work. The sides and bottom will need to be made watertight either by puddling with clay, or by walling it round, plastering with cement, and backing the wall up with clay rammed firm.

AZALEA LEAVES BROWNED (J. Clark).—The leaves appear to have been browned at the ends through allowing the sun to shine on them whilst wet, and they look as if water had stood on them almost constantly. One of the leaves has every appearance of having been infested with thrips. The remedy in the latter case is to fumigate with tobacco, and in the former not to syringe so heavily; indeed, at this time of year it is not necessary to syringe. Admit air freely. Surely something must be altogether wrong in the soil or the treatment, otherwise six plants out of ten would not have died. See to the drainage of the pots.

LUCCIA GRATISSIMA LEAVES FALLING (Subscriber, Dublin).—The leaf sent has the usual appearance when the roots of this plant are not in a healthy state. In a pot the plant's leaves always have a tendency to fall, especially when the pot is small. It is well, therefore, to place it in a large pot, or, better still, plant it out in a bed or border in a conservatory. Peat and loam in equal parts, both fibrous, and a fourth of charcoal in lumps between the size of peas and walnuts, with a sixth of silver sand, form a very good compost. Good drainage is necessary. Care should be taken not to overwater; indeed no water should be given as long as the leaves do not flag, but before they do this give a good watering. Watering constantly in dribblers is ruinous to it. The leaves attain but a small size and have a brown dingy appearance when the plant is kept deluged with water.

TACSONIA MOLLISSIMA NOT FLOWERING (Idem).—We cannot account for your plant not flowering, as you do not afford us any data. We have it planted out in a greenhouse border in a compost of equal parts of loam and leaf soil, with a free admixture of sharp sand. The shoots are trained about 14 inches from the glass, and from 3 to 6 inches apart; it has been in bloom since May, and is now finely in flower, having several fruits about the size of an egg. Water has been given as required to keep the leaves from flagging. That is all it has had or seems to require.

CAMELLIA POTTING (Idem).—Your plant with all its buds well set would, we think, swell them and flower all the better if it were left alone for the present, deferring the potting until the flowering is over. There is a risk of the buds falling if the potting is done now, though it may be performed now, care being taken not to injure the roots.

POTTING DRY BULBS OF LILIUUM AURATUM (An Amateur).—No Lilium ought to be kept out of the ground all the winter. If by dry you mean imported bulbs, put them at once in a compost of one-half fibrous loam, one-fourth sandy peat, and one-fourth leaf soil or old cow dung, with a free admixture of sharp sand. Drain the pots well, and pot so that a space of from 14 to 2 inches will be left below the rim for top-dressing in spring, or when the shoots are fairly above the rim of the pot. In potting cover all but the crown of the bulb. For dry bulbs place a little silver sand at the base of the bulb and all round it. After potting water gently, but not for some time if the soil be moist, and place the bulbs in a cold

pit or house secure from frost, watering but little, if at all, so long as the soil remains moist. When the shoots appear water more freely, and top-dress with the same compost as that used in potting, when the shoots are sufficiently advanced. When growth begins place the pots in a light, airy position, and as near as practicable to the glass to allow room for growth.

GATHERING MEDLARS (N. C. W.).—They will not be fit to gather for some time. They are usually not ripe until the leaves begin to fall; but when they put freely from the tree they should be gathered and stored in a single layer in a fruit-room, and all they require is to be looked over, taking out any that decay, and securing them as they ripen. No use of which we are aware can be made of the fruit now falling. If bruised it will not keep till mellow, but will decay prematurely. Medlars are not eaten until they have undergone incipient decay, and are then much relished by some. Of the grafting point we have no experience, but we do not see why it should not be kept in a vessel like any other point for occasional use.

VINES INJURED (E. J.).—No doubt the burning of the leaves by a fire in the house greatly injured the Vines, and the Grapes especially. Still, as the leaders that chiefly suffered made fresh leaves, we are doubtful if that would cause the berries to rot off now. We are inclined to think it must have been the result partly of a close damp atmosphere. The border having been made so recently, and the season so dry generally, we can hardly think the evil can be owing to too much moisture there. If it should be at all owing to the roots going down into a bad soil, we do not see how bricking-up the back of the border inside and the front of the border outside would arrest the evil. The roots, prevented spreading, would be more induced to go down. We would mulch the surface of the borders, and give the Vines a fair chance another year before disturbing the roots.

HEATING BY HOT WATER (Timber).—The top of your boiler must be lower than the lowest heating pipe in the house; if a foot or two lower still all the better. The boiler will be best placed at one end. Covering the pipes for bottom heat thinly with rubble will be the most economical. For early spring work 2-inch pipes below and two above will do. For winter work 4-inch pipes will be necessary, unless you can cover the glass in severe weather. For all particulars, see answer to another correspondent in the second column, page 121.

FRENCH MARIGOLDS (R. N.).—Very like many others, and not equal to the best now cultivated.

HEATING BY GAS (E. L. J.).—The plan will answer very well provided you have a little door for lighting the gas burners, and use burners in proportion to the size of the place to be heated. There will be little danger of a stout slate cracking. If all is made secure—that is, the slate and covering, no gas can escape into the house. Cocoa-nut refuse would be the cleanest. The bottom of the pit being almost close to the slate, you will succeed with seeds and propagating best by having small moveable glass sashes over the bed. Without top heat we do not think Brazilian Ferns will thrive in such a place in winter.

FUEL FOR HEATING GARDEN STRUCTURES (Mrs. P. A.).—It is difficult to advise you, because we are not decided ourselves as to what is most economical, without taking circumstances into consideration. No doubt those who recommend Welsh smelting coal as, though expensive, the cheapest in the end, have so far reason on their side, that this kind of coal is very strong, and gives out a great amount of heat. But when you come to have rapid changes of weather from cold to warmer, or you have a stoker or fireman who now and then puts on too large a fire of this strong coal—and to keep things right he must either open the furnace door that the cool air may play over the fire instead of under it, or take the fire partly out—in either case there will be a waste of this expensive fuel, this counteracting most, if not all, of its extra advantages. The amateur who attends to the fire himself will find it cheapest to use the best fuel. We do not think the possessor of several hothouses, who must employ others to do such work, will find the dearest fuel the cheapest. If fair fuel is used, if a mistake occurs there is not so much loss. As you refer to coke, it has a great advantage beyond mere economy—the little smoke it makes. We think, on the whole, coke would be the cheapest, but there should be hot coals used for lighting and adding a little at a time, nuts being small nodules of the best and middling coal freed from the more dusty matter. Such plants as Virginian Stocks, Candytufts, and Chinese Chrysanthemums will often bloom for a month or two after the Geraniums are injured by frost. Plants of Lamplights, Hollies, Cottonasters, and Snowberries turned out of pots would also look well; but for much flowering you must depend on Snowdrops and Crocuses.

STANDARD FRUIT TREES (Pomas).—You do not state what part of the country you live in, or what you chiefly want the fruit for, whether for table or kitchen. We shall place the first four as most useful for the table: Apples; Devonshire Quarrendin, Kerry Pippin, Cockle Pippin, Blenheim Pippin, Cellini, Emperor Alexander, Kentish Filbasket, Bedfordshire Foundling, Northern Greening, Pears; Citron des Carmes, Williams's Bon Christian, Louise Bonne of Jersey, Aston Town, Burré de Capiaumont, Bishop's Thump, Winter Nellis; Cathlic and Winter Franc Real for stewing. Plums; Green Gage, Purple Gage, Jelferson's, Kirke's, Orleans, Goliath, Washington, Victoria, Pond's Seedling. These are mostly arranged in the order of their ripening. All the Pears, except the last two, will do for table. Of Apples, Cellini would be between table and kitchen, as when good it comes in for both. The first four Plums are good for dessert and also for preserving. The Diamond and Damson are good for cooking and preserving. The best time to plant is as early as possible at the end of October or the beginning of November, as soon as the leaves change.

VINES AND VINE BORDERS (J. Jackson).—In raising the roots of Vines, begin by a deep trench at the extremities, and carefully pick out the roots of the Vines as you go, keeping them covered and moist, and replant again as soon as possible in sweet mellow loam, covering from 6 to 8 inches. Let the border be from 20 to 24 inches deep, and well drained. In such a case as yours, however, where the luncches are only getting smaller, we would do nothing of the kind. We would merely take a lighter crop for a year or two, fork away as much of the surface of the border as would not hurt the roots at all, and then surface with fresh soil with a sixth part of lime rubbish and a few bushels of hoiled broken bones. We come to this conclusion as you are so sure the border is not sodden or sour. In such dry summers as we have had, almost every outside border

would have been better of a good manure watering, especially if there was drainage.

COW DUNG FOR VINE BORDER (H. W.).—Cow dung is a good mulching for Vine borders when put on, not fresh, but dry and sweet. If that cannot be obtained, we would prefer horse droppings as fresh as you like. Cow dung, if fresh, is too close. It matters little when applied. A covering all summer would save watering considerably. After it has been on some time it is as well to rake it off, or scrape it off, and add fresh. There are various modes of making a loose gravel walk smooth. You might consolidate it with tar, so as to make your gravel walk into tar pavement, as described at page 165. You might gain the same object, as we did years ago in some cases, without all the trouble of heating, boiling, and mixing, by merely using enough of tar in its natural state to moisten the gravel, and then covering with fresh and rolling down, so that the surface should be just embedded. We would do this in one of two ways in such a case as yours. First, if we could obtain enough of fine sandy gravel for a surfacing, we would roll the present walk hard, place on it a layer of tar, say one-eighth of an inch thick, roll with a wet roller, apply the surfacing soon after, and roll again. If we could get no fresh gravel we would sift the best surface gravel, passing it through a half-inch sieve, tar what was left, and put the sifted surface on. We never could see much advantage in boiling tar. The tar will run and mix admirably without boiling. The simplest mode of making such a pebbly rough walk smooth is to collect a lot of clay, dry and riddle it, roll the walk, add a surfacing of the clay, which will fill the interstices, and then cover with a slight surfacing of rough sand to prevent any of the clay adhering to the feet. We have used thick clay water, or rather clay mud, for a similar purpose, but it requires more time. Such rough walks as you describe are unpleasant, but they are better than smooth walks that stick to the feet in damp weather; the sand-surfacing will prevent that.

PROFITABLE VEGETABLE CROP (Gardener's Friend).—Your ground may fallow for two years will be suitable for most kinds of vegetables, and we think, all things considered, that Potatoes are most likely to repay you. The ground should be manured now, or between now and November, and we would dig it well and deeply, and if the soil is stiff, throw it up in ridges for the winter, that frost may act on it. In February or dry, frosty weather—if such do not occur, then in dry weather—turn over the ground with a fork, level it, and when the ground is in good working order plant the Potatoes as soon after the middle of March as you can. Having manured in autumn, it is not necessary nor desirable to manure at planting. As to kinds, we can recommend two second early, ripening early, excellent both before and after they are ripe, and keeping late. They are Lapstone (a kidney) and Early Oxford (round), both first class croppers. Our Potatoes this year are a very fine crop, both in quantity and quality.

WINTERING GERANIUMS IN A POULTRY HOUSE (Idem).—We fear your chances of wintering bedding Geraniums in a poultry house are very small. Your best plan would be to take up the old plants, strip off every leaf, keep them in the sun for a few hours to dry, and then store them in your house in dry sand. They will need to have the root portion buried in the sand, as well as a portion of the stems, but the soft succulent parts ought not to be covered. You must give air every fine day, and in frosty weather protect with a covering of dry hay or other dry material, removing it when the weather is mild. In March you may place the plants in pots or boxes in sandy soil, and with light and air they will begin to grow, though they will be better of a frame and a gentle hobdab.

FRUIT TREES FOR A GARDEN (E. B.).—For the establishers, we think Apples and Pears are best. *Dessert Apples:* Early Red Margaret, Kerry Pippin, Cellini, Adams' Pearmain, Golden Pippin, Margil, Nonpareil, Ribston Pippin, Sykehouse Russet, Court of Wick, Keddleston Pippin, Cockle Pippin, Downton Pippin, Braddick's Nonpareil, Old Nonpareil, Cox's Orange Pippin, Wyken Pippin, and Pears' six Plate. *Kitchen Apples:* Cox's Pomona, Keswick Codlin, Lord Salfield, Alfriston, Bedfordshire Fording, Pamelow's Seedling, Beauty of Kent, Northern Greening, Norfolk Beefing, Blenheim Pippin, Kymor, and Winter Majestic. *Pears:* Beurre Giffard, Citron des Carmes, Fondante d'Automne, Comte de Lamy, Beurre de Capiaumont, Bergamotte Esperen, Louise Bonne de Jersey, Forelle, Marie Louise, Williams' Red Chretien, Thompson's Seckle, Napoleon, Haeon's Uncomparable, Beurre Rose, Beurre Diel, Jean de Witte, Glon Morecan, Ne plus Meuris, and Beurre de Ranee. These we have found answer well. If you wish for a stewing Pear, C'atillac will suit. We do not consider Plums so well on espaliers, as they do not readily submit to horizontal training. They are best grown as pyramids or bun-bush, and kinds that so succeed are July Green Gage, Orleans, Kirke's Jefferson, Golden Gage, and Cox's Golden Drop. *Cherries,* if wished for in the open garden, are best treated as pyramids, in which way they bear profusely. *Bisarran Napoleon, Black Eagle, Eton, Florence, Knight's Early Black, May Duke, and Late Duke, the Morello* being a very handsome and exceedingly prolific pyramid. The east wall we should devote to Plums, Pears, and Cherries. *Plums—Green Gage, Jefferson, Cox's Golden Drop, Pond's Seedling, Victoria, and Prince of Wales. Pears—Beurre Diel, Flemish Beauty, Pisse Colmar, Leon le Clerc, Marie Louise, Winter Ne plus Meuris, Glon Morecan, and Ne plus Meuris. Cherries—Early Purple Gage, May Duke, and Black Chreissan or Tartarian.* For the fence with a north aspect, Morello and Tradescant's Heart Cherries are the only fruit trees likely to succeed, but we have grown excellent Red, White, and Black Currants against such a fence, and have them now in fine condition.

EMPEROR STOCKS (A. Z.).—They are biennials, and sometimes of longer duration.

SCARBOROUGH LILY TREATMENT (C. R. H.).—From the description we think that is the common name of your plant, *Vallisneria spiralis*. Unless you wish for more plants, we would not divide the plant, for we do not think any bulbous plant can be effected with but a few bulbs in a pot. We have it now with from six to a dozen and more spikes in a single pot, and the effect is very fine. If you wish to have more plants, then you may divide it into as many parts as there are bulbs, and pot each separately, employing pots twice the diameter of the bulbs. As much soil and as many roots as possible should be secured with each bulb. Drain the pot well, using a compost of two-thirds fibrous loam, and one-third leaf soil or old cow dung, with a sixth of silver sand. Pot firmly, the soil being moderately dry, and with the neck of the bulb level with the rim of the pot, the bulb being covered that depth with soil. Set the pots in a greenhouse in a light airy position, and keep the soil moist at all seasons, but never very wet, though when the plant is growing freely abundant supplies of water should be given. In July and August give plenty of

light and air, with no more water than will keep the foliage fresh. It is a splendid plant, of very easy culture, and one of the most useful for autumn display, doing well as a window plant, and not suffering to any great extent when placed in rooms during its flowering period.

RICHARDIA ETHIOPIACA TREATMENT (W. N.).—It thrives in a rich, light, fibrous loam, and though requiring plenty of water when growing it needs good drainage. A small pot for the size of the plant is desirable. When it has done growing, or say from June, or if in a window from August, keep it dry, not giving water to any great extent for the next three months, and when the plant begins to grow again water it copiously, and when it is growing freely set the pot in a saucer of water, or in a window in May, June, and July, when its growth will be complete; then keep it dry three or four months, and water it again according to the fresh growth, increasing the quantity as the plant grows. A situation exposed to the full sun is necessary. In winter keep frost from it.

TROPICOLM TUBEROSUM and PENTAPHYLLUM FLOWERLESS (Idem).—The cause of their not flowering is no doubt the exposed situation, but as the soil is dry, that may have something to do with it. Try a mulching of leaf soil or well-decayed manure in autumn, and copious waterings in spring and early in summer. Train the shoots near the wall so as to give them the benefit of its warmth, syringing freely on the evenings of hot days.

EVERGREEN TREES FOR SCREEN ON A LIGHT SOIL (Idem).—No evergreen shrub will bear exposure without some other shelter, except Gorse. Both the single and double Gorse are very ornamental, and will stand any amount of exposure. *Pinus austriaca* is the best evergreen tree for shelter, and by planting it you may have all the hardy evergreen shrubs without fear. If you only wish for a screen, then we advise Holly or Yew, both of which are excellent, and you can cut them in as much as you desire. The latter is the best screen or hedge known.

CLIMBERS FOR A SOUTH-EAST WALL (Idem).—*Jasminum nudiflorum, Lonicera flexuosa, Clematis Fortunei, and C. Jackmanni* would answer very well on your wall, and so would *Ax-bone, Queen and Dundee Rambler* Roses, but you should manure the soil well, and if it is dry water well in summer. If you wish for evergreens, *Escallonia macrantha, Garrya elliptica, and Crataegus Pyracantha* will suit.

LARGE MELON (John Leslie). We know of no record of a Melon weighing 15 lbs. 10 ozs. What of the flavour? And what is it like in shape—netted or not, round or long, ribbed or not, and where did it originate? Large Melons, as a rule, are no better flavoured than Turnips, but we have known some persons eat and admire for its flavour an Orange Gourd weighing over a hundredweight. Is not your supposed Melon a Gourd?

WHITE SUBSTANCE ON BARK OF BEECH TREE (Rep. —).—The substance on the Beech tree is not a fungus, but the produce of a *Coccis*. It has, however, been described as a fungus by Fries under the name of *Psilonia nivea*.

INSECTS (C. C. E.).—The insect you have sent, said to devour wireworms, is itself a wireworm—Oat is, it is the larva of *Blater fulvipes*, or a closely allied species. It is distinguished from the true wireworm by having the extremity of the body ending in a point with two small incisions on each side. Nothing has been recorded of its precise habits, and it may possibly feed on other larvae, which is, however, at least doubtful. *A Constant Subscriber*. The Apple twig is badly infested with the too common woolly American blight (*Aphis lanigera*). The infested parts should be well washed with hot soft-soap suds with lime and foot mixed, forming a stiff solution, applied with a soft brush so as to cause it to enter the wounds of the bark. The Thorn twigs have swellings like galls with minute holes, but we can find no trace of insects within, and believe them to be a vegetable gout-like disease. The Oak leaves are covered with the Oak-spangles, which are real galls formed by *Cynips longipennis*.—I. O. W.

NAMES OF FRUITS (H. M. P.).—Both Plums are Guthrie's Golden. *E. C. Oakham*.—Your Plum is evidently a seedling which has not yet been named. *(D. X. Z.)*—*Van Mons' Red (C. Charrbon)*.—*Yellow Imperial (A. B. A)*.—Your Plum is McLoudlin. *(C. Charrbon)*.—We cannot identify either the Apples or the Plum. If the Apple is not named, Summer Ribston is very applicable. *(C. B. Ware, H. M.)*.—The Apple is certainly not Fine Apple Russet. Send it to Mr. Rivers, and he will probably be able to compare it with some in his collection.

NAMES OF PLANTS (T. S. Subscriber).—We cannot undertake to name a plant from even a green leaf, and you have sent a dead one. We require to see a flower. *(H. W.)*—What you call "the Toad-plant" is *Stapelia normalis*, or Regularly-spotted *Stapelia*. "*A Subscriber's*" plant is the common Hemp (*Cannabis sativa*), the specimen sent being female. It usually grows very much taller, but the circumstances it was placed under would induce it to be so dwarf. *(July)*.—1. *Nephrolepis exaltata*; 2. *Selaginella Braunii* (S. pubescens of gardens); 3. *Asplenium flaccidum*; 4. *Selaginella Kraussiana*, the S. tortuosus of gardens; 5. S. Martensii. *(S. W. Tongue)*.—We do not identify the Madeira creeper from the solitary leaf sent us; but should she succeed in blooming it, we would then gladly endeavour to assist her by naming it. We should consider a loamy soil, with sand, without any peat, as best fitted for it, together with greenhouse treatment. *(Chulcar Fallon)*.—A pretty Creeper, which we have not yet recognised.

POULTRY, BEE, AND PIGEON CHRONICLE.

KEEPING POULTRY AS A BUSINESS.

At a meeting of the New York Farmers' Club, in answer to an inquiry about keeping poultry on a large scale, Warren Leland, of the Metropolitan Hotel, New York, who raises chickens at his Highland Farm in Westchester Co., said: "I have found that for every hundred fowls one must give up at least an acre, but rough land is as good as any. Hens naturally love the bush, and I lop young trees, but leave a shred by which they live a year or more. These form hiding places and retreats for them.

In such places they prefer to lay. I have great success, and it depends on three or four rules, by observing which I believe one can make a good living by hens and Turkeys.

1. I give my fowls great range; eighteen acres belong to them exclusively. Then the broods have a range of another large lot, and the Turkeys go half a mile or more from the house. The eighteen acres of poultry yard are rough land of little use for tillage. It has a pond in it and many rocks, bushes, weeds, sandy places, ash heaps, lime, bones, grass, and a place which I plough to give them worms.

2. When a hen hatches, I take her box, throw out the straw and earth, let it be out in the sun and rain a few days, and give it a good coat of whitewash on both sides. In the winter, when very cold, I have an old stove in their house and keep the temperature above freezing. There is also an open fire-place where I build a fire in cold wet days. They dry themselves, and when the fire goes out there is a bed of ashes for them to wallow in. Summer and winter my hens have all the lime, ashes, and sand they want.

3. Another reason why I have such luck is because my poultry yards receive all the scraps from the Metropolitan Hotel. Egg-making is no easy work, and hens will not do much of it without high feed. They need just what a man who works requires—wheat, bread, and meat. Even when wheat costs 2 dol., a bushel I believe in it for feeding hens. As to breeds I prefer the Brahmans, Light and Dark. I change the cocks every spring, and a man on the farm has no other duty than to take care of my poultry. I often have at one time three thousand spring chickens.

HINCKLEY POULTRY SHOW.

The general arrangement of both the poultry and the Pigeons, in Turner's exhibition pens, under a very capacious tent, was all that could be desired, but a little mismanagement in the prize schedule, by which both cockerels and pullets were entitled to separate premiums, though exhibited together in the same pen, caused considerable confusion. This plan, however, will be rectified at future meetings. Some very excellent *Dorkings*, both Grey and White, which competed in the general class, were to be met with at Hinckley. Of White *Cochins*, the whole were of the highest merit; in fact, very rarely, if ever, have such excellent pens of this breed been on view at any public exhibition, as those that were successful. The *Brahmas* were not nearly so good as they should have been, and the majority of the *Game* fowls were sadly out of feather. Some extraordinarily good *Sebrit* *Bantams* were shown; and the collection of *Pigeons* was throughout especially praiseworthy. The weather being very fine there was a large concourse of spectators, who expressed themselves in terms of high approval.

DORKING.—1, E. Wood, Clapton, Thrapstone. 2, J. Choyce, Atherstone. **C**. W. H. SALT, Leicester. *Chickens*.—Prizes. R. Wood (Pullets and Cockerel). C. J. Watts, King's Heath, Birmingham (Pullets and Cockerel). **S**PARTERS.—1, M. Brown, Ab Kettleby, Melton Mowbray. 2, and Prize, J. Stephens, Walsall (Cockerel and Pullets). **C**OCCHIN CHINA.—1, J. Stephens. 2, H. C. Woodcock, Bearsly, Leicester. *Chickens*.—1, J. Stephens (Cockerel and *he* Pullets). Prize, H. C. Woodcock (Pullets). **W**HITE.—1, H. E. Emberlin, Oadby, Leicester. 2, no competition. *Chickens*.—Prizes. A. Williamson, Queenborough Hall, Leicester (Pullets and Cockerel). *he*, H. E. Emberlin (2). **B**RAHMA POULTRY.—*Chickens*.—Prize, J. Watts (Cockerel). Prize, H. C. Woodcock (Pullets). **G**AME.—1, F. Handley, Loughborough. 2, W. E. Oakley, Atherstone. *c*, W. H. Clare, Atherstone. *Chickens*.—Prize, Mrs. Milhouse, Hinckley (Pullets). Prize, W. E. Oakley (Cockerel). *he*, W. H. Clare (Pullet); W. E. Oakley, Atherstone (2) (Pullet). **H**AMBERGERS.—*Golden-spangled*.—1, J. Stephens. 2, H. E. Emberlin. *Silver-spangled*.—1, J. Choyce, Atherstone. 2, F. Handley, Loughborough. **B**ANTAMS (*clean-legged, any variety*)—1 and *c*, W. Draycott & Sons, Humberstone. 2, J. Watts. *Game*.—1 and Prize, F. Handley. 2, J. Stephens. *he*, S. Deacon, jun., Gundle. **D**UCKS.—*Aylesbury*.—1, J. Choyce. 2, H. E. Emberlin. *he*, S. Deacon, jun.; J. Choyce. *Rouen*.—1, W. Choyce, Siledon, Atherstone. 2, J. Watts. *he*, R. Wood. **T**RUFFYS (ANY VARIETY)—1 and 2, W. H. Johnson. **G**EESE.—1, A. Guy, Eaton, Grantham. 2 and *he*, J. Choyce. **E**XTRA STOCK.—*he*, W. H. Jackson (Houlan Fowls and Buenos Ayrean Ducks).

PIGEONS.

CARRIERS.—1, J. Watts. 2, J. Stephens. **T**URBITS.—1, J. Stephens. 2, W. Choyce, Sibson. *he*, F. H. Paget, Birstall, Leicester. **P**OUTERS.—1 and 2, J. Stephens. *he*, H. E. Emberlin. **F**ANTAILS.—1, J. Stephens. 2, J. Watts. *he*, F. H. Paget; W. Choyce; H. E. Emberlin. **M**AGPIES.—1, J. Stephens. 2 and *c*, W. Draycott & Son. **A**NY OTHER VARIETY.—1, F. H. Paget. 2, J. Stephens. *he*, F. H. Paget; W. Choyce; J. Stephens; W. Draycott & Son; J. Watts (3). *c*, J. Choyce; W. Draycott & Son.

RABBITS.—*Hawest*.—1, Withheld. 2, W. H. Jackson, Lutterworth. *Greatest length of ears*.—1, W. H. Jackson. 2, M. Foxwell, Hinckley.

Mr. Hewitt, of Sparkbrook, near Birmingham, officiated as Judge.

HENS TRESPASSING.—The steeping of corn in whiskey to catch hens which trespass is no bad idea. It brought to my mind a circumstance which occurred in my early days. A farmer complained to Mr. Beecher that his crows did a great deal of harm, and requested compensation. Mr. Beecher told him to impound. The farmer got good strong porter, and steeped wheat and laid it for the crows. When they got drunk he tied their claws with twine, and carried along his line of crows to Mr. Beecher, who with his visitors enjoyed the fun

very much, and I must add that the farmer was liberally and generously rewarded.—(*Irish Farmers' Gazette*)

ECCLESHILL POULTRY SHOW.

This, the third annual Show of the Ecclehill Society, was held on the 3rd inst., and in spite of all the difficulties against which the Committee had to contend, notably the want of time in which to obtain subscriptions and get up the Show, it was in almost all respects a complete success. The prize list for poultry had been remodelled, and instead of divisions for old and young poultry the two were thrown together, the prizes consequently doubled, and some additional classes made. The Pigeon prizes were also increased, and a cup given for the largest number of points brought some strong entries. The pens were on Turner's principle, and all the arrangements were very good. The stock shown both in the poultry and Pigeon classes was excellent in quality and good in numbers. More especially may this be said of the Pigeons, in which one class, Antwerps, consisted of no less than twenty-three entries, most of them of great merit.

GAME.—*Black-breasted and other Reds*.—Cup, E. Aykroyd, Ecclehill. 2, J. Hodgson, Bradford. *he*, W. Johnson, Idle. *Any other variety*.—1, E. Aykroyd. 2, H. C. & W. J. Mason, Drighlington. *he*, J. W. Thornton, Bradford. *Hen or Pullet*.—1, J. Preston, Alerton. 2, J. Jackson, Ecclehill. *he*, J. Hodgson; E. Aykroyd; J. Firth, Chatsworth. **S**PANISH (Black).—1, H. Beldon, Bingley. 2, J. Thresh, Bradford. **D**ORKINGS.—1 and 2, J. Stott, Healey. **C**OCCHIN CHINA.—1, H. Beldon. 2, E. Baxter. **B**RAHMA POULTRY.—1, J. Bailey, Earby. 2, H. Andrews. *he*, H. Beldon; M. Scott, Cote, Idle. **H**AMBERGERS.—*Silver-spangled*.—Cup, H. Beldon. 2, H. Pickles, jun., Earby. *he*, W. Bairstow. *Golden-spangled*.—1, H. Beldon. 2, J. Rollinson, Lindley. *he*, C. Holstead, Fearncliffe. *Silver-pencilled*.—1 and *he*, H. Pickles, jun. 2 and *c*, H. Beldon. *Golden-pencilled*.—1, J. Smith, Gilsted. 2, H. Beldon. *he*, J. Hough. **B**LACK.—1, H. Beldon. 2, H. W. Hingworth, Idle. *he*, H. Pickles, Jun., Alerton. **A**NY OTHER VARIETY.—1 and *he*, H. Beldon. 2, H. Beldon, Clayton. **G**AME BANTAMS.—*Brown Red*.—1, Steele, Halifax. 2, W. Entwistle, Westfield, Cleckheaton. *Any other Variety*.—1, J. Thornton, Idle. 2, Steele. **B**ANTAMS.—*Any other Variety*.—1, J. Waddington, Guseley. 2, H. Beldon. *he*, H. W. Hingworth. —Steele. *c*, W. Greaves, Bradford. **S**ELLING CLASS.—1, J. Thresh. 2, W. Johnson. *he*, H. Bealand; M. Scott; H. Beldon. **D**UCKS.—*Aylesbury and Rouen*.—2, J. Ward, Drighlington. *Any other Variety*.—2, A. Vint, Idle (Muscovy).

PIGEONS.

CARRIERS.—1, E. Horner. 2, H. Yardley, Birmingham. *he*, H. Yardley; E. Horner. **P**OUTERS OR CROPPERS.—1, E. Horner. 2, J. Hawley. *he*, J. Hawley; E. Horner; Robinson & Glen. **T**EMPLETS.—1 and 2, J. Hawley. *he*, H. Yardley (2). **O**WLS.—1, H. Yardley. 2 and *c*, J. Hawley. *he*, H. Yardley; W. Stanhope, Ecclehill. **T**URBITS.—1 and 2, W. Lund, Shipley. 2 and *he*, E. Horner. **A**NTWERPS.—1, J. Jackson. 2 and *c*, S. Smith, Idle. *he*, J. Hawley; W. S. Ingle; J. Chadwick, Windhill; A. Child, Apperley Bridge; W. Stanhope; W. Hall, Undercliffe; E. Horner; W. H. Mitchell, Moseley, Birmingham. **D**RACOONS.—1, W. Lund. 2, H. Yardley, Birmingham. *he*, J. Hawley; H. Yardley; C. Jowett, Idle; J. A. Collinson, Halifax; E. Horner. **F**ANTAILS.—1, H. Yardley. 2, E. Horner. *he*, J. Hawley; E. Horner. **J**ACOBS.—1 and 2, J. Hawley. *he*, E. Horner. **A**NY OTHER VARIETY.—1, J. Thresh, Bradford. 2, J. Cannan, Bradford. *he*, H. Yardley; S. Smith; E. Horner (2); Robinson & Glen. *c*, J. Jackson. **S**ELLING CLASS.—1, J. Hawley. 2, W. Lund. *he*, W. Stanhope; W. Lund; E. Horner. *c*, S. Smith.

RABBITS.—*Long eared*.—Point Cup, J. Hawley. 1, C. Dibb. 2, W. Ridd, Undercliffe. *Any other Variety*.—1, Master J. Hartley, Bowing. 2 and *he*, F. Monson.

JUDGES.—*Poultry, Pigeons, and Rabbits*: Mr. J. Thompson, South-oram; Mr. E. Smith, Middleton.

LEYBURN POULTRY SHOW.

This was held in connection with the Richmondshire Agricultural Society's Show, on the 7th inst. The following awards were made by the Judge, Mr. James Dixon, North Park, Clayton, Bradford.

GAME.—*Black-breast or other Reds*.—1 and 2, W. Bearpark, Ainderby Steeple. *Any other Variety*.—1, C. Oiler, Leyburn. 2, W. Bearpark. **D**ORKING.—*Any Variety*.—1, W. Bearpark. 2, Mrs. B. Pierson, Bedale Hall. **S**PANISH.—*Black*.—1, W. Bearpark. 2, Rev. J. G. Milner, Bellerby. **C**OCCHIN CHINA.—1 and 2, Rev. J. Robertson, Swinton. **P**OLISH.—1, W. Bearpark. 2, G. Wood, Hamburghs. *Golden-spangled*.—1, W. Bearpark. *Silver-spangled*.—1, Rev. J. G. Milner. *Golden-pencilled*.—1, W. Bearpark. 2, Miss B. Pierson. *Silver-pencilled*.—1, W. Bearpark. 2, Miss B. Pierson. **B**ANTAMS.—1, G. Carter, Bedale. 2, Rev. J. Robertson. **D**UCKS.—*Rouen*.—1 and *c*, Rev. J. G. Milner. 2 and *he*, Rev. J. Robertson. *Aylesbury*.—1, Rev. J. Robertson. 2, M. Richardson, Constable, Burton. *Any other Variety*.—1 and 2, Rev. J. G. Milner. **G**EESE.—1, M. Robinson

MORPETH POULTRY SHOW.

This was held on the 8th inst., and was decidedly an improvement upon last year's show, both as regards quality and the number of specimens exhibited. The *Game* fowls were very good, but the adults were mostly out of feather. The prize *Brahmas* were in full feather, and very nearly won the cup, which went to a very fine pen of *Spanish* in excellent condition; a pair of very promising chickens were shown in this class. *Hambergs* were very good considering the season. *Bantams* were of fine quality, especially the first-prize Black Red *Game* cockerel and pullet. *Ducks* were well shown, first-class Black East Indian ducklings winning in the "Variety class." The first prize in the Selling class was won by a grand pair of Brown Red *Game* chickens, which were soon claimed at the selling price, £1. In several of the classes birds of this year's hatching competed successfully with all others.

GAME.—*Black-breasted and other Reds*.—1, J. B. H. Steekbarn. 2, Nichol and Lindsay, Morpeth. *he*, G. Taylor, Steekbarn. *Any other Variety*.—1, G. Taylor. 2, Nichol & Lindsay. **C**OCK.—1, J. Robson, Belside. 2, Nichol & Lindsay. **C**OCCHIN CHINA (ANY VARIETY).—2, J. Woods, Netherburn. **B**RAHMA.—1 and 2, J. Stalker. **S**PANISH.—Cup, Gibson & Stalker, Woodhorn. 2 and *he*, Sanderson & Oliver. **H**AMBERGERS.—*Golden-spangled*.—1 and *he*, G. & W. Johnson, Choppington. 2, A. Tait, Morpeth. *Silver-spangled*.—1, C. Anstron,

Beidsie, 2. Stephenson & Cheyne, Cowpen Lane. *hc, G. & W. Johnson Gold or Silver-pencilled*.—1, R. Bell, 2. Master J. W. Schofield, Morpeth. *hc, Stephenson & Cheyne. ANY OTHER VARIETY EXCEPT BANTAMS*.—1, J. Brown and Co., Sunderland. 2, M. Byder, Monkwearmouth. **BANTAMS**.—*Game Black*.—1, *W. or of Red*.—1, 2. D. Dowdy, Sleekburn. *Game, Any other Variety*.—1 and 2. J. Ferry, Cowpen. *Any other Variety except Game*.—1, R. Lashley, Sleekburn. 2, Miss F. Wilson, Woodhorn Manor. **DUCKS**.—*Aylesbury*. 1, Miss F. Wilson. 2, J. O'Leary, Morpeth. *Rouen*.—1, Miss F. Wilson. 2, Miss Wilson. *hc, Miss Davie, Hepscott Red House. Any other Variety*.—1, Miss Schofield, Morpeth (Buenos Ayres). 2, Mrs. J. Salkeld, Bramwell (Buenos Ayres). *hc, Miss A. Wilson (Call). SELLING CLASS*.—1, J. Ball, 2. C. Armstrong. *hc, Spheniscus, Morpeth (various). Nqr FOR COMPETITION*.—*hc, F. E. Schofield, Morpeth (Buenos Ayres).*

JUDGE.—Mr. John Shorthose, Hartford Bridge, Cramlington.

CLEVELAND AGRICULTURAL SOCIETY'S SHOW.

THE Show of the Cleveland Agricultural Society was this year held at Guisborough, on the 8th inst. The railway communication is not of the most complete kind, and, in addition, the district is not densely populated; there were, consequently, fewer visitors than usually attend this Society's Show. It was held in Admiral Chaloner's grounds, in a most picturesque locality in front of the Priory, and shielded by woodlands on three sides, and by a hill on the fourth. A large marquee was devoted to the poultry, of which the classes were not numerous, but the entries were good.

Spanish were but poor, the *Dorkings* of good quality, and the *White Cochins* in the first-prize pen of extraordinary merit, although the Buifs were bad, and the Partridge and *Brahmas* but moderate. The first-prize *Red Game* were Black Reds of excellent style and form, and very close in flesh; and the second good Brown Red chickens. The *Duckings* were bad, but the single cocks compensated for them, a cockerel of good proportions gaining first honours. The *Bantams* were bad, but the winning-pens in all the *Hamborough* classes were first-rate; and in the "Variety class" was an extremely good pair of *Houdan* chickens. The *Aylesbury Ducks* were very good in beak, as also the *Rouens*, and the latter were also very large; and in the next class for *Ducks*, *Black East Indian*, splendid in plumage, were first, and domesticated *Wild Ducks* second. It is seldom we have seen such a display of *Geese*, both *Geese* and *goslings* being of remarkable size of frame and very good in plumage; of *Turkeys* there were some very large birds, and we noticed a great improvement in the size of the *Turkey* points, as compared with those shown last year.

There were not many *Rabbits*, but those shown were good.

SPANISH (Black).—1, W. G. Fardon, Driffield. 2, W. Bearpark, Ainderby Steeple, Northallerton. **DORKINGS**.—1, W. Bearpark. 2, O. A. Young, Driffield. **COCHINS** (White or Cream).—1, G. H. Proctor, Durham. 2, J. H. Brantwhite, Stockton-on-Tees. **WHITES**.—1, G. H. Proctor. 2, and *hc, G. H. Brantwhite, Northallerton. Partridge or Grouse*.—1, W. J. Stewart, Darlington. **BRAMA POOTRA**.—1, E. Corney, Whitby. 2, W. G. Fardon. **GAME**.—*Black-breasted or other Red*.—1, E. Aykroyd, Eecleshill. 2, W. Bearpark. *hc, P. Starry, Ormsby, Middlesbrough; T. Blackburn, jun., Great Brompton (2). Any other Variety*.—1, E. Aykroyd. 2, W. Bearpark. *Cock*.—1, T. Blackburn, jun. 2, J. Watson. *hc, E. Aykroyd; W. Gately, Hemlington. GAME BANTAMS*.—1, W. J. Stewart (Call). 2, E. Corney. 3, T. Blackburn, jun. **HAMBOROUGHS**.—*Golden-pencilled*.—1, W. Bearpark. 2, G. Holmes, Great Driffield. 3, R. A. White, Whitby. 3. *Burn, Whitby. Silver-pencilled*.—1, G. Holmes. 2, W. Bearpark. *Golden-spangled*.—1, W. G. Fardon. 2, G. Pounder, Kirby Moorside. *hc, G. Holmes. c, O. A. Young. Silvers-spangled*.—1, J. Best, Boroughbridge. 2, G. Holmes. **ANY OTHER VARIETY**.—1, Rev. J. G. Milner, Ellerby Vicarage, Leaburn. 2, W. Bearpark. **CROSS BRED**.—1, Mrs. Buffham, Saltburn-by-the-Sea. 2, J. W. Pease, Hutton Hall. *hc, G. Pounder. Deeds*.—1, W. G. Fardon. 2, T. Blackburn, jun. **HAUNTONS**.—1, O. A. Young. *Rouen*.—1 and 2, Rev. J. G. Milner. *hc, G. Pounder. Any other Variety*.—1, S. Barn, Whitby (Black East Indian). *hc, Rev. J. G. Milner. GESE*.—1, Rev. G. Hustler, Stillingfleet, York. 2, O. A. Young. *c, J. Storry. Stokesley; Mrs. Braithwaite, Stokesley. Goslings*.—1, Rev. G. Hustler. 2, J. Storry. *c, Mrs. Braithwaite. TURKEYS*.—1, J. Storry. 2, Mrs. Braithwaite. *hc, Rev. G. Hustler; G. Holmes. Point*.—1, Mrs. Buffham. 2, Mrs. Ward. *Black*.—1, W. G. Fardon. 2, O. A. Young. *hc, M. Harrison; Mrs. Reardon, Skutumpah Farm; J. Storry.*

RABBITS.—*Levath of Ear*.—1, T. Bousley, Egglecliffe, Yarm (Lop-eared). *Hearted*.—1, O. A. Young. *Fancy Bred*.—1, E. Bensley (Himalayas). 2, W. Elocote, Guisborough. *hc, J. Mudd, Newport, Middlesbrough.*

JUDGE.—Mr. E. Hutton, Pudsey, Leeds.

LEIGH POULTRY SHOW.

This Show was held on August 31st. The awards were as follow:—

GAME.—*Black-breasted Red*.—1, C. Chaloner, Whitwell, Chesterfield. 2, C. W. Brierley, Middleton. *Brown-breasted Red*.—1, C. W. Brierley. 1, T. Statter, jun. *Staud Hill, Whitefield. c, C. Chaloner. Any other Variety*.—1, C. Chaloner. 2, C. W. Brierley. **SPANISH** (Black).—1, C. W. Brierley. 2, N. Cook, Choumont. **CROSS-BRED**.—1 and 2, W. A. Taylor, Manchester. *hc, T. Pringle, Newcastle-on-Tyne. Any other Colour*.—1, J. Siebel, Timperley, Cheshire (White). 2 and *hc, W. A. Taylor. BRAHMA POOTRAS*.—1, J. H. Pickles, Birkdale, Southport. 2, W. A. Taylor. *hc, E. Leech, Rochdale. DORKINGS*.—1, J. H. Pickles, jun. (Silver). 2, C. W. Brierley. 3, W. A. Taylor. *hc, E. Leech, Rochdale. Partridge or Grouse*.—1, J. H. Pickles, jun. 2, T. Wrigley, Skipton. **HAMBOROUGHS**.—*Golden-pencilled*.—1, J. H. Pickles, jun. 2, T. Wrigley, jun. *Middleton. hc, H. Pickles, jun. c, S. Smith, Northwam, Halifax. Silver-pencilled*.—1 and 2, H. Pickles, jun. *Golden-spangled*.—1 and *hc, H. Pickles, jun. 2, D. Lord, Staekstead. c, N. Martin, Denton, near Manchester. Silvers-spangled*.—1, Cup and *hc, D. Lord. 1 and 2, H. Pickles, jun. Black*.—1, N. Cook. 2, N. Martin. **POLANDS** (Any variety).—1 and 2, H. Pickles, jun. (Silver). *hc, P. Unsworth, Loughton (2). c, W. Fearnley, Loughton (Silver). FRENCH FOWLS*.—1, J. H. Stott, Rochdale. 2, N. Cook. **BANTAMS**.—*Game*.—1, G. Auderton, Acornington (Black Red). 2, P. West, Abram. *hc, N. Cook. Any other Variety*.—1, J. H. Pickles. 2, S. & R. Ashton, Mottram (Black). *hc, N. Cook; J. Watts, King's Heath, Birmingham. ANY OTHER VARIETY*.—1 and 2, N. Cook, Bantams. **DUCKS**.—*Aylesbury*.—1, E. Leech. 2, J. H. Stott. *Rouen*.—1, Cup. 2, Gladstone, jun., Court Hoy, Liverpool. 1, J. Scotson, Little Eyreton. 2, Gannon, Chester. *hc, E. Leech; J. Scotson; T. Wakefield, Goolborne, Newton-on-Willows. Any other Variety*.—1, C. W. Brierley. 2, D. and W. Barton (Shell). *hc, R. & W. Barton (Call); J. Kilshall, Atherton Hall*

(Red-neck Divers); C. W. Brierley. **GESE**.—1 and 2, E. Leech. **TURKEYS**.—1, E. Leech. 2, J. Bent, Bradshawleach, Pennington. **SELLING CLASS**.—1, N. Cook. 2, W. A. Turner. 3, C. W. Brierley. *hc, P. Unsworth (Polands). 2. c, T. Wakefield, Loughton. EXTRA SROCK*.—*hc, N. Cook (Pheasants). hc, Miss A. Cook (Rabbit).*

SINGLE BIRDS.

GAME (any variety).—*Cock*.—1, J. Wood, Wigan. 2, J. Holland, Manchester. *hc, C. Chaloner. c, R. Southern, Leigh. Hen*.—1, T. Statter, jun. 2, C. W. Brierley. *hc, C. Chaloner. Cockerel*.—1, C. Chaloner. 2, J. Mason, St. John's Worcester. *hc, C. W. Brierley; J. & W. Wallas, Heaton. Pullet*.—1, C. W. Brierley. 2, J. Holland. *hc, W. Scotson, Bickershaw, Abram; J. Horne, Mouldon, Warrington (Brown Red); C. Chaloner. BANTAM* (any variety).—*Cock or Cockerel*.—1 and 2, A. Smith, Westleigh (Cockerels).

PIGEONS.

TROUBLERS.—1, J. Hawley, Bingley, Yorkshire. 2, F. Moore, Burnley. **CARRIERS**.—1, D. Bromiley, Over Hulton. 2, H. Yardley, Birmingham. *hc, W. Markland, Deane, Bolton. PICTURES*.—1, J. Hawley. 2, W. Gannon. **BARBS**.—1, H. Yardley. 2, D. Bromiley. **OVALS** (any variety).—1, D. Bromiley. 2, J. Hawley. **DRAGONS**.—1 and 2, J. Holland. *hc, D. Bromiley. hc, P. Unsworth; W. Markland. TROMPETERS*.—1, J. Hawley. 2, P. Unsworth. **FANTAILS**.—1, J. Hawley. 2, D. Bromiley. *hc, J. Kemp, Bolton. ANY OTHER VARIETY*.—1, J. Hawley. 2, J. Watts. *hc, H. Yardley. SELLING CLASS*.—1, J. Hawley. 2, J. Watts.

JUDGES.—*Poultry*: Mr. R. Teebay, Fulwood, Preston. *Pigeons*: Mr. Kidpath, Handforth Hall, near Willmslow, Cheshire.

TODMORDEN POULTRY SHOW.

THIS was held on the 10th inst. The birds were numerous and of first-class quality. The pens including old and young birds made it a difficult task for the Judge.

GAME.—1, C. W. Brierley, Middleton. 2, E. Aykroyd, Leeds. *Cock*.—1, C. W. Brierley. 2, F. Aykroyd. *Hen*.—1, B. Consterdine, Littleborough. 2, C. W. Brierley. **BANTAMS**.—1, J. H. Pickles, Birkdale, Southport. 2, F. Leech, Borchard, Cuckfield, Sussex. 3, T. H. Greenwood, Todmorden. 4, J. White, Wakefield. **BANTAMS**.—1, J. W. Morris, Rochdale (Silver-pencilled). 2, J. H. Pickles, Jaramose, *hc, S. & R. Ashton, Mottram. Game*.—1 and *hc, W. F. Entwistle, Cleekeath, 2, J. W. Morris, Rochdale. hc, Beilingham & Gill, Burnley. c, T. Baker, Burnley. DORKINGS*.—1, H. Pickles, jun. Early. 2 and *hc, J. Stott, Rochdale. SPANISH*.—1, W. Sutcliffe, Todmorden. 2, C. W. Brierley. **HAMBOROUGHS**.—*Golden-pencilled*.—1, H. Pickles, jun. 2 and *hc, T. Wrigley, jun. Middleton. Golden-spangled*.—1 and 2, H. Pickles, jun. *Silvers-spangled*.—1, H. Pickles, jun. 2, H. Pickles, jun. *Silver-pencilled*.—1 and 2, H. Pickles, jun. *Black*.—1, P. Lord. **ANY OTHER VARIETY**.—1 and 2, H. Pickles, jun. **SELLING CLASS**.—1, H. Pickles, jun. 2, S. Lord, Healey Hall Bottom, Rochdale. *c, T. Barker, Burnley. GESE*.—1, E. Leech, Rochdale. 2, S. H. Stott. **DUCKS**.—*Aylesbury*.—1, E. Leech. 2, S. H. Stott. *Buenos*.—1, E. Leech. 2, A. West, Worthorne, Burnley. *hc, S. H. Stott. Any other Variety*.—1, T. C. Harrison, Hull. 2, S. & R. Ashton. **TURKEYS**.—1, E. Leech. 2, J. Sykes, Shroctat, Halifax.

Mr. Robert Payne, of Brierfield, Burnley, is the Judge.

COTTINGHAM POULTRY SHOW.

COTTINGHAM, one of the most beautiful villages of the East Riding of Yorkshire, held its poultry Show on the 9th inst., in a small but well-wooded park. The entries were numerous, and in some of the classes the birds were good. The *Spanish* were exceedingly fine, especially the first-prize pen, but the *Cochins* and *Dackings* were only of moderate quality. The first-prize *Red Game* were Brown, and the second *Black Red*. The former were out of condition to some extent, but the hen in the latter pen was bad in colour of plumage and eye. *Dackings* were first in the Variety class, and the extra prize for the best pen was awarded them. The *Pullets* were uncommonly fine, *Silvers* being first and *Blacks* second; and the first-prize *Silver cock* was also extremely good. The *Hamboroughs* were of moderate quality, and the entries good; and in the class for *Farmyard crosses* there were some remarkably heavy birds. In the *Selling* class an unusually good pen of *Spanish* was shown, and quickly appropriated, the cock being superior to the first prize bird in the *Spanish* class. The *Bantams* were all exceedingly good, with the exception of the *Game*, which were very poor. There were some large-framed *Geese* and excellent *Ducks*.

The competition with *Pigeons* was keen in all classes, and the quality much finer than we expected to find. The first-prize *Pouters* were *White*, very good in thigh and feather. The second prize went to *Reds*. The *Carriers*, though a little coarse, were very long and well developed. The first prize *Turbits* were *Blue*, and the second *Red*. No class contained birds of higher quality than the *Dragoons*, though some were rather old for the show pen. The *Atmonds* shown by Mr. Adams were an exquisite pair in all points, and an exceedingly good match in colour and marking; the *Nuns* were also very good. In the "Variety class" *White Owls* were first, and *Black Magpies* second. The *Rabbits* made but a moderate display. For the small amount awarded to *Cage Birds* there was a capital entry. The two winning birds in the first class were *Belgians*, and in the next the first was a handsome light *Goldfinch Mule*, and the second a *Marked Canary*; and the winner of the new cage was a good *Jonque Lizard*, though rather flecked with white.

SPANISH.—1, T. C. & E. Newbitt. 2, W. G. Pinder, Driffield. *hc, J. Williamson, Cuck*.—1, G. Holmes. **DORKINGS**.—1, G. Holmes. 2, J. White. *Cock*.—1, J. Thompson. **COCHINS**.—1, F. Dawson, Beverly. *hc, Taylor; J. Dawson, Cuck*.—1, E. Cook. **GAME**.—*Red*.—1, G. Holmes. 2, W. Boyes. *Cock*.—1, W. G. Pinder. *hc, W. Boyes. Any other Variety*.—1, 2, and *hc, W. Boyes. hc, Mrs. Allans. Cock*.—1, W. Boyes. **POLANDS**.—1 and 2, Mrs. Proctor, Hull. *Cock*.—1, Mrs. Proctor. **HAMBOROUGHS**.—*Golden-spangled*.—1, G. Pinder. 2, Marnock. *Cock*.—1, G. Holmes. *Golden-pencilled*.—1, Chatter, Driffield. 2, G. Holmes. *Cock*.—1, G. Holmes. *Silvers-pencilled*.—1, G. Holmes. 2, Holly, Hull. *Cock*.—1, G. Pinder. *Silvers-pencilled*.—1, G. Liveridge. 2, G. Holmes. *hc, C. A. Harrison. Cock*.—1, G. Holmes. **FARMYARD CLASS**.—1, C. Goodby. 2, C. Hare, Cuck. 3, C. Goodby. **SELLING CLASS**.—1, T. and E. Newbitt. 2, T. C. Harrison. *hc, Lott; G. Holmes; C. Riley. Cock*.—

1,—Hague, Newland. *hc*, T. C. Harrison, Hull. VARIETY CLASS.—1,—Loft, 2.—Vawse. *hc*, T. C. Harrison; —Loft. BANTAMS.—*Gold-laced*.—1 and 2, T. C. Harrison. *Cock*.—1, T. C. Harrison. *Gamer*.—1,—Hardy, Hestle. 2.—R. W. Beverley. *hc*, H. Adams, Beverley. *hc*, C. Wilson, Driffield. *Cock*.—1,—Bingrose. *Any other variety*.—1 and *hc*, T. C. Harrison. 2, Messrs. Newhall. SPECIAL PRIZES.—1, G. Bromley. 2.—Chapoy. *hc*.—Loft. GREENS.—1, J. Harrison. 2, J. Jordan. DUCKS.—*Aylesbury*.—1 and 2, O. A. Young. *hc*.—Lawson. *Any other variety*.—1, Richardson. 2 and 3, T. C. Harrison. TURKEYS.—1, G. Holmes. 2.—Jordan.

PIGEONS.

POUTERS.—1, H. Adams. 2, G. Statter. CARRIERS.—1,—Campey, Beverley. 2, H. Yardley. TERRITS.—1,—Lawson. 2.—Richardson. *hc*, Whole class. TRUMPETERS.—1,—Marshall. 2.—Gillins. JACOBS.—1,—Sandors. 2, G. Statter. FANTAILS.—1, Davis & Thompson. 2, H. Yardley. TUMBLERS.—1 and 2, H. Adams. *hc*, H. Yardley. BARNS.—1,—Lawson. 2.—Richardson. NEWS.—1, T. Statter. 2.—Richardson. *hc*, H. Yardley; Davis & Thompson. ANY OTHER VARIETY.—1, H. Adams. 2 and *hc*, Mrs. Proctor, Hull.

CANARIES.—1, Miss Ellison. 2, G. Grant. *hc*, R. Redhead; —Lewis; —Petch. *Any other variety*.—1 and *hc*, —Petch. 2, R. Redhead. *For New Cage*.—1, G. Lewis, Hull. *hc*, C. Weddall.

RABBITS.—*Lop-eared*.—*Black*.—1,—Ashton, Hull. 2.—Turner, Hull. *Doc*.—1 and 2.—Ashton. *Any other variety*.—1,—Ashton. 2.—Lunn.

JUDGE.—Mr. E. Hutton, Pudsey, Leeds.

GREAT HORTON POULTRY SHOW.

THERE is scarcely a village in the West Riding of Yorkshire that has not its annual Poultry and Pigeon Show, and following the example of their neighbours, a few of the amateurs of this district brought together on the 10th inst. an excellent exhibition of stock, which was inspected by a great number of visitors. The *Gam*, with the exception of the first-prize Black Reds, were of poor quality. The *Hamburghs* were moderately good, and the *Polands* very fine; but the best class in the Show was the *Gamm Bantam*. In *Ducks*, the first prize was taken by Ruddy Shell, and the second by Rouens.

The *Pigeons* were tolerably numerous, and there were some good birds in all classes, although several pens of birds were disqualified; in the Antwerp class, for instance, two cocks were exhibited as a pair.

The entries of *Cage Birds* were not numerous, but there were some very fine specimens, notably of Norwich Canaries. The *Evenly Marked* were also very good, also the *Jonque Lizard*; the *Meales* were poor. We noticed a most handsome *Pied-bald Linnct Mule*, winner of the first prize for that variety, and both *Buff* and *Yellow Goldfinch Mules* were worthy of notice.

GAME.—*Cock*.—1, G. Naylor, Great Horton. 2, E. Jowett, Great Horton. *hc*, J. Hodgson, Bowling. *Any Variety besides Game*.—*Cock*.—1, H. Barker, Keighley. 2, J. Thresh, Bradford. *Black-breasted or other Bids*.—1, J. Preston, Alerton. 2, E. Jowett. *hc*, J. Hodgson. *Any other variety*.—1, G. Ambley, Queensbury. 2, J. Preston. HAMBURGS.—*Gold-spangled*.—1, J. Preston. 2, H. Bowker, Keighley. *Silver-spangled*.—1, H. Bowker. 2, T. Robinson, Harden. *hc*, T. Fawcett, Baildon; W. Bairdow, Bingley. *Gold-pencilled*.—1, J. Preston. 2, F. Steel, Halifax. *hc*, Clough & Jackson, Lister Hills. *Silver-pencilled*.—1, H. Bowker. 2, J. Preston. *Black*.—1, H. W. Illingworth, Idle. 2, T. Robinson. *hc*, Clough & Jackson. SPANISH (Black).—1 and 2, J. Thresh. CUCKINS-CHINAS.—1, J. Preston. 2, J. Dixon, Horton. *hc*, J. Rudd, Horton. DORINGS.—1, J. Preston. ANY OTHER VARIETY.—1, H. Bowker. 2, J. Preston. GAME BANTAMS.—*Any Variety*.—1, F. Steel. 2, J. Blamires. *hc*, F. Steel; J. Blamires; E. K. Fox, Great Horton (2). BANTAMS.—*Any other Variety*.—1, H. W. Illingworth. 2, J. Hodgson. *DIVERS*.—*Any Variety*.—1 and 2, J. Dixon, Horton. *hc*, Miss Bentley; H. Flather, Bowling.

PIGEONS.

CARRIERS.—1, H. Snowden, Horton. 2, J. Holden, Wibsey. CROPPERS.—1, J. Hawley, Bingley. 2, H. Snowden. *hc*, W. Whitaker, Horton. TEMPLETS.—1, J. Hawley. 2, Clayton & Barstow, Gillingham. JACOBS.—1, J. Hawley. 2, Clayton & Barstow. *hc*, J. Thompson, Bingley. BARNS.—1, J. Thresh. 2, J. Hawley, Bingley. *hc*, Clayton & Barstow. FANTAILS.—1, J. Hawley. 2, Clayton & Barstow. *hc*, J. Thompson. DRAGONS.—1, J. Holden. 2, Clayton & Barstow. *hc*, E. Jowett; Clayton & Barstow. TERRITS.—1 and 2, Clayton & Barstow. *hc*, J. Thompson. ANTWERPS.—1, Clayton & Barstow. 2, F. Steel. ANY OTHER VARIETY. 1, J. Hawley. 2, Clayton & Barstow. *hc*, H. Snowden; S. Heyworth, Dikirkh; M. Smith, Horton; J. Thompson; J. Thresh.

CAGE BIRDS.

NORWICH.—*Yellow*.—1 and 2, W. Heap, Bradford. *Clear Buff*.—1, W. Heap. 2, J. Wilkinson. *GREENS*.—*Clear Yellow*.—1, J. Wilkinson. 2, W. Heap. *Clear Buff*.—1, J. Wilkinson. 2, W. Heap. *Evenly-marked Yellow*.—1, S. Burton, Middlesbrough. 2, W. Heap, Bradford. *Evenly-marked Buff*.—1, J. Wilkinson. 2, S. Burton. LIZARDS.—*Yellow*.—1, R. Hotman. 2, J. Wilkinson. *Buff*.—1 and 2, J. Wilkinson. YORKSHIRE.—*Yellow*.—1, J. Wilkinson. 2, W. Heap. *Buff*.—1, J. Wilkinson. 2, M. Holroyd, Horton. ANY VARIETY.—1, J. Wilkinson. 2, J. Crossley, Great Horton. GOLDFINCH MULES.—*Evenly-marked Yellow*.—1 and 2, W. Heap. *Evenly-marked Buff*.—1, T. Hawman, Middlesbrough. 2, W. Heap. LINNET MULE.—1, W. Heap. 2, W. & C. Burniston, Middlesbrough.

RABBITS (Any Variety).—1, J. Evans, Queensbury. 2, F. Moulson, Little Horton. *hc*, H. Pool, Bradford.

JUDGES.—*Poultry and Pigeons*: Mr. E. Hutton, Pudsey, Leeds; and Mr. W. Cannan, Bradford. *Canaries*: Mr. James Taylor, Middlesbrough.

(From a Correspondent.)

THERE was not a large entry of birds, which I attribute to the Show not being properly advertised and its being the first attempt. Norwich Canaries were not so good as they are at some shows; the Belgians were very good, and will make a mark at any place they may go to. The competition of *Evenly-marked birds* was very close, and some of the best birds in the country were exhibited. Lizards were not up to the standard, except the first-prize Golden, and it was very evident that its journey had done it much harm, as it could not fairly draw itself together the whole day. Great credit is due to the Committee for the interest they took in this bird to bring it round; and should they have another show at Horton I would advise exhibitors to send them good entries, for I never saw birds better attended to. The *Yellow*

Yorkshire Canaries were noble, likewise the *Buff Yorkshire*. *Evenly-marked Goldfinch Males* were very good, and the prizes went to birds of no ordinary merit. *Linnet Mules* were only inferior specimens.

WHITBY CANARY SHOW.

This was held in the Congress Hall, Whitby, on the 13th inst. The following is the prize list, but we must defer further remarks till next week:—

NORWICH.—*Yellow*.—1, T. Irons, Northampton. 2, W. Barwell, Northampton. 3, J. Baines, York. *hc*, C. Burton, York; G. Gayton, Northampton. *Buff*.—1, R. Simpson, Whitby. 2, J. Adams. 3, T. Irons. *hc*, Moore & Wynne. *Evenly-marked Yellow*.—1, Moore & Wynne. 2, Adams. 3, J. Baines. *Evenly-marked Buff*.—1, J. Bexson. 2, G. Gayton. 3, T. Irons. *hc*, Moore and Wynne; J. Adams; W. Barwell. *Uncolorably-marked Yellow*.—1, J. Adams. 2, T. Irons. 3, C. Yeoman. *Uncolorably-marked Buff*.—1, Moore & Wynne. 2, W. Barwell. 3, T. Wales. *Green, Grey, or Buff-crested Yellow*.—1, T. Irons. 2, J. Bexson. 3, Moore & Wynne. *Green, Grey, or Buff-crested Buff*.—1 and 2, T. Irons. 3, J. Bexson. *hc*, W. Barwell; T. Irons. BURGUNDY.—*Yellow*.—1, J. N. Harrison. 2, T. Wales. 3, W. Bulmer. *Buff*.—1, W. Bulmer. 2, J. Bexson. 3, J. Barrett, Yorksire. *Yellow*.—1, T. Waindy, Norton. 2, Mrs. J. Wilkinson. *Whitby*.—1, C. Burton. *Buff*.—1, A. Webster. 2, Fairclough & Howe. 3, W. & C. Burniston. CRANVON.—*Yellow*.—1, T. Irons. 2, J. Bexson. 3, W. Bulmer. *Buff*.—1 and 2, T. Irons. 3, J. Bexson. LIZARD.—*Gold-spangled*.—1, J. Taylor. 2, J. N. Harrison. *hc*, J. Baines. *Silver-spangled*.—1, J. Baines. 2, J. N. Harrison. *hc*, T. Wales; J. Baines. CANARY.—*Green*.—1, G. Atkinson. 2, C. Burton. *hc*, Fairclough & Howe. BEEF.—1870.—1, R. Simpson. 2, Moore & Wynne. 3, R. Collinson. ANY OTHER VARIETY.—1, A. Webster. 2 and 3, M. Burton. GOLDFINCH MULE.—*Buff Marked*.—1, W. Handel. 2, C. Burton. 3, R. Hawman. *Dark*.—1, C. Burton. 2, J. Gray, Whitby.

PARROT.—1, Mrs. J. Wilkinson. 2, Mrs. J. Weighill.

LOCAL CLASSES.

NORWICH.—*Yellow or Buff*.—1, R. Simpson. 2, Mrs. J. McLaughlin & Brown. 3, H. Dale. *Yellow or Buff Marked*.—1 and 2, Mrs. J. Wilkinson. 3, T. Stewart. CANARY (Any other variety).—1, Mrs. J. Weighill (Clear Buff). 2, W. Henderson, Whitby (Crested Norwich). 3, M. Taylor (Cranvonn). MULE.—1, R. Corner, Whitby. 2 and 3, J. Gray.

BURGUNDY.—1, J. J. Haw. 2, W. Porritt. GOLDFINCH.—1, H. Dale. 2, T. Mcintosh.

JUDGE.—Mr. W. A. Blakston, Sunderland.

MANAGEMENT OF BIRD SHOWS.

As the time is fast drawing on when fanciers of cage birds will be busily engaged in sending their various specimens for exhibition, I should like, as one of the fraternity, to call the attention of committees and secretaries of bird shows to a few defects which may and do arise in their management. I was much amused the other day, if not a little vexed as well, on receiving my birds from a show (less than a hundred miles away) twenty-seven hours after it had closed. The birds were sent properly caged, enveloped in a wrapper, and well tied up with a strong cord. Thus packed they went as one parcel, booked through for Is. 3d. They were returned as two parcels, wretchedly packed, minus the cord, not booked through and the carriage was 2s. 10d. One of the best birds has since died from exposure. Now, if secretaries or their deputies would only take the trouble to observe how birds arrive packed, and return them in like manner, care being taken when unpacking that all cords, wrappers, &c., were systematically stowed away, I am sure we should hear fewer complaints from exhibitors. Secretaries must not imagine that because they receive no written complaints, on that account there is cause for none, and that none are made. I am well aware the duties of secretaries at such times are both "anxious and arduous," but exhibitors and their birds should receive the best of treatment from all show officials, and particularly those fanciers who do their utmost to uphold all well-regulated exhibitions by sending their specimens at no small risk, certainly at no pecuniary advantage. Few fanciers show their birds from motives of profit. There is an indescribable degree of interest and excitement in conjecturing beforehand what will be the position of such and such a bird, particularly so to the true fancier—he who breeds his own birds, and whether he will have the same rivals as last year, and what will be their relative positions. Such, I believe, are the feelings which move the majority of exhibitors.

Again, how much better it would be if secretaries would distinctly state when specimens will be returned; for fanciers residing some miles from a railway station, and beyond the limits for delivery, may have a whole day or more wasted in fruitless journeys after them. Catalogues, I think, ought to be forwarded by the first post after the awards are made, time, of course, being allowed for marking them. Fanciers like to know as soon as possible, especially when they pay for it, what their birds have done, and surely there is nothing unreasonable or impossible in expecting a catalogue twenty-four hours after the judge has made his decisions. Secretaries, too, and this is a matter of the greatest importance, should give strict injunctions to have all birds booked through if possible. This

not only reduces the charge for carriage very considerably, but, what is of far more consequence, enables birds to reach their destination much earlier than they could possibly do if they had to be dragged out at some intermediate station to be re-booked and await the arrival of the next train—frequently some hours. It is true the booking of parcels is generally done by lads who, either not knowing or not caring to ascertain to what places they can book through, despatch them to the next principal station, and leave them to reach their destination as best they may. This I have experienced over and over again, and it must stand to sense that if parcels can be booked through one way, say from Derby to Newcastle, it is only rational to expect to have them booked through from Newcastle to Derby. I am well aware that railway people are anything but obliging, but I think committees and secretaries of exhibitions of all kinds should do their utmost to enforce justice.

Another suggestion I would make is that Belgian and Lizard Canaries, usually shown in open wire cages, should be so placed in the exhibition-room as to be free from all draughts. They are naturally more delicate than the other varieties of the Canary, and, in order the better to protect them, a screen of calico or hunting, or any other material, might be advantageously erected. Belgians, generally placed first on the list, should during arbitration reverse their position, or be judged last, for this reason—they are birds which bear travelling but badly, and if judged shortly after being unpacked are frequently "rough" and unsteady. This arrangement would at any rate give them a little more time to compose themselves, and better display those peculiar characteristics which are so marked in the Belgian Canary, and on which their relative positions must depend.

A little more attention on the part of committees and secretaries generally would do much to encourage fanciers to send for exhibition specimens which they have hitherto deemed too valuable, and so tend to raise up more fanciers and exhibitors of that beautiful bird, the Canary, the keeping of which is a recreation that, if innocently pursued, is one of the most interesting and instructive.—JAMES N. HARRISON, *The Lawn, Belper, Derbyshire.*

THE NEW METHOD OF CONTROLLING THE FERTILISATION OF THE QUEEN BEE.

Some time ago there appeared in the columns of your valuable paper two or three communications, the purport of which was to give further enlightenment to the bee-master on the very important matter of queen-impregnation. This remarkable discovery hails from Yankeeland, and is quite equal to any of the big talk we are accustomed to hear almost any day from the same quarter. It has now for a long series of years been regarded as a settled fact amongst apiarists that the young queen not only leaves the hive, but that the contact is actually when she is on the wing; but according to our American cousins this may be accomplished by a different method, the *modus operandi* being to place the young princess along with a number of males in a small box or glass globe in which they are able to fly, not forgetting the necessary supplies, to shut them up, and in the course of forty-eight hours at the longest fecundation will have been secured.

At first when I read this new method I looked upon it with the gravest suspicion, and had very strong doubts regarding the practicability of a thing so far from the natural instincts of our little favourites, but which if true would be a valuable addition to apiarian science. A friend and myself, therefore, resolved to make the experiment and see if such could really be accomplished. Accordingly on a fine day about the beginning of the month (August), we opened a hive and removed from it a beautiful young Ligurian queen a number of days old, and which we were very anxious should meet with a pure mate, placed her in a box (certainly not smaller than those recommended), in company with a number of the opposite sex, shut them up, and allowed them to remain in this condition for twenty-four hours, at which time we had a survey and found her ladyship fine and lively, but the most of the drones dead, as we supposed from dashing themselves against the sides of the box, certainly not from any exhaustive cause. A fresh lot was added and allowed to remain for the same length of time with a like result. This, now, being all that was necessary and more than sufficient for us, we both pronounced it nothing short of Yankee bunkum. Chagrined, disheartened, yet not

altogether di-appointed, we returned our aspirant after regal honours to the home from which two days previously she had been rather unceremoniously removed, and on the next day to our great delight we saw her sally forth on what proved to be her wedding trip, and after a fifteen-minutes anxious watch saw her return safely, bearing unmistakable evidence that the object for which she had undertaken the journey had been accomplished. So far this is my experience, but should any other of your correspondents have tested the American statement, I shall be very glad to hear their opinion on the matter.—A STEWARTON APIARIAN.

I HAVE had my attention directed to two or three communications which appeared in the Journal regarding a "New Mode of Controlling the Fertilisation of the Queen Bee," a discovery stated to have been made by Mrs. E. S. Tapper, of Iowa, U.S., and corroborated, it appears, by others. If this were an established fact it would completely overthrow the whole views and findings of our best and most eminent bee-writers, and the discovery would be welcomed by practical apiarists as an inestimable boon, not only as respects the rearing and propagating of different varieties of the honey bee, but also in securing the fecundation of queens reared at seasons of the year when weather influences render such an event out of doors extremely hazardous and uncertain, if not impracticable.

From my own experience, however, on this subject, which extends over a considerable number of years, I never had any reason to doubt that the fecundation of the queen bee took place only in the open air. Indeed, there is no fact, I think, better attested in the natural history of the bee than this; and that although, in the language of Dr. Bevan, the queen were confined "amid a seraglio of males," yet a barren or abnormal queen she would ever remain. But we are told that by adopting either of the following methods we can control the fertilisation of the queen bee:—

1st, "Put the queen with the selected drones, and some honeycomb containing honey, in a box having a sliding cover and plenty of small gimlet holes through the top and sides for ventilation; remove the honey-board, and place the box on the frames, so that the queen and her companions may be kept warm; put on the cap, and leave them two or three days, and at the end of that time your queen will be purely fertilised."

2nd, "On the fifth day after the queen is hatched, or earlier if you choose (says Mr. Thomas in describing Mrs. Tapper's method), catch the queen and confine her with four or five select drones in a wire cage, with honey in the comb or in a sponge, and place the cage on the top of the nucleus or stock from which she has been taken, and let her remain from twenty-four to thirty-six hours, covering her up with the cap so that it will be quite dark. She will be fertilised, and commence to lay soon after being liberated."

3rd, Mr. Dux, of Güns, Hungary, confines along with the queen about one hundred bees. "The glazed box," he says, "is then darkened, and between the hours of eleven and three a drone is added, when you may watch their intercourse. If this does not occur on the first day, which, however, is generally the case, before three o'clock, it will take place the next day about the same time."

A Mr. Moore, of Ohio, however, has stated even a simpler process still. He has succeeded, he says, in getting queens fertilised "by confining them with a few drones under a wine-glass or tumbler placed in the sun; also by confining them in a lamp chimney, with the upper end stopped by a cork, and the lower end fitted into the feeding hole on the top of the hive, egress in this direction being prevented by means of wire cloth."

Mr. Woodbury, I observe, in alluding to the Hungarian method, thinks it a very feasible one, and far the most likely of any that has yet been devised to secure the end desired; but I must confess I am very sceptical as to any one of the plans succeeding. Let us consider the matter. In what respect do the circumstances in which the virgin queen is placed in the Hungarian method differ from those in which we experimental apiarists find her in our various operations a hundred times? Is it by reason of the queen being alone in company with the males that success attends the experiment? I fear not. I have more than once confined drones along with a queen under glass, and have witnessed nothing but mutual indifference and repugnance to each other; and intelligent apiarists are familiar with the case recorded by Huber, of his

having constructed a cubical glass box 8 feet high in connection with a hive containing a virgin queen. Her exit to the open air was prevented by a contracted entrance, but she had free access to the box by means of a glass tube, where she frequently betook herself every fine morning along with the drones; but though the experiment extended over fifteen days under a constant watch, yet no evidence was afforded of impregnation.

Again, is it because of the scantiness or paucity of the bees along with the queen that the desired object is attained? If so, why should not the same result follow in a hive where the bees, equally scant in numbers, have perfect freedom of exit? Such, at least, appears to me to be the logic of the case. But reasonings have no force in the face of facts. To the test, therefore, let us go.

It so happened that at the very time that Mr. Woodbury expressed his regret at being unable to experiment so late in the season, I had in my apiary two young queens in process of rearing. In one of the hives, a very large one, the bees were, from certain circumstances, reduced to two or three hundred. The queen remained, to my certain knowledge, unfecundated in this hive for several days, though of proper age, and in the society of males, the weather not permitting her to go abroad. But why was this if the fact be an accredited one, that the queen could be fecundated in the interior of the hive? The space was large, the population scanty, and no disturbing influences of any kind were present to prevent the desired object. But my experiment, perhaps, is defective. I must detach a still smaller number of bees, and confine them along with the queen, separating them by perforated zinc from the other moiety, and placing the prisoners over the hive in order to succeed. Well, I did so, and introduced, according to directions, selected drones to her majesty, and after two days' confinement allowed her and her associates to descend, but no evidence was forthcoming that she was fecundated. In the meantime the marauding bees began to pillage the hive and its scanty population offered but little resistance. I examined the interior occasionally, and now found the queen encased by the entrants and much injured. I immediately dissected her in order to set all doubts at rest, and found that a virgin queen she still remained.

Such being the result in this case, I did not submit the other queen to the like ordeal, as I might. Whether by repeated experiments a more favourable result would follow is another question; but in the case tested with every care and according to the directions prescribed, I find no evidence whatever of the truth of this new theory of queen-fecundation, and I here simply desire to record the fact.

The Köhler process I consider almost valueless and impracticable in this country.—J. LOWE.

THE HUNGARIAN METHOD OF CONTROLLING THE FERTILISATION OF THE QUEEN BEE—Mr. J. H. Thomas, the apianian editor of the *Toronto Globe*, after describing Mr. Dax's method of controlling the fertilisation of queens, says—"The above process, it will be seen, is very similar to the method already described in this Journal. We have experimented with one queen, and succeeded in getting her artificially impregnated."

OUR LETTER BOX.

WAKEFIELD SHOW.—We are informed that the Cochia chickens that won the cup are the property of Lady Burrell, and not of Mr. George Fletcher.

PROFIT FROM POULTRY-KEEPING (R. R.)—It is almost impossible to answer your question. To keep twenty-five fowls profitably you should have at least three-quarters of an acre, and part of it should be submitted to the landscape process we described some weeks since—that is, if chickens are to be reared. We cannot understand profit without breeding, except in some localities where new-laid eggs sell well. In such places fowls properly managed are very profitable, the eggs selling at 3d. or 4d. each, and often more. If you do not intend to breed you may keep twenty-five fowls well on a quarter of an acre. If you have not so much you may keep them on less, but when space diminishes profit-making must increase.

ROVEN DUCKS (J. Dove)—You are overfeeding your Ducks, and they are consequently most likely unwell from fat. Such a dietary as you name would only be excusable if you were feeding for exhibition where weight was the only merit. Give barley meal and a little Indian corn, but discontinue the sheep's entrails. Compel them to take a little exercise, and allow them a swim if possible. They will then most probably regain the use of all their members.

GUINEA PIGS.—Constant Reader wishes to know if any colour or kind is to be preferred of these unprofitable little animals.

DRIVING BEES (H. Marshall)—Bees will not quit their own well-furnished domicile for an empty or even a partially furnished hive merely because the former is capized and the latter placed over it. They require to be expelled by "driving," in the manner described in page 60, of the last edition of "Bee-keeping for the Many," which is now being reprinted.

ANTS IN DWELLING-HOUSE (I. L. T.)—Try sprinkling Scotch snuff in and around their haunts, and in the places which you especially desire them not to invade.

FLIES (B. C.)—We know of no mode of relieving a sitting-room from flies except opening the windows, driving them out by buffets with a handkerchief, and then closing the windows.

DRESSING RABBIT SKINS.—"W." will be glad to be informed the best way to preserve the skins of White Rabbits to be used for fur trimming.

METEOROLOGICAL OBSERVATIONS

In the Suburbs of London for the week ending September 13th.

COVENT GARDEN MARKET.—SEPTEMBER 14.

CONTINUOUS heavy supplies of goods prevent any better prices from being obtained, and we find large consignments of French fruit coming to hand that, but for the war, would have found their way to Paris, all tending to glut the market. Peas now comprise Marie Louise, Louise Bonne, Bon Chrétien, and Beurre d'Annonis. The best varieties of Apples are Ribston Pippin, Downton Pippin, Ingestrie, and Kerry Pippin. Regents Potatoes, 9s. to 110s. per ton; Kidneys, 110s. to 120s. per ton.

From observations taken near London during the last forty-three years, the average day temperature of the week is 65° 8', and its night temperature 44.2°. The greatest heat was 82°, on the 25th, 1832; and the lowest cold 23°, on the 25th, 1856. The greatest fall of rain was 1.68 inch.

THE GREENHOUSE OF ONE HAVING A SMALL INCOME.—No. 1.

HOUGH my income is rather limited (not over £100 per annum), it was my good fortune about four years ago to become the possessor of a small span-roofed greenhouse, and I wish to tell the readers of this Journal how I stocked it with plants, and how I grew them. At that time I was not a reader of this nor of any other horticultural paper, and hence did not know of the existence of Editors who would answer any question you

proposed to them in regard to stocking a greenhouse. But supposing I had known of their existence, and supposing they had given me such a list of greenhouse plants as they have given to other inquirers, I would have had to say, after consulting the priced catalogue of greenhouse plants which I kept constantly near me, "I cannot afford to purchase them, and hence must content myself with an empty greenhouse." But I quite meant to stock it, and hence resolved on availing myself of the resources I had at command.

Well, I had a few Heliotropes, Verbenas, Fuchsias, and Pelargoniums growing in a frame, and these I transferred to my greenhouse, intending some day to supersede them with plants which rejoiced in much longer names; but I have never done so, and never mean to do so. I admit that I have added a few plants whose names were as long as their price, but with one exception, to be afterwards noted, they have never come to occupy such a prominent place in my collection as their old-fashioned brethren.

In enumerating my original collection of plants I made mention first of all of Heliotropes. If I recollect rightly, the first plant to grace the stage of my greenhouse was a Heliotrope, and while I have a greenhouse I shall always give a prominent place to this, my favourite flower. Since I have had a greenhouse it has been to me a source of considerable pleasure to visit other greenhouses and compare notes, and I have often been surprised to find how very few people grow the Heliotrope. Indeed, with the exception of my own and a few other greenhouses in the neighbourhood, I have never seen Heliotropes grown to such a state of perfection as they are capable of. The plants which I grew and flowered in my greenhouse this year were three years of age. They were 5 feet in height, were grown in the form of a pyramid, and were clothed from top to bottom with handsome dark green foliage and fine trusses of lilac flowers, contrasting beautifully with their gayer neighbours the Fuchsias and Pelargoniums. The only difficulty which I have experienced in growing old plants of the Heliotrope was to get them to break freely in the spring, but I have no longer any difficulty in this direction.

The manner in which I grow them is as follows:—In the spring I select several of the strongest autumn-struck cuttings, and pot them off in rich soil, giving them the benefit of the bottom heat of any frame which I may have in operation. In a few days they commence to grow vigorously,

after which I carefully stake up the main stem, and pinch in the lateral branches. In a month they are ready to be repotted. I then give them a 6 or a 7-inch pot, and soil consisting of three parts rich turfy loam and one part good rotten manure, with the addition of a little silver sand, and replunge them. When they have again begun to grow I take them to the greenhouse, and give them the place which they are to occupy during the summer, taking care never to let them suffer from want of water, for I know no plants which suffer more owing to neglect in this direction. If they are carefully attended to and nourished with frequent applications of weak liquid manure, they will grow and bloom abundantly during the summer and up to the end of August. At that time I take them out of the greenhouse, and lay the pots on their broadside, withholding water from them. A week or ten days will suffice to ripen the wood and strip the leaves off them, after which I replace them in the greenhouse, taking out the old stake and replacing it with a longer and stronger one, to which I tie the main stem as well as the lateral branches. And herein lies the secret of successful growth—I used to cut off the laterals, and treat the plants as Fuchsias, but they would not break so freely as I could wish, and hence in several places the bare brown stem was conspicuous, detracting from the beauty of the plant; but since I began to tie up the laterals close to the main stem all difficulty has vanished, for the laterals break quite freely.

By the end of September the plants begin to throw out side shoots, which will increase to an inch in length before the growth is suspended. All that they require during the winter is a little water occasionally, and to be kept free from frost. In March give them quite a liberal shift. Let the pots be at least 10 inches in diameter, and the soil as formerly recommended, with the addition of half a handful of dissolved bones above the drainage of the pot. It is not easy to reproduce the fine dark shade of green in the foliage of plants grown in-doors which you will find in plants grown out of doors in rich soil. But the bones, with the rich soil, abundance of pot-room, and liberal supplies of liquid manure will work wonders.

Another point to be attended to is the regular pinching-in of the side shoots until you have succeeded in making compact bushy plants, after which they may be allowed to flower.

I hardly know anything finer than a well-grown Heliotrope. What a delicious odour the flower emits, and how finely it contrasts with other plants! In my greenhouse this year I had four plants of the dimensions formerly described, two of these being Reine d'Hiver, and the other two Miss Nightingale. Reine d'Hiver is a very fine Heliotrope either for greenhouse culture or for outside decoration. In colour its flower is of a rich violet with a yellow centre, and the plant is a most abundant flowerer. It is far superior to the old peruvianum and Voltaireanum. There may be finer varieties in cultivation now. Indeed, in your answers to correspondents, you speak of a Beauty of the Boudoir as being the best in cultivation; and really, if it is much finer than my favourite, I should like to make its acquaintance. However, no one need be in difficulties in

regard to acquiring a stock of *Heliotropes*. I see from some of the catalogues that half a dozen cuttings of the best varieties will be sent for a dozen stamps, and half a dozen is a large enough stock for any greenhouse. I am satisfied that to inexperienced amateurs, such as I am, a shilling's worth of *Heliotropes* will afford as much pleasure as a pound's worth of plants of a rarer kind; not that I mean to disparage the latter, but when cuttings of *Heliotropes* and other plants are to be obtained at such a cheap rate, no one need be at a loss in regard to stocking a greenhouse.

It will be at once apparent that I am writing for the encouragement of amateurs as poor as myself, but who do not happen to have as much experience—not that I have much. Indeed, I am not without my fears that your learned readers may be shocked by some things which appear in my paper. I can only say, I am not learned, but am learning, and hope some day to be able to entertain a more highly educated class of your readers than I am addressing at present.—H. S.

PLANTS FOR BASKETS AND VASES.

(Concluded from page 198.)

TROPÆOLUMS.—After trying a great number of varieties, including a fair proportion of seedlings, I am sorry I cannot give them such a good character as I should like. That they flower abundantly cannot be denied, and even the varieties whose principal fault when grown in the open ground is the great length of their leafstalks hiding or concealing so much of the flower, are not objectionable in the vase; but the trailing *Tropæolums* never seem to me to be at home in such a place; the long dangling shoots are few in number, and hang in anything but a graceful manner, struggling to move up and catch hold of something for support, and every wind tosses them about in a manner that soon renders them the reverse of beautiful. The place for a trailing *Tropæolum* is where it can cling to something for support, and ramble over roots or amongst branches, instead of hanging in mid air. The dwarfier varieties, however, are more at home in vases; they flower, perhaps, more abundantly than when in the open ground, and the habit is all that can be desired. Perhaps a few short branching sticks put in amongst them may help to secure them against high winds where much exposed, for they are not very strong at the neck, but in general their compact growth renders them easily managed, and nothing can exceed their abundant blooming. The yellow varieties, perhaps, exceed the scarlet in this respect, and certainly they are more useful, as yellow-flowered vase plants are the less plentiful; but there are some dark-coloured varieties as well, and many intermediate shades. A good white *Tropæolum* would be valuable; perhaps there may be one, but I have not seen it.

CUPREA PLATYCENTRA.—Differing widely from the above is this plant, which I would not recommend as a competitor to the *Geranium* in every place, but where there is a vase in a shady situation it comes in very well; it is also good late in the season, flowering during the autumn until a nipping frost cuts it off, but rain does not seem to injure it. Its spreading habit renders it suitable for occupying a vase by itself without the accompaniment of other plants, but I have known a white-flowered Ivy-leaved *Geranium* look well when employed as an edging to it, and the plant next mentioned is also well suited for the same purpose.

ARCTOTIS REPENS.—This has never become so popular for bedding as it deserves to be, but as an edging to other plants in a vase or basket it is valuable. Its beautifully frosted stems and foliage differ widely from those of ordinary pendent plants; indeed, its growth shows but little indication of hanging, as it extends horizontally from the edge of the vase, forming a sort of frame or guard to the centre, in the same manner as the guard petals of the *Anemone* or *Hollyhock*. Without pruning or training it gives a star-like outline to the vase, setting off to advantage a cluster of scarlet or other dark-flowered *Geraniums*. It may be used with advantage as an edging to most plants having green or dark-coloured foliage. It is not hardy, although it will bear a considerable amount of cold. This *Arctotis* is easily propagated, for when lying on the ground every joint strikes root. As an edging, it requires but little trimming, excepting, perhaps, directing some of the wayward shoots, and picking off a few of the old leaves in the centre of the plant, which have a tendency to become brown during the summer months. This, however, is not always the case, and in the present season there seems to be less browning than

usual; indeed, I have never seen anything to complain of it as a vase plant on that account.

SEDUM FABARIA.—The sturdy habit of this plant, its glaucous foliage, and its free-flowering character, entitle it to mention as a vase plant, and its value is further enhanced by its being perfectly hardy, plants in vases having survived the winter and grown well. For very small vases, where only one plant can be employed, I do not know anything better than this; and in a larger vase, if edged with some other plant, it is also of great service, as it never has an untidy appearance. It is astonishing how large a plant of this will grow and flower in a small vase, requiring no support nor attention of any kind save watering; but even if this be neglected, the plant seems to bear neglect better than many of its class. The flowers are also numerous, and, though not bright, are elegant. There are some other species of *Sedum* resembling this in outward form, but not so well adapted for the purpose, but I have never been able to make much of the dwarfier or horizontal-growing kinds. *S. azoricum variegatum* is not so satisfactory, neither is *S. Sieboldi variegatum*, there not being sufficient clearness in the white colour of either; and *S. Kämpferi* is likewise only an inferior kind, while *S. glaucum* is more ornamental in winter, its extreme dwarfiness rendering it only useful for covering the ground. Other species are only suited for the same purpose.

PORTULACAS.—Bright, gay, and varied to a degree not equalled by any other plant, these highly-ornamental annuals are, nevertheless, somewhat capricious. In 1868 I had some very good examples in vases of very limited size, but they were very small both last year and in some previous seasons, and I can therefore only give them a qualified recommendation. For very small vases, however, they may be tried, and may do well, requiring no attention after planting beyond watering at times, and picking the dead flowers off to prevent the plant exhausting itself with seeding. The extreme brightness of the colours of the flowers cannot well be matched in anything else, and when at their best the *Portulacæ* are everyone's favourites.

MESEMBRYANTHEMUMS.—A small-leaved species named, I believe, *insigne*, has often been used here as an edging to plants of more robust growth. It is a compact-growing and elegant plant, with abundance of starry flowers of the richest magenta colour. It is nearly hardy, not unfrequently withstanding the winter even in an exposed vase. Other *Mesembryanthemums* of more robust growth may be tried, but I have not found any equal to *insigne* for general usefulness.

CENTAUREA GYMNOCARPA.—The fine habit and form of this render it suitable for planting as a centre, to be surrounded by some other plant of a darker colour; but it requires somewhat more nourishment than the majority of vase plants. It is superior to *C. candidissima* for general effect, nevertheless I would not recommend it excepting where variety is wanted.

IRESENE HERBSTII is late in coming into fine condition, unless good plants are put in at first, but with liberal treatment and a favourable autumn it is often very effective. It stands the wind better than the *Coleus*, and is a good autumn plant, perhaps the best in its way.

ECHVERIA METALLICA and other species are better fitted for a sheltered corner or small formal bed than for vases, where *E. secunda* is held in great esteem. I have seen a rather good effect produced by planting a number of small or middle-sized plants of *E. metallica* around the edge of a vase, with a large centre plant of another species, I believe an *Aloe*; but I am not an admirer of such plants in general, and hardly think the vase a suitable place for them.

Having now run through most of the subjects usually planted out for summer effect, I come now to hardy plants, which may be used either for winter display, or to occupy a permanent position. For the latter purpose some variegated *Ivies* are useful, and a good-sized vase with a *Fuchsia* in the centre and *Ivies* hanging round the outside is by no means a bad arrangement, for though the *Fuchsia* may die down in winter, the vase will still be furnished, and the *Fuchsia* spring up again in summer. The Japanese *Euonymuses* may also be employed in the same way, and there is certainly less likelihood of their running into the green state when they are so treated. Much has been said of the value of *Vinca elegantissima* for this purpose, but it is not without its drawback, as the shoots, by dying off in winter, necessitate a new growth, which, by first rising upwards, does not acquire a pendent character until the summer is far advanced, especially if the plants are cramped for room, and, perhaps, imperfectly supplied with water; nevertheless, I think the variegated *Vinca* will have to rank high as a winter

or continuous vase plant, as its graceful habit, when the plant is really good, cannot well be improved upon.

Of plants which may be temporarily placed in such a position for the winter, the most effective we have is *Helleborus foetidus*, a Palm-like plant with dark green foliage. It flowers in midwinter or very early in spring, and has well-shaped pale green blooms, the contrast of the two hues being very effective. The plant is easy of transplantation, its numerous fibrous roots allowing of its removal almost without injury, and it is amongst the hardiest of the hardy. Some of the *Sempervivums* are also suitable for outer edgings, but I have only used *S. californicum* and *S. globiferum*, these and *Sedum glaucum* being sufficient, in general, as dwarf plants, for it is not unusual to plant bulbs and early spring-flowering plants in such places. Among the latter the whole family of *Primula* affords great diversity, as well as the variegated and plain-leaved *Arabis alba*; in fact, this class of plants may be extended to any length, for in a large vase or basket evergreen shrubs of more kinds than one may be so employed, as well as the hardy early-flowering plants.

I now come to plants not fitted for vase work in summer, and as the negative here is as important as the affirmative, I believe the following may be considered as unobtainable, although they rank amongst the greatest ornaments of the garden at the time they are in bloom. *Calceolarias*, *Verbenas*, and *Ageratums* all require more support than they can obtain in a vase, and the same may be said of *Lobelias*, *Salvias*, *Nierembergias*, and some other plants of strong growth, as *Pentstemon*, most of the *Fuchsias*, and *Petunias*, excepting where they have plenty of room. Few annuals do well, excepting dwarf French *Marigolds*, but I have sometimes been successful with several of the summer annual creepers, as *Lophospermum*, *Manrandya*, and the *Canary plant*; but generally they present an immense hump just over the collar of the plant, and the shoots seem rather inclined to plait themselves into a sort of thong rather than to spread out in a graceful manner, like the Ivy-leaved *Geranium*; consequently I now rarely use them, but it is possible some of the newer annuals may be better adapted for the purpose. Only such, however, as are capable of thriving on a limited supply of food are admissible.

The list of vase and basket plants which I have given is far from complete, and I shall be glad if others will supplement it with the names of plants which they have found suitable.—*J. ROBSON.*

P.S.—In page 197, second column, ninth line, for "lawn drain" read "sewer drain."—*J. R.*

THE NEW GRAPES.

SOME time ago a correspondent of "our Journal" complained of his being unsuccessful in making plants from eyes of the *White Lady Down's Grape*. I wrote to Mr. Methven, who kindly supplied me with some eyes, and every eye became a plant. This variety is late in starting, as stated by Mr. Thomson and Mr. Methven, but good in constitution, and in all respects equal to that good Vine, the *Black Lady Down's*. I recommend all to try it. No bottom heat was used, I never do employ it, as more fruitful hardy plants are obtained without it.

Madresfield Court is excellent in constitution, as free as *Frankenthal*—in my estimation the best of all the *Hamburgs*. This is growing strongly and well out of doors against a wooden fence with a south aspect, and on this stock I graft my *Vinea* grown under glass. I offer Mr. Cox, the raiser, my thanks. I think very highly of this *Grape*.

Golden Champion is equally satisfactory, and succeeds perfectly in a house without fire heat. Of my grafted *Vinea* fruiting I cannot yet speak. This has been stated to be the largest *White Grape*; it is a noble fruit, but not so large as *Canon Hall Muscat*.

Of Mrs. Pince, the grafted plants still maintain the first place; this I recommend.

Royal Black, Perpetual Grape, or *Royal Ascot* is very free; the smallest eyes soon make good plants suitable for pot *Vinea*. I have large plants variously grafted; of them anon. In January last a brother amateur sent me some good eyes. I was very successful in rooting them, growing them on in the same way as softwooded plants for flowering, and stopping them. Although this seemed a "very fast" proceeding, I also read in a catalogue now before me that "on the 28th of May, 1868, a house was planted with small canes raised from eyes since the February of the same year (*i.e.*, 1868), which in the October

following had an abundant crop about the size of marbles to ripen during the winter months." I have many plants of this *Vine*, and if it be possible for it to perform in such a manner, it will be the best of all *Vinea* for thousands of small *Grape-growers*, and the raiser deserves public thanks. With me the laterals have not given any fruit, and the plants seem likely only to break at the upper three or four buds of the rods. I send some leaves and three of the laterals for the inspection of the Editors, to show the health and vigour of the *Vinea*, and I shall be glad of information as to growing the *Royal Ascot* in this manner, as so far, with me at least, it is a failure. I shall, however, try again and again if any hopes of success appear, and report progress.—*R. M. W., Fir View, near Sheffield.*

BEDDING GERANIUMS.

As mentioned recently in your columns, this has been an exceptional season for bedding plants, but I send a few notes which may be of interest to some of your readers, having seen all the best new and old varieties of *Geraniums* bedded out and grown as pot plants. I would certainly advise your correspondent Mr. Peach to give them a trial.

First I will notice the scarlet zonal *Jean Sisley*, which will surely become the favourite. It stands the weather better than *Vesuvius*, has a finer-shaped flower with a large, conspicuous white eye, and in brilliancy of colour excels all other *Geraniums* that I have seen either as a bedding or a pot plant.

Next I will speak of the *Stella* class. *Giant des Batailles* is the most abundant bloomer I ever saw, being a great improvement on *Vesta*, *Bayard*, *Waltham Seedling*, and many others of this class. The colour is more intense, and the plant never exceeds about 8 inches in height. *Charlie Casbon* is an improvement on *Lady Constance Grosvenor*, *Cytister*, and many others; it is a most profuse bloomer, produces fine trusses, is very dwarf, and must take the place of the above.

Of semi or Hybrid *Nosegays* *Claude Lorraine* is an improvement on *Dr. Hogg*, for its colour is splendid; the plant is of a fine habit of growth, and the flower of a nice shape; it is the first nearly purple *Geranium* sent out. *Docteur Muret* has orange-scarlet blooms of immense size, and is a very fine grower. Everyone ought to grow it as a bedding or a pot plant on account of the large size of its blooms.

There has been of late a great stride in the *Christine* class, *Beauty of Lee* being a first-rate badder, also a good pot plant; it is of the most intense bright scarlet pink, a good grower, and the best for large beds. Having seen *Magenta Christine*, *Advancer*, *Mrs. C. Cletons*, and *Beauté de Suresnes* growing side by side, I find *Magenta Christine* is the best bloomer; the trusses are smaller, but very abundantly produced. For small beds this is a gem. *Advancer* stands next; it is a self-coloured flower, and good for general bedding purposes. There is a variety not yet sent out called *Master Christine*, which will no doubt eclipse all in this section, and will therefore take their place, being the most abundant bloomer and the richest in colour of any. I have seen this in all stages of growth, likewise at the *South Kensington Exhibition*, where it was awarded a first-class certificate, and was admired by everyone who saw it.

I will now notice the white section. Having seen *Purity*, *White Perfection*, *Madame Martha Vincent*, *White Wonder*, and *Turner's Bride*, I find the last the best, it being a fair bedder and a good pot plant. The flowers are large and circular, with broad overlapping petals, and far superior to any of the *Madame Vaucher* class.

Before closing these few notes I will refer to bedding *Tricolors*. It has been a most trying season for this class, a great many losing their colour and foliage. *Lady Cullum* and *Florence* certainly retain their colour the best; the latter is the better of the two.

Of the *Golden Bronze* bedding varieties which are now acquiring a fine colour I may mention *Plutus*, *Sybil*, *Rev. Mr. Radcliffe*, *Kentish Hero*, and *Crown Prince*. The last-named takes the lead for every purpose, its colour being amongst the most intense; yet it stands the sun admirably, always retaining its splendid zone, and is in every way distinct from the older varieties.

Of the plain yellow-leaved section I have taken much notice of *Creed's Seedling*, which is a most profuse bloomer, producing a number of scarlet blooms long and continuously, and the plant rarely exceeds about 8 inches in height. It makes a splendid bed. Of *Yellow Boy*, *Golden Beauty*, *Star of Gold*, *Golden Emperor*, *Golden Queen*, *Yellow Sovereign*, *Little Golden*

Christine, and Yellow Christine, the first three are decidedly the best, retaining their colour better than any of the others this hot season. I feel fully convinced, had all your Geranium correspondents had the opportunity of seeing the best varieties side by side, that they would have endorsed my opinion.—J. F.

POTATO CULTURE—ALPINE STRAWBERRIES.

I HAVE this season tried allowing only one shoot on each seed Potato to grow, and as you solicit your readers to give the results of their experiments the following is at your service.

I planted a small piece of ground with Rivers's Ash-leaved Kidney. Each row consisted of an equal number of sets 9 inches apart. One row I took under my own especial care, the remainder were planted by my gardener. My sets were planted in a box of pure leaf mould and placed in the greenhouse; as soon as they broke through the surface they were planted carefully in the ridge allotted to them.

The whole were planted in ridges, and each set was put in 9 inches deep; in the hollows were subsequently planted rows of Brussels Sprouts.

The haulm of the general crop died down a full fortnight before my single row showed any symptom of decay, so that the latter commenced growth earlier and continued it longer than those treated in the ordinary way. The result was that a selected row of the latter yielded 7½ lbs. of Potatoes, whereas my row, taken up three weeks afterwards, produced 12 lbs. of very much finer tubers. It was a fair trial in every respect.

Many of your correspondents have been lately writing upon Strawberries, and at page 180 Mr. W. Hindson, of Chase Cliffe, gave his useful experiences on the best sorts to grow on light soils, but neither he nor any of your correspondents ever mention the Alpine Strawberry. What can be the reason of this? It appears to me that it ought to be in every garden. Two years ago I had a packet of seed in one of the collections sent out by the Royal Horticultural Society. Plants came up by hundreds, and were planted out 6 inches apart. They yielded fruit in six months—say seven, I forget to a day. I had some very good dishes in the spring, two months before the general fruit came in. During the heat of summer the yield was scarcely worth collecting, but on the 10th of this month a large dish was picked, and they will go on until the end of October. They are a small fruit, it is true, and they have not the flavour of a British Queen, but broken up with sugar and a dash of claret they are delicious, and then Strawberries in September and October are not to be sneezed at. Again I ask why they are not more cultivated. They will grow almost anywhere—under hedges, under Gooseberry bushes, and our neighbours the French scarcely have anything else—in fact, until the last few weeks positively nothing else; at least, if I am right in believing them to be the same as they call "Tous les Mois." I can detect no difference. They have a drawback—everything has—they throw out an infinity of runners, which take root easily, and without attention become matted together. Will any of your clever and able growers explain why this class of Strawberry is never spoken of or recommended?—H. WATSON, *Old Charlton, Kent.*

DYMOND PEACH.

THE history of this Peach is soon told. The late Mr. Veitch, of the Mount Radford Nurseries, Exeter (grandfather to the present Messrs. Veitch, of the Royal Exotic Nursery, Chelsea), met with it in the garden of a gentleman named Dymond. Mr. Veitch saw the good qualities which it possessed, propagated it extensively, and called it the Dymond, and it is now widely distributed over the western counties under that name. I never heard Mr. Veitch mention it as a new variety; but if it was not new it was a sort he did not know, and from the many good qualities it possessed he strongly recommended it to all fruit-growers. It is very hardy, a great bearer, later than the Royal George, and differs from all that section in having large flowers. It resembles the Hemskerk by the very small, round, and smooth stone. It usually ripens in Devon from the middle to the end of September, but in late seasons will last into October. The leaves are deeply and doubly serrated.—A. McKELVIE, *Torrington.*

[Thanks for the buds.—Eds.]

DAMSONS.—When Mr. Crittenden's crop of the present season is all gathered I shall have something further to say on

this fruit, and especially on the variety that bears his name.—J. ROBSON.

NOTES ON ROSES AND ROSE STOCKS.

THE Rose is my favourite, and I love her "oh, how well!" I have now exactly four hundred plants, of which three hundred are Perpetuals, and I have had the greatest of pleasure from them this year. My soil is perfection for Roses—a good rich stiff loam. The hedges bristle with the Dog Rose, but yet, in spite of the Rev. S. Keynolds Hole, give me the Manetti. I have many plants of the same varieties on both stocks; during the last two summers the result has been a long way in favour of the Manetti. Both for size, colour, and health there has been no comparison; even Manettis planted last autumn have beaten long-established Briars, especially Alfred Colomb, Charles Lefebvre, Fisher Holmes, Victor Verdier, and Dr. Jamin. They were failures on the Briars. Mildew set in very early, but I soon subdued it on the Manetti; I was powerless on the Briar. May this not be one great cause—the long stem of the Briar is so acted upon by the sun that the nourishment cannot make its way to the head before it is dried up by the sun? In future I shall have nothing on the Briar but strong-growing Tea Roses.

I have a plant of Unique planted out last May; it has now made a grand plant, and is flowering most abundantly. Marie Sisley refuses to open out of doors, but has done well in a pot in the conservatory. I let me recommend my brother amateurs if they want always to have a Rose in their garden from which to cut a lovely bloom, to invest in two or three plants of Archimède; with me it is beautiful. I see but little mention of Charles Margottin in the various letters on Roses; with me (in Somerset) it is grand.—STIFF SOIL.

NOTES FROM BELFAST.

IN the well-known and excellent Botanic Gardens at Belfast on the 8th and 9th inst., was held the first, we believe, of a series of great horticultural exhibitions after the style of the Regent's Park and Manchester Shows, which have never failed to please. Horticultural exhibitions in Belfast are not new things; they have, however, never been particularly successful; the late Show was, therefore, a bold attempt on the part of the Directors of the Botanic Gardens to resuscitate them, and to introduce the Belfast people to new pleasures by adopting a new style of arrangement in their exhibitions. The attempt, we are happy to state, was so far successful, reflecting considerable credit on the very energetic Curator, Mr. J. F. Johnston, under whose management the whole was carried out.

The grounds where the Show was held were exceedingly well laid out for the purpose, about 80 yards in length and 30 yards in breadth, the centre being somewhat hollowed and cut up into irregularly-shaped beds and mounds of grass, on which the plants were placed. This piece of ground had been previously prepared, and was in good condition, greatly marred, however, by the use for the walks of ugly coal ashes, which contrasted badly with beautiful flowers. A huge canvas tent was erected, supported by a great wooden framework and four lines of exceedingly ugly rough Larch trees, which proved a great eyesore. The arrangement of the Show itself was in some respects faulty; the centre, which ought to have been the chief point, being particularly bare and destitute.

Prizes to the amount of £200 were offered for competition, and very spirited in some cases was the contest. The display of Fuchsias was remarkably fine, far surpassing anything of the kind seen about London for years, those from Professor Yonghe and Mr. Hawkins being particularly fine. Zonal Pelargoniums were likewise well displayed, also exotic Ferns, for which the Belfast people seem to have a particular regard. Hardy Ferns were likewise shown in great numbers, and among them were many remarkably fine varieties. The Dahlias from Messrs. Dickson, of Newtownards, were about the largest and best finished flowers we have ever seen. Roses, for the season, were also well shown. There were, besides, some very good examples of stove plants, *Ixoras*, *Bambusa Fortunei*, *Yucca variegata*, *Sanchezia nobilis variegata*, *Cyanophyllum magnificum* and *Bowmanii*, a very fine *Croton variegatum*, and *Anthurium magnificum*. *Vallota purpurea* was particularly well shown. We only observed one "wee" solitary Orchid, which even Mr. Anderson almost overlooked. Bouquets were well represented, showing better taste than is to be found in many places.

Fruit was pretty well shown, the competition for the collection between Mr. McLacklan and Mr. Mason being very close. Black Grapes were in pretty good order, and there were some good Muscats. There appeared here with the exhibitors a slight inclination to prefer the big coarse Trebbiano to the smaller sorts. Peaches and Nectarines were wonderfully good. There were also some good Figs and Plums—Jefferson, Reine Claude de Navay, Victoria, &c., being the principal sorts of the latter. Pine Apples were at a minimum, there being only one "one-pounder." Several good dishes of Pears were shown, including fine examples of Jargonelle, the best of all summer Pears for the north. Apples were also well shown, a collection of about forty sorts coming from the gardens of Colonel Leslie, Glasslough. The Kerry Pippins in several instances were particularly fine, and this is a truly Irish Apple.

Vegetables were also well displayed. Parsnips were particularly fine, yellow Turnips and Celery very excellent, and there was a fine lot of Potatoes, consisting of Berkshire Kidney, Paterson's Victoria, Paterson's Blue, Fortyfold, and a good-looking sort called Crofill's. Mr. Meredith, of Garston, exhibited a small box of very fine black Grapes. These were exceedingly meritorious, but very badly shown. Mr. Fowler, of Castle Kennedy, had a very large bunch of Syrian Grapes, weighing over 15 lbs. This, although large, was in no respect captivating.

The Judges on this occasion were all men of sterling ability—for the plants, Dr. Moore, Glasnevin; Mr. P. Robertson, Edinburgh; and Mr. Anderson, Meadow Bank; for fruit, &c., Mr. Stevens, Trentham; Mr. Meredith, Garston; and Mr. Fowler, Castle Kennedy. It showed a praiseworthy desire on the part of the Directors to secure such high talent, and so far so good; but why should they have exerted themselves so little afterwards, the whole burden of the duties appearing to be shelved on the Curator, Mr. Johnston, who acted as Assistant Secretary?

We are pleased to state that financially the Exhibition has proved successful, being visited on the first day by all the *élite* of the wealthy and thriving city of Belfast.

THE CHILWELL NURSERIES.

THE extensive nurseries of Mr. J. R. Pearson, of Chilwell, near Nottingham, from the variety of interesting objects which they contain, possess many attractions both for the florist and pomologist; for there the culture and preparation for sale of the most useful varieties of fruits and flowers, as well as a host of other things, are carried on with such energy and skill, and such painstaking attention to minor details, as are not only most praiseworthy of themselves but highly advantageous to the purchaser.

One of the most attractive features of Chilwell this autumn is the bedding Pelargoniums, or Geraniums as they are commonly called, and to these, therefore, I purpose first of all to draw the attention of your readers. For some years past Mr. Pearson has devoted much time and money on the work of raising seedling Pelargoniums, impregnating most of the flowers with his own hands, and flowering about five thousand seedlings every year in his trial grounds. From this large number he has selected those which have appeared sufficiently meritorious to be subjected in following seasons to the severe test of a comparison with the best varieties in cultivation, with which they are planted side by side: and so he has gone on selecting and discarding with a keen eye to the development of all the most important points of excellence in this class of plants, till at length a collection has been formed of proved kinds of such sterling merit, and which are so decidedly superior to almost all the best established sorts, that I am confident they must command universal acceptance at the hands of true lovers of the flower garden. Nor does it appear that Mr. Pearson intends to rest content even with his present splendid success, for a view of his trial garden this autumn fairly bewilders one, and it was not till I saw in full bloom the thousands of magnificent seedlings which are there that I could realise the immense amount of labour which selection implies.

That Mr. Pearson sets his standard of excellence very high may be easily inferred from the fact that out of all the hosts of seedlings which have passed under his critical eye the collection of named varieties offered to the public does not much exceed two dozen in all. Of these I may select Bayard as one of which something is already known; this is a sterling variety in every respect, with an abundance of large trusses of rich crimson

flowers, and with a free yet compact habit of growth. Brighter in colour than Bayard, and with a profusion of magnificent flower trusses, is Douglas Pearson; in its habit of growth it is everything that one could wish, and I have no hesitation in naming it as the most magnificent bedding Pelargonium I have ever seen. Arthur Pearson is another useful introduction in the way of Amy Hogg, but surpassing it in every respect, especially in its brighter colour and larger petals. Then comes Othello, of a deep rich crimson, equally fine in growth and flower; this will, I think, prove a splendid variety for massing, its dark complexion being far more likely to be admired by the ladies than was that of Shakspeare's hero. William Thomson, of a deep shade of scarlet, is also a kind that will be highly valued; it forms a close compact mass, and is peculiar from its very neat and erect habit of growth. Milton, too, is another fine variety, excellent in every respect, and of a peculiar and distinct shade of colour, which may be described as a cherry red. Another, named Duke of Devonshire, with rosy red flowers, is a splendid variety, with a profusion of such huge trusses that I was tempted to measure one, which proved to be fully 5 inches in diameter; it has a compact and erect habit of growth. Mrs. Mellows has very dark rich crimson flowers, and the trusses are very large and well-shaped. An important peculiarity of the Chilwell seedlings is the duration of the flowers, for I noticed that in almost all the fully expanded trusses the flowers which opened first still remained intact.

Of other varieties of the No-egy tribe Alfred Pearson deserves mention, its stout-petaled flowers of fine form and of an attractive shade of rose are freely produced in fine compact trusses. Lawrence Heywood is also a promising kind, having a fine spreading habit, with its flowers of a deep shade of cherry with a dash of magenta. Thomas Speed another of this shade of colour, but quite distinct, has very large flowers, but it appeared to be hardly compact enough in the truss; yet its free growth, and the bold and striking appearance which a mass of it produces, are qualities very much in its favour. Nor must I omit to mention another, named Mrs. Henderson, of a peculiar shade of colour, which may be called violet crimson; it has flowers of fine form, and is a promising variety. All the foregoing kinds belong to the Nosegay section. Three other varieties of broad-petaled scarlets were very fine; these were E. J. Lowe, a splendid sort, having very large flowers of fine form, William Hill, and Rev. John Woolley.

Among the Golden Tricolors Edith Pearson, from its dense, compact habit of growth, and the brilliant markings of its very flat circular foliage, will prove a useful introduction both for pot culture and beds. Another of this section, named William Sandys, is the most vigorous Golden Tricolor I have met with; many of its young shoots were 9 inches long. It is also peculiar from the very deep green centre of its foliage, in which the yellow and crimson colours are well developed. So striking was its effect, that a mass of Sophia Damaresque growing near it made a very poor display. Mrs. Edge is also a pleasing variety, from its pretty compact growth and well-formed foliage. My last selection from this group is Monsieur Durand, and a very handsome dashing fellow he is too, decked out after the latest fashion in the brightest possible crimson, yellow, and green, and with a freshness of appearance that at once attracts one.

I come now to another distinct variety, named Pearl, a white variegated sort, having a dark zone on its foliage, but with a very broad pure white leaf-margin, having flowers of a pleasing shade of pink; it is just one of those rare gems among variegated plants in which the colours of foliage and blossom contribute to each other's beauty, in this instance producing such a chaste effect that it must become a general favourite; and I was not surprised to hear Mr. Pearson say that he was afraid he should be unable to propagate a sufficient stock of it to supply the requirements of his customers. Another silver-variegated kind with which I was much pleased, but which was not raised by Mr. Pearson, was Miss Kingsbury. Its flowers are of such a soft shade of rosy scarlet, that in certain positions they might be retained with advantage; out this kind, from its dense growth and fine broad silver leaf-margin, is peculiarly adapted for producing a fine effect by the beauty of its foliage alone.

The select Pelargoniums which I have thus described are all varieties of sterling merit, and they are certainly a great advance upon most of our best-known and most popular bedders. To prove the merits of his own kinds thoroughly, Mr. Pearson has introduced beds of such well-known kinds as Stella, Lady Constance Grosvenor, Blue Bell, and others, and I was amused

to see the poor appearance which even Stella presented alongside the Chilwell varieties. I do not doubt if Mr. Beaton had lived to see varieties so greatly surpassing his own pet sort, he would have been among the first to accord them his hearty admiration. Although planted near the best kinds which I have named, yet a bed of Violet Hill was as effective here as elsewhere, and this, to my mind, tends more than anything else that has been said in its favour to stamp it as a first-class bedder.

All these Pelargoniums were planted on the lawn near Mr. Pearson's residence, each kind filling a circular bed of sufficient size to give a good mass of colour, so that one was able to judge very fairly of their merits and fitness for the flower garden. These beds were not all together, but were dispersed among the fine masses of Rhododendrons and beautiful specimen Conifers which are the permanent occupants of this pleasant lawn, and they have grown into beauty under the hands of the present owner during the past twenty years. A fine Wellingtonia is about 30 feet high, and in perfect health and vigour. Mr. Pearson attributes this principally to the bed of very deep rich soil in which it is planted, and it is his opinion that the chief cause of decay in so many fine young Wellingtonias is because a suitable provision is not first of all made for the perpendicular or tap roots which force their way so deeply into the soil, and as this tree depends very much upon such roots for its sustenance, it is but reasonable to suppose that a shallow soil would quickly become exhausted. This is worthy of attention, for it would be a fallacy to suppose that those huge trees still flourishing in the primeval forests of America ever attained their gigantic proportions by the aid of mere surface roots; and, therefore, if succeeding generations in our own land are to see our native timber trees dwarfed by mighty Wellingtonias, too much attention cannot be given to the selection of the best situation and careful preparation of the soil. The plant to which I allude above was, when planted in its present position in 1860, only 1 foot high.

Another point in the culture of Conifers on which Mr. Pearson lays great stress, is the planting of the trees in their permanent stations when quite young, as he is able to demonstrate that small healthy young trees not only acquire the handsomest proportions, but by their more vigorous growth they soon beat those large specimens which have been transplanted so often before occupying their permanent quarters. Among the many fine examples growing on the lawn here, there are very fine specimens of *Cupressus macrocarpa*, the branches of one having a spread of 18 feet in diameter at the base, while the plant cannot be more than 14 or 15 feet high. *Cupressus Lawsoniana* was also fine, its pendulous shoots giving it a very graceful appearance. This and numerous other species were all well furnished with branches downwards to the turf, and as good lower branches are among the principal attractions in this class of trees, the mode of culture followed here appears to be the right one. In some instances where the young trees did not produce lower branches in sufficient quantity, cutting off the leading shoots has proved an effectual remedy. By this somewhat startling operation the vigour of the tree is almost entirely thrown into the side branches for a year or two, and in time a sturdy leader is again formed, growing so erect as to render it a difficult matter in a few years to discover its starting point. A beautiful specimen of *Picea Nordmanniana* was pointed out to me, the leader of which was accidentally cut off some years ago, and it is now as handsome a specimen as any on the lawn, with a particularly dense mass of lower branches resting on the turf, from whence it tapers upwards in most elegant proportions.

A few good beds of Cannas near the margin of the lawn were noteworthy from the agreeable effect which their foliage had when thus contrasted with that of the Pinuses.

Passing from the lawn we at once come to the glass houses, twenty-one in number, nearly the whole of them being of the span-roof form, and many of them being really magnificent structures of noble proportions, of great strength, and yet, from the judicious use of iron pillars and ties, they have a light and elegant appearance. They were built by Mr. Foster, of Beeston, but the elaborate details are, I believe, the joint conception of Mr. Pearson and Mr. Foster. Nothing appears to have been overlooked in the building of these houses; the ventilating apparatus is as simple as it is effective, and I saw many ingenious appliances, the usefulness of which I could not but admire. One novel feature was that of the form of the glass; the ends of the panes, which lap over each other, instead of being cut straight or at right angles with the sides, had a

semicircular outline, and thus the moisture from evaporation inside the house, instead of gathering along the edges of the glass and dripping on the plants beneath, runs down the centre of the panes in a single stream. Another plan for the avoidance of drip was that of a broad groove along each side of the roof bars holding the glass, which thus had concave sides instead of the usual flat surface, by which means any accumulation of moisture on the woodwork runs downwards to the front or sides of the house.

The houses and their contents were alike interesting; one, an orchard house 90 feet long by 30 wide, contained a remarkably fine healthy stock of Peaches and Nectarines in pots of all sizes and heights; a number of very large standard Peach trees planted in one of the borders had been cropping heavily, and there was still enough fine fruit remaining to convince one of the excellence of the entire crop. A few Vines, trained at intervals along the iron rods used to strengthen the roof, had an agreeable effect. Another orchard house contained an equally fine batch of pot trees all in a flourishing condition; here, too, were a number of standard trees bearing fine crops. The sight of the trees leads to the conviction that where the houses are lofty enough, Peaches may be grown so with much less care, and with results quite equal to that of any other more laborious method.

The pot Vines at Chilwell are a grand sight. They are grown principally in two span-roofed houses, one 60 feet by 20, and the other 100 feet by 24. They were all in splendid condition, forming such a collection of noble, well-ripened canes as is very rarely to be met with. The collection of sorts is good, comprising all the leading varieties. Another of these fine houses, intended eventually for a Fig house, was filled principally with Figs and a variety of standard fruit trees in pots.

The grand viney, of which a section is figured in Mr. Pearson's book on Vine culture, is 100 feet long by 24 wide. The entire length of one side is taken up by seedling Vines, which form a most interesting sight from the varied appearance of the foliage, a sure sign, in Mr. Pearson's opinion, of success in the operation of impregnation, which is well known to be a work of great difficulty, requiring much skill and watchfulness on the part of the operator, owing to the peculiar structure of the flowers of the Grape Vine. Among these seedling Vines was a plant of *Ferdinand de Lesseps*, raised by Mr. Pearson, and awarded a first-class certificate by the Fruit Committee at South Kensington. This is the most distinct and remarkable Grape of modern introduction. The berries are of a fine golden amber, but it is the full rich Strawberry flavour that renders this variety so remarkable, and I am confident that there is no one caring for Grapes at all but who, after tasting this delicious sort, would wish to grow it. From what Mr. Pearson told me of its hardiness and vigour, it is likely to thrive in a cool viney equally with the Black Hamburgh, and if this prove to be the case it will be an acquisition indeed. On the opposite side of the house were a number of young Vines bearing some magnificent fruit, among which were some grand bunches of Muscat of Alexandria, equally fine in bunch and berry, and thoroughly well finished. Bowood Muscat, Black Hamburgh, and Muscat Hamburgh were also fine; an extraordinary, but by no means handsome, bunch of the latter kind had such wonderful shoulders that I measured it, and it was actually fully 2 feet across. Mrs. Pince, too, was very fine, and Mr. Pearson spoke very highly of it. Frankenthal, or Victoria Hamburgh, was equally good, with berries of a large size.

The conservatory is a fine house, filled principally with a healthy stock of Camellias all growing in a pure turf soil. Among the miscellaneous plants, *Pelargonium echinatum* with its clusters of pretty white flowers, having a crimson blotch on the upper petals, was an attractive object; this fine old species is most useful to cut from; its sprightly flowers would have a charming effect in a bridal bouquet.

Another long, low, span-roofed house was filled with plants of the famous Long Gun Cucumber, growing on a trellis; they were in pots, which were plunged in cocoa-nut fibre, into which the roots had penetrated on all sides, apparently very much to the benefit of the crop, which was a very fine one.

The two long ranges of span-roofed pits struck me as being the most admirable structures of the kind that I have seen; great utility and simplicity are their leading characteristics. A description of them has already been published in "our Journal" by Mr. Pearson, but as it is probable that their full value is far from being understood, I will give a slight sketch of them. A low 9-inch wall forms the sides and ends; half the width of the

top of this wall is taken up by the plate on which the roof rests, thus leaving space enough inside for the 4-inch pipe which runs along each side. The sashes or lights, which are on hinges, do not meet at the apex of the roof, but a space wide enough for thorough ventilation is left by attaching the sashes on each side to a separate bar or plate. The opening along the top of the roof is covered by a moveable wooden cap, which is raised and lowered throughout its entire length by simply turning a wheel. To say that the lights are hung on hinges is not strictly correct, for there are no hinges at all in the true sense of the word, but two small hooks or angle irons are attached to each light, one on each side at the top, and when the lights are in their proper positions, the hooks fit into grooves or little semicircular pieces of iron which are sunk in the top bar, and so the lights can be raised or lowered with as much facility as if they were hung on real hinges. Moreover, by this simple contrivance each light can be lifted off at pleasure, and all annoyance from stiff or broken hinges is avoided. The body of the pit is filled with cocoa-nut fibre in which the pots are plunged. I need hardly point to the numerous uses to which these capital structures may be applied at all seasons of the year; from their lightness, simplicity, and great practical usefulness, they are certainly very superior to the old style of pit, with its costly high-raised walls and heavy sliding sashes.

The general nursery stock was in a healthy and flourishing condition; it consisted of the usual varieties of Conifers, fruit and forest trees, and shrubs. The soil of the various quarters of the nursery among the young stock is kept free from weeds, by allotting the work to the men at a stated sum per acre, for which the surface has to be kept thoroughly clean and well stirred throughout the growing season. This plan not only acts as an incentive to the labourers to earn all they can, but it also develops their intelligence sufficiently to enable them to see the wisdom of never trampling on a weed after it is hoed-up.

By the kindness of Mr. Pearson I was enabled to see something of the famous Chilwell orchards, of which I believe there are seventy acres; as most of the trees were laden with a heavy crop of fruit, it was an extraordinary and interesting sight. I noticed several handsome trees of the Bess Pool Apple, but the most attractive and showy fruit that I saw was Duchess of Oldenburgh Apple, a very handsome striped kitchen fruit, which, ripening early, most command a much better sale than such pale-skinned kinds as Keswick Codlin and Hawthornden. It is a heavy cropper, and its fruit grows to a large size. A number of dwarf Plum trees had heavy crops of fruit; they consisted principally of those excellent hardy kinds, Denyer's Victoria and Prince Englebert. Large numbers of trees of the Shropshire Dimson had a heavy crop of fruit.

One other notable feature of these orchards is the numerous huge Pear trees bearing a full crop of fine fruit. Most of these trees some years ago had arrived at that tantalising state of barrenness with which all fruit-growers are familiar; but instead of destroying them after the usual fashion, Mr. Pearson had the whole of the branches cut off, not close to the stem, but a long way from it. They were grafted with useful kinds which have flourished so vigorously that without looking closely it is difficult to see the junction of stock and scion, and ever since this operation the branches resulting from the grafts have been most prolific.—EDWARD LUCKHURST.

INQUIRY.

HAVING answered an advertisement which appeared in THE JOURNAL OF HORTICULTURE of July 21st, by Wm. Dillistone, Nurseries, Sible Hedingham, Essex, in which he offered twelve double Pelargoniums for 6s., which sum I sent to the above address in stamps on the 4th of August, I wrote again on the 13th ult., but still no reply. I wrote to the General Post-office, and the reply is that my letters were duly delivered. The Post-office authorities state that Mr. Dillistone left Sible Hedingham on the 17th ult. Can you inform me of his whereabouts?—S. T. FOSTER, 13, Washington Road, Sheffield.

ABUNDANCE OF MUSHROOMS.—Have any of your readers noticed the extraordinary crop of Mushrooms there has been this year? I have never witnessed anything like it; for the last three weeks the fields about here have been covered with them. I gathered this evening six of the largest I have ever seen or heard of; one of them measured 8 inches in diameter;

the stalk was about 7 inches high. Is not this size rather unusual?—AN OLD SUBSCRIBER, Co. Dublin.

[We never saw such abundant natural crops of Mushrooms as we have seen on the pastures this year in Northamptonshire, Sussex, and other counties.—EDS.]

METROPOLITAN FLORAL SOCIETY.

I HAVE to thank "L. W." for his kindly and cheery words, they are, I rejoice to say, but echoes of many others which I am continually receiving; and amidst the difficulties which have attended the starting of a new Society, I have been greatly helped by the words of those whom I have never seen, and who know me only as a scribbler or brother "maniac."

With regard to the future of our Society, we have considered that it would be very unwise to risk everything in holding independent exhibitions, which might prove failures and cripple our exertions; we, therefore, adhering to our original programme, mean with the liberal assistance of the Crystal Palace Company, to hold an annual autumn show there; this will take in three of the flowers named—the Dahlia, Gladiolus, and Hollyhock. We have already made overtures to the Royal Horticultural Society to offer special prizes in April for Auriculas, and in July for Carnations and Picotees, the arrangement of these prizes to be left to us, and to be regulated by the amount of support we shall obtain. We have not yet determined what course we shall adopt with regard to the Pansy, Pink, Ranunculus, and Tulip, but it will probably be to offer prizes for them in the same manner at the Crystal Palace exhibition in May and June. I need not, I hope, say that in all this we shall act entirely independently, and shall endeavour to do our best to advance the interests of our favourites, having, so the Committee has decided, especial reference to amateurs. We are preparing a report of our proceedings, which I shall be happy to forward to "L. W." and any other friends, and I am prepared now to receive the names of anyone who may desire to join us. Our motto must be *Amor omnia vincit*; love of our flowers, and brotherly love to one another.—D., Deal.

THE FLOWER SERMON.

I AM glad to observe that you have extracted, at page 208, a short account of the flower sermon. I beg permission to make a correction in it. The plant found by Mungo Park in Africa was not a blue flower but a Moss, which bears no real flowers. He brought it home with him, and it was ascertained by his brother-in-law, James Dickson, of Covent Garden, the eminent cryptogamist, to be the *Picranum bryoides*. It is abundantly produced in our hedgesides and by sides of newly cut ditches in spring. It is figured in plate xvi. of Hooker and Taylor's "Muscologia Britannica," second edition, London, 1829.

Dr. Whittemore was entirely ignorant of Fairchild's bequest when he commenced his annual flower sermon. Whether such sermons are still delivered in Shoreditch Church I know not. Jones, of Nayland, delivered some of them, and I should be glad to learn if either his or any of the others have been published as some of the Boyle lectures have been. All honour to Dr. Whittemore, who began his interesting discourses *proprio motu*.—A CONSTANT READER.

WATER CRESSES GROWN OUT OF WATER.

I WISH to tell that one of your contemporaries is wrong in saying that Water Cresses not grown in water are not fit to eat. Six-pennyworth of seed having been sown at Stanmore Lodge, Penge, last spring, in a few weeks we had plenty of Cresses, and we have had enough for the family ever since. The value, at the lowest, would be 2s. per week, and this off about 4 square yards of ground. So far from the plants standing in water, they stand about 6 inches above the level of the ground. The Cresses are excellent.—S. HATCHING, Maple Road, Penge.

MISTLETOE ON THE OAK.—The extreme rarity of well-authenticated examples of the parasitism of the Mistletoe on the Oak has induced Dr. Bull, of Hereford, to collect the known instances, which he finds to be eight in number—viz., three in Herefordshire, and one each in Gloucestershire, Monmouthshire, Devonshire, Hants, and Surrey. In the most recently discovered instance, in the Forest of Deerfold in Herefordshire,

the Mistletoe was found on an Oak of the species *sessiliflora*, some fifty or sixty years old; it is a female plant, growing high up on the main stem, and forming a large spreading branch with a diameter of 3½ feet, and springing from the Oak in a single stem nearly 4 inches in circumference. The Mistletoe also grows on a Thorn close by, and has probably sprung from a seed dropped by a bird from above.—(Nature.)

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 21ST.

THERE was on this occasion an excellent show of novelties, although the subjects specially invited in the floral department were but poorly represented as regards numbers, and were but fair in quality. On the other hand the Fruit Committee had their hands full. On the whole the meeting sustained the good character of its predecessors, and, though a large attendance could not be expected at this season, there was a fair sprinkling of visitors.

FRUIT COMMITTEE.—G. P. Wilson, Esq., F.R.S., in the chair. Mr. William Paul, The Nurseries, Waltham Cross, sent a number of seedling Grapes; many of them were very excellent, but none sufficiently meritorious to receive any special award. Messrs. Lane & Sons, Great Berkhamstead, sent a magnificent collection of fifteen varieties of Grapes, some of them very large and fine, to which a special certificate was awarded. Mr. Clarke, gardener to J. Brown, Esq., Holmshush, Horslam, sent three fine bunches of Black Alicante Grapes, beautifully coloured but quite acid. Mr. Webb, Calcot, Reading, sent a basket of Black Hamburg Grapes, grown in the open air. Mr. Rochford, market gardener, Page Green, Tottenham, sent a fine example of Charlotte de Rothschild Pine Apple, weighing 9 lbs., but it was scarcely ripe. Mr. Perry, Algar Kirk, Spalding, sent some seedling Grapes which were considered simply Black Hamburgs.

Mr. G. Goldsmith, gardener to G. D. Fryer, Esq., Hollenden Park, Hildenborough, sent a dish of remarkably beautiful Peaches, named Coupe d'Hebe. They somewhat resembled Bellegarde. The variety was not known. Mr. Goldsmith further exhibited a dish of Late Duke Cherries. Mr. Smith, gardener to the Earl of Gainsborough, Exton Park, Oakham, sent some examples of Prince of Wales Nectarine, a fine late variety.

Messrs. Wheeler & Son, nurserymen, Gloucester, sent examples of a seedling Pear, named Brockworth Park, which greatly resembled Louise Bonne of Jersey, but it was much larger and finer. It was awarded a first-class certificate. Mr. Tillery, of Welbeck, sent some examples of Williams's Bon Christian Pears, also examples of a fine large seedling Apple. Mr. Hurdley, gardener to E. J. Weld, Esq., Lutworth Castle, Dorset, sent examples of a large green kitchen Apple. Mr. W. Reid, Sydenham Hill, Kent, had examples of a small flat Russet dessert Apple.

Mr. Gilbert, gardener to the Marquis of Exeter, Burghley, Stamford, exhibited examples of two enormous hybrid Melons. One named General Molke weighed 9 lbs.; the other, Princess Louise, weighed 15½ lbs.; excepting for great size, which is not required, these were in no way remarkable. Mr. W. Paul sent a box containing about thirty varieties of Apples, to which a special certificate was awarded. Mr. Gilbert exhibited good examples of Cox's Golden Drop and Reine Claude de Ravay Plums. Mr. Eckford, Coleshill, again submitted his seedling Nectarine. Mr. Penn, Woodstock, exhibited some interesting examples of Apples, showing the effect the stock has upon the scion. Ribston Pippin grafted on the Blenheim Pippin had quite lost its character, being so different both in appearance and flavour that no one could have recognised it. Mr. Penn also submitted a pie made from the fruit, but it was too much sweetened.

Mr. Penn exhibited a very large and interesting collection of Potatoes, showing the results produced by grafting to be in every instance to deteriorate instead of to improve. The true Milky White was exhibited cooked, also the same sort grafted on the Fluke. The latter was inferior to the former. A special certificate was awarded to Mr. Penn for his excellent and interesting collection. Messrs. J. C. Wheeler & Son sent some very fine examples of a green Cos Lettuce, named Highnam Court. Messrs. Carter & Co. contributed some good examples of Giant Rocca Onion. Messrs. Veitch & Sons, Royal Exotic Nurseries, Chelsea, had a large and fine collection of Beetroot, examples of which were cooked for the Committee. A special certificate was awarded.

M. Verhulpen, of Brussels, exhibited Bonckart's Patent Fruit-gatherer, a very ingenious instrument for gathering Pears and Apples on high trees without the necessity of ladders to get at them. This, which we shall notice more fully afterwards, was greatly approved by the Committee, and was awarded a first-class certificate.

Prizes were offered by H. Bohn, Esq., for Peaches grown on standards in the open air, for which there was one exhibition. The Committee, however, believed the fruit had been grown on walls, and consequently withheld the prize. A prize was also offered for a collection of Tomatoes, for which Messrs. Carter & Co. exhibited a very extensive collection of varieties both in pots and as cut fruit; to these the first prize was awarded. For the best dish of dessert Pears the first prize was awarded to Mr. Douglas, Loxford Hall, for Cox's Orange Pippin; the second was awarded to Mr. Craddock, Compton Verney, Warwick, for the same. For the best dish of Pears the first prize was

awarded to Mr. Smith, gardener, Exton Park, for Benrre d'Amanlis; the second prize to Mr. Craddock, Compton Verney, for Louise Bonne of Jersey.

FLORAL COMMITTEE.—Mr. J. Fraser in the chair. From Messrs. J. Brooke & Co., Fairfield Nursery, Manchester, came a magnificent new Dendrobium, named *D. chrysois* by Professor Reichenbach. The flowers of this were about 3 inches in diameter, and of a rich yellow, the lip beautifully fringed, and of the same colour, but with two dark purple blotches at the base. To this a first-class certificate was awarded.

Messrs. Veitch, of the Royal Exotic Nursery, Chelsea, sent a numerous and very fine collection of Orchids and Pitcher Plants. Among the former were splendid examples of *Odontoglossum grande*, the brilliant *Masdevallia Veitchii*, *Vanda Bensonii*, *Pescatorea cerina*, *Cypripedium Harrisianum*, *C. concolor*, several fine varieties of *Cattleyas*, *Lalia elegans*, and *Sobralia macrantha* in beautiful condition. The *Nepenthes*, or Pitcher Plants, were magnificent specimens, some of them with upwards of two dozen pitchers. They consisted of *Nepenthes Domitiana*, *Rafflesiana*, and *Hookeri*, each with large and finely-marked pitchers, *N. hybrida*, and *N. hybrida maculata* with a multitude of pitchers, blotched with dark red. A special certificate was awarded the collection. Messrs. Veitch also exhibited Brazilian or Chilian Beet, with most brilliant-coloured leafstalks, and Dell's Crimson, well known by its compact, finely-coloured tops, whilst the root is excellent for culinary purposes.

Mr. B. S. Williams, of Holloway, also sent a fine collection of *Odontoglossum grande*, together with *Cypripedium Stonei*, *Phalænopsis amabilis*, and the pretty pink and white *Oncidium ipcurvum*. A special certificate was given for the collection.

From Messrs. J. & C. Lee came a collection of Orchids and fine-foliaged plants. Among the Orchids was *Dendrobium catheolae*, with a profusion of orange yellow flowers; and among the fine-foliaged plants were several very handsome Palms, such as *Livistonia rotundifolia*, *Cocos Weddelliana*, *Geonoma Verschaffeltii*, *Areca Verschaffeltii*, and *Chamadorea graminifolia*. The last is an elegant Palm for a basket, in which way it was exhibited. A special certificate was awarded. From the same firm came Mrs. John Lee, a most beautiful Gold and Bronze Pelargonium, with a deep rich-coloured zone. This had been grown in the open ground, and well deserved the first-class certificate awarded it. Along with this was Edward Milner, a Golden Tricolor, likewise lifted from the open ground. *Livistonia altissima*, forming part of the collection of Palms, received a first-class certificate.

Messrs. E. G. Henderson, St. John's Wood, contributed a collection of tree Carnations; dwarf Asters; Golden and Silver Tricolor Pelargoniums, very fine; *Hydrangea japonica speciosa*, a handsome white variegated sort, which had before received a certificate; *Thymus citriodorus aureus*, a pretty dwarf golden-leaved variety; and *Alternanthera magnifica*, a finely-coloured bronze and rose variety. To each of the two last-named a first-class certificate was given, and special certificates were awarded to the collections of tree Carnations and Tricolor Pelargoniums. *Cineraria splendens*, with very ornamental silvery foliage, also received a first-class certificate.

Messrs. Ivery & Son, Dorking, exhibited a numerous collection of early British Ferns, and likewise a number of new varieties, of which *Scolopendrum vulgare Iveryanum*, *S. vulgare lacerato-cristatum*, and *Polystichum angulata congestum*, were awarded first-class certificates.

Mr. W. Paul received a special certificate for four boxes of cut Roses, very fine for this time of year, and accompanying these were fine Asters and cut blooms of Zonal Pelargoniums. Mr. W. Paul likewise exhibited Silver Tricolor Marchioness, with a broad white edge, a very promising variety, which requires, however, to be seen in better condition.

Mr. Thomas Hobbs, Lower Easton, Bristol, had a first-class certificate for self Dahlia Annie Hobbs, white, and a second-class certificate for Robert Lambert, dark maroon. Mr. Rawlings, Romford, had a like award for George Peabody, a well-formed maroon flower. Rev. C. Roe, Welnetham Rectory, Eury St. Edmunds, exhibited Suffolk Gem Dahlia, in the way of Stafford's Gem. Gem of the Grove, a beautiful flower of the same character, but finer, had a first-class certificate; this came from Mr. Harris, Orpington. Second-class certificates were given to Mr. Keynes for Victory, maroon self; James Cocher, ruby, with a mauve tinge; and Flossy Williams, fancy, white, streaked and dotted with lilac; while Mary Keynes, cream tipped with purplish rose, had a first-class certificate. A similar award was made to Mr. Eckford, gardener to the Earl of Radnor, Coleshill, for seedling Verbena Peter William, scarlet with a large white eye, and large pips. Mr. Eckford sent several other fine seedlings. Mr. J. Douglas, gardener to F. Whitburn, Esq., Loxford Hall, Htord, sent seedling Gladiolus John Standish, a magnificent pale blush flower, having a small bright purple feather in the lower divisions. For this a first-class certificate was given.

Messrs. Stuart & Main, of Kelso, sent a number of blooms of seedling Pentstemon; and Mr. Porter, gardener to E. Benham, Esq., seedling Pentstemon.

Mr. Anthony Waterer, Knap Hill Nursery, Woking, was awarded a special certificate for beautifully grown plants of *Cupressus Lawsoniana erecta viridis*, forming fine pyramids; and accompanying these were *Cupressus Lawsoniana gracilis*, which is of a drooping habit, and a

basketful of a *Rhododendron* called *cheiranthifolium*, with very small narrow leaves.

Messrs. Standish & Co., of the Royal Nurseries, Ascot, were awarded a special certificate for a group of hardy shrubs, consisting of *Aucubas*, *Euonymus*, *Osmanthus*, *Janiperus*, *Retinosporas*, and *Cupressus nootkatensis variegata alba*, which, with several other of the variegated forms, was very effective. *Skimmia oblata* with its bright scarlet berries served to enliven the collection.

From Messrs. Lane came a seedling variegated form of *Cupressus Lawsoniana*.

Mr. Green, gardener to W. Wilson Saunders, Esq., Hillfield, Reigate, sent a small collection of Agaves, of which *A. Besserianna candida* with glaucous leaves had a first-class certificate. Mr. Green likewise exhibited *Gloxinia insignis*, and a very fine spike of *Acineta Barkeri*.

To Mr. Parsons, gardener to W. J. Blake, Esq., Daneshury, a first-class certificate was given for a pretty variety of *Athyrium Filix-femina* named *Blakei*.

Prizes were offered for twenty-four cut blooms of Asters. There were only two exhibitors—viz., Mr. J. Walker, nurseryman, Thame, and Mr. J. George, gardener to Miss Nicholson, Putney Heath, who received first and second prizes respectively. In the next class for twelve blooms there was more competition, stands coming from Messrs. E. G. Henderson, Mr. Walker, Mr. George, and Mr. Porter, gardener to E. Benham, Esq., Isleworth. The last three exhibitors took prizes in the order in which their names occur. In the different collections several very good blooms were shown, and the colours bright and well varied. All the blooms were French Asters with the exception of the first-prize twenty-four, in which there were a few quilled varieties.

Prizes were likewise offered for double Zinnias of six colours. The best came from Mr. Walker, the second best from Mr. Porter, but neither collection was up to the mark. In Stocks and Begonias there was no competition.

GENERAL MEETING.—Major R. Trevor Clarke in the chair. After the usual preliminary business, the Rev. M. J. Berkeley directed special attention to *Dendrobium chrysotis*, which, he said, bore a close resemblance to *D. fimbriatum*, and although the two differed in the spotting of the lip, and *fimbriatum* came from Nepal, while *chrysotis* was from Assam, yet those who were in the habit of studying plants would be inclined to think the two the same. *Gloxinia insignis* from Mr. Wilson Saunders's gardener was next noticed as very pretty, and as being known sometimes as *G. maculata*. Major Trevor Clarke had brought a flower of the true *Fuchsia coccinea*. The plant which had passed under that name was *Fuchsia magellanica*. Mr. Berkeley then read the following account of it given in the "Botanical Magazine," vol. xciv., t. 5740:—

"It will surprise many of our horticulturalists to learn that the plant now called *Fuchsia coccinea* in our gardens is not the first described species of that name, though it has borne it almost exclusively from within a year or two of the introduction of the real plant; and it may still more surprise them to know that the original *F. coccinea* is very rarely seen in cultivation. There is a story current amongst gardeners that the common *Fuchsia* was, when originally introduced, a greenhouse plant, but that it has become so far acclimatised as to withstand, without protection, the coldest winters of many parts of England, Scotland, and Ireland, and the milder winters of all Great Britain: be this as it may, it is not doubted that the *Fuchsia coccinea* was once treated as a stove or greenhouse plant, and now it thrives both in a greenhouse and out-of-doors. Now, when the true *F. coccinea* has changed its habits no one can say, for next to nothing seems to be known of its history between the date of its introduction as a greenhouse plant in 1788, and its re-discovery in the greenhouse of the Oxford Botanic Garden in 1877; the fact being, that the much harder *F. magellanica* was imported from wintry Terra del Fuego very shortly after the introduction of *F. coccinea*, and immediately usurped its name and spread it to every garden in the kingdom, whilst the true plant lingered in botanic gardens, lastly surviving (greatly to the credit of the Baxters, father and son) in that of Oxford alone. It may be more common abroad, and is almost naturalised in Madeira, according to Maudon.

"The native country of the true *coccinea* is unknown; it is probably Brazilian, as it resembles the Brazilian more than the Western or Southern American species; Salisbury says it was introduced by Vandell from Brazil, whereas Aiton attributes its introduction to a Captain Frith, from Chili.

"The evidence of the plant here figured being the true and original plant of Aiton's 'Hortus Kewensis,' ed. 1, rests on the fact that named specimens of the same are preserved in the Banksian Herbarium of the British Museum, and in Sir J. Smith's Herbarium at the Linnean Society, all procured at Kew in the year of the introduction of the plant, and at the date of its being described by Aiton.

"As a species, *F. coccinea* is much more graceful than any of the varieties of *F. magellanica*, flowers even more freely, and is readily distinguished by the almost sessile leaves with broad bases, and the lridy twigs and petioles; further, its foliage turns of a bright crimson when about to fall."

The new pest which had attacked the Vine was the next subject to which attention was directed. It was a pest which would almost be destructive to cultivation if spread as widely as the mildew, and in some cases it had done hundreds of pounds of damage. In 1867 he was at Lord Powerscourt's at Enniskerry, and Mr. Donn, the intelligent gardener there, pointed out to him (Mr. Berkeley), Vines affected by this insect, *Phylloxera vastatrix* (See vol. xvii., pp. 45, 46, where a description and figures of it are given). At first it seemed probable that the insect attacking the roots might not be the same as that on the stems, but he had come to the conclusion that the two were the same. He might say that Mr. Donn had discovered the only method

of destroying the insect, a plan which had proved perfectly successful. This consisted in taking the Vines up, removing all the soil from their roots, washing these three times in pure water, and then replanting in fresh soil. The winged male insects figured by Planchon, so far as he knew, had not been seen in this country, and it would be a great—in fact, a national, service, if anyone who saw them would forward specimens to Mr. Andrew Murray at the South Kensington Museum. Mr. Fenn's collection of Potatoes, particularly as showing the results of grafting, and the effects of the same operation as regards the Ribston Pippin Apple and the Blenheim Pippin, which have before been fully described in our pages, were then noticed; and, passing to the Tomatoes, Mr. Berkeley said, however good they were as a sauce, they made an excellent salad if cut in slices, and mixed with Water Cresses, a *sorquet* of Garlic or Shallots, a little oil, and plenty of vinegar. In conclusion, he reminded the meeting that on October 5th prizes were offered for collections of edible and poisonous Fungi.

Mr. Marshall kindly offered pollen of *Nepenthes Rafflesiana* to anyone who might be desirous of attempting hybridisation with these interesting plants.

BEDDING PLANTS IN 1870.

(Continued from page 179)

I WILL continue my remarks on bedding Geraniums by referring next to those that are grown for their foliage and not for their flowers.

To commence with the Tricolors, I still think Mrs. Pollock nearly as good as any for general effect. It is, no doubt, surpassed by many in regularity of outline as regards the zone, but I do not think our old favourite will be easily discarded. Lady Callum has a much darker zone, and a more brilliant colouring in the red of the zone, and is especially good in the spring and again in the autumn, but the colour, owing perhaps to the darkness of the zone, seems more bright in the height of the summer than either in Mrs. Pollock or Sophia Dumaresque. The latter and Flambeau, a variety sent out by Messrs. Backhouse, of York, and exceedingly like it, are both very effective bedders, with a more spreading habit than Mrs. Pollock.

Lady Headley and Attraction are both very beautiful wherever I have seen them, but I have not tried them as yet myself, but have seen none equal in colouring to Mrs. Headley as yet. Edith Pearson, a variety sent out by Mr. Pearson, of Chilwell, has a very soft and pleasing effect in a bed, but is surpassed by another variety of his, William Sunday, which I think he has not sent out as yet.

If we may judge from plants in pots, Prince of Wales, Mrs. Dunnett, and Fairland, varieties sent out by Messrs. Carter and Co., of High Holborn, are likely to be great acquisitions in the flower garden; and so is Ealing Rival, raised by Mr. Stevens, of Ealing.

Of these I have tried this summer (besides those I have previously mentioned), as Lucy Grieve, Sophia Casack, Louisa Smith, Queen of Tricolors, Lurline, and Spanish Beauty, I much prefer Lucy Grieve as one of the very brightest-coloured varieties I have yet bedded out, the red of the zone being very distinct, and lasting a long time before it fades. Louisa Smith has too much yellow, but is good in other respects. Spanish Beauty, on the other hand, is too dark, and Queen of Tricolors has orange instead of red in the zone.

Of the Silver Tricolors I cannot recommend any for bedding purposes. For pot plants I like Italia Unita, Pieturata, Caroline Longfield, Mabel Morris, and Mrs. John Clutton.

Of Golden-variegated varieties, as Golden Chain, Cloth of Gold, Crystal Palace Gem, &c., I still think, where it will grow, that none equals in point of colouring the old Golden Chain; it requires, however, manure and liberal treatment. Crystal Palace Gem turns too green with me; I have seen it very good elsewhere, but a self yellow-leaved sport from it has kept its colour better.

There are several self-coloured Golden varieties now, but much the best with me is Pillar of Gold; the leaves die off a lighter colour instead of turning green, and the young fresh leaves as they open are nearly pure gold; a line of it which I have under my windows in front of the house is very striking now. It is a good grower under proper treatment, but will not stand neglect.

Of the White-margined section I still like Flower of the Spring as much as any; it has such a compact habit, and fills the beds so well with the foliage. Miss Kingsbury is very good, but I do not see any great improvement, as I do not like the colouring of the green in the leaf so well, and the margin is not so wide and so well defined as in Flower of Spring. Alma is a desirable variety for larger beds. Bijou, though very white, has too upright a habit. Mrs. Lennox and Mountain

of Light are both very good in point of colour, but delicate in habit.

Of those I have not tried, but seen elsewhere, I prefer Mr. Turner's May Queen, an exceedingly effective variety, and Waltham Bride and Avalanche, which have the advantage of white flowers.

I turn next to the Bicolor or Gold and Bronze section, which in the hands of Mr. Laing, at Stanstead Park Nursery, made such rapid advances last year; and though we hear very conflicting statements as to their merit in the flower garden, yet I anticipate that when such sorts as *Impératrice Eugénie*, *Crown Prince*, and *Brilliance* become better known they will be largely employed. I have tried a great number of sorts this year—*Beauty of Oulton*, *Beauty of Calderdale*, *Model*, *Princess Alice*, and one or two others raised by Mr. Willis; *Ebor*, Messrs. Backhouse's; *Egyptian Queen* (Carter); *E. G. Henderson*, Mrs. J. Todd, Duke of Edinburgh, *Her Majesty*, *Golden Sceptre*, and *Bronze Queen*, most of which, I believe, were sent out by Messrs. Henderson; and *Kentish Hero*, *Black Prince*, *Brilliance*, *King*, *Charming*, *Countess of Kellie*, Mrs. Allan Lowndes, *Fairy Ring*, *Princess of Wales*, Mrs. Lewis Lloyd, and one or two others of Messrs. Downie, Laird, & Laing's. I begin by discarding all those that have too much tendency to turn green and have too much dark brown in the zone, as they run far too near in colouring to the old dark-leaved Zonals, as *Baron Ricasoli*, *Striking*, *Symmetry*, and others, and I select those that have true gold margins and discs with red or red-bronze zones. Of these *Impératrice Eugénie* is the brightest in point of colouring, and the leaves instead of turning green die-off a lighter colour, so that the effect from a distance is very brilliant. *Crown Prince*, Mrs. Allan Lowndes, and *Brilliance* approach nearer to *Impératrice Eugénie* in point of colour than any others, and the first named, *Crown Prince*, has vigour of habit combined with brilliancy of colouring. Of those that are gold and bronze—that is to say, with less red in the leaf, I like *Kentish Hero*, Duke of Edinburgh, *E. G. Henderson*, Mrs. J. Todd, and *Charming*. *Beauty of Oulton* very soon turns green. *Beauty of Calderdale* is effective when just bedded out, but is coarse in its habit and loses its gold colour in the summer. *Black Knight* is too dark in the zone. But there is another section with very narrow zones, and a great deal of yellow on the leaf which is very effective, but it produces more the effect of a yellow bed. Of these the best is Mrs. Lewis Lloyd, *Princess of Wales*, and *Golden Sceptre*. The first has a dwarf spreading habit, and will be very useful as an edging plant. *Princess of Wales* has a stronger and more upright habit; and *Golden Sceptre* has a less distinctly-marked zone, the old leaves scarcely showing the zone at all, but it has a very golden effect.

There is one secret in the management, they require liberal treatment, and they should always be kept growing, as the leaves when they become old, with the exception of those of *Impératrice Eugénie*, *Crown Prince*, Mrs. Allan Lowndes, and *Brilliance*, lose their colouring. If they are liberally treated they will stand any amount of sun, but shade is fatal to them. This is true with regard to all gold-leaved plants, but the reverse is true with regard to the white-margined sorts.

While on the subject of Bicolor or Gold and Bronze Geraniums, I must protest against their being shown, as is so often the case at country shows, as Variegated Geraniums. Variegation implies a sport. All our Tricolors and white-edged Geraniums were green Zonals to begin with, but the Bicolors have not changed since they were seedling plants. The mere fact of having two colours in a leaf does not constitute a variegation, otherwise *Baron Ricasoli* or *Lady Constance Grosvenor*, or any Zonal that is not self-leaved might be shown as a variegated Geranium. I could pick leaves at this present moment from *Beauty of Oulton* or *Her Majesty* which no one would distinguish from an ordinary green Zonal. I cannot again see that a Nosegay Geranium ought ever to be disqualified for competition among Zonal Geraniums unless there is a separate class especially mentioned in the schedule for Nosegays. A Zonal *Pelargonium* is classified by the leaf and not by the flower, and several of the hybrid Nosegays approach so near in roundness of petal to those that are commonly called Zonals, that I defy anyone to distinguish them if the individual flowers were taken from the truss, but they are still easily distinguished when on the plant by the size and shape of the truss and habit of growth.

Let me add as a postscript that I really am exceedingly obliged to the young ladies of *Geranium Cottage*, Benlah, for the wish expressed that I could see their beds of *Bayard* and

William Underwood. I should like also to see the young ladies themselves, and then, perhaps, I might be able to persuade them that *Waltham Seedling* is not the rubbish they imagine. I am sure of one thing, that at the time of the Metropolitan Florists' Show at the Crystal Palace the beds of *Waltham Seedling* were far the best Geranium beds there; and if they could at present see *William Underwood* in my garden, growing within a few feet of *Waltham Seedling*, they would be obliged to own there was no comparison between the two, as there is as much bloom on a square foot of *Waltham Seedling* as on a square yard of *William Underwood*. I have said before in my notes on bedding Geraniums that *William Underwood* is the best Zonal I have tried, but, like all other Zonals, it is too upright in its habit; and though it produces a good effect by close planting, yet it does not last. I do not know what are the Geraniums which the young ladies class as others as useless. *Bayard* is undoubtedly good; *William Thomson* and *Douglas Pearson* I have, and appreciate. And now, as they wish to alter the planting of their garden, I will suggest another plan besides that mentioned by the "Old Gooseberries." As with only thirteen beds in a garden, I should make no two alike, in order to have more variety, which adds much to the interest of a garden, though I should match my colouring so as to cross-balance as nearly as possible:—

- 1.—Centre vase.—*Arunco Donax variegata*; edge, *Impératrice Eugénie* Bronze and Gold Geranium and Blue *Lobelia*, plant for plant. Centre of bed, *Centaurea ragusina*; edge, *Alternanthera amabilis*.
- 2.—Purple King *Verbena*; edge, Golden Feather *Pyrethrum*.
- 3.—Miss Wimsatt *Verbena*; edge, Golden Feather *Pyrethrum*.
- 4.—Mrs. Pollock; edge, *Iresine Lindenii*, planted closely and kept pinched.
- 5.—Lady Cullum; edge, *Amaranthus melancholicus ruber*.
- 6.—Miss Kingsbury.
- 7.—Flower of Spring.
- 8.—Bayard
- 9.—Douglas Pearson
- 10.—Amy Hogg
- 11.—Dr. Hogg
- 12.—Centre line, *Centaurea ragusina*; edge each side, Violet Hill.
- 13.—Centre line, *Ciccaria maritima*; edge each side, Duchess of Sutherland.

If these beds are wide enough to admit five rows of plants, edge one bed with dwarf kinds of Gold and Bronze Geraniums and the other with small plants of *Pillar of Gold* or *Cloth of Gold*.

If 6 and 7 are enlarged and altered, as the Editors suggest, I should plant one with *Rose Rendatler* edged with *Miss Kingsbury*, the other with *Maid Kent* edged with *Flower of Spring*. I have discarded *Madame Kundershoff* as not good enough to go with the rest of the plants they have named.—C. P. PEACH.

WINTER-BLOOMING ORCHIDS.—No. 8.

PLEIONE.

This is a small but extremely beautiful genus, which, as I remarked in my former article, is often included in the genus *Cælogyne*. Beside the minute botanical differences between the two genera, they differ considerably in general appearance and habit; moreover, they are all deciduous and produce their exquisitely-marked flowers in winter whilst destitute of leaves. The majority of the species grow at elevations of from 6000 to 8000 feet in the forests of Nepal, Sikkim, and Bhotan, clothing the trunks and branches of the trees, and when in flower are said to present a most gorgeous aspect, causing the woods to appear all ablaze. They are mostly grown in pots, but succeed equally well upon blocks; in the latter way they require more sphagnum about them than most plants grown in a similar manner. When grown in pots, which is undoubtedly the best method, they should have ample drainage. The soil should be fibrous peat, sphagnum moss, and rich leaf mould in equal parts, adding a small portion of silver sand, but the curious little pseudo-bulbs should not be elevated above the rim of the pot, as in the usual method of potting Orchids. During the growing season moderate heat and an abundance of moisture are necessary to the development of large strong-flowering pseudo-bulbs; after these are formed they may be removed to a cool house and kept tolerably dry until the flower buds begin to show themselves at the base of the old bulbs, when additional heat may be applied with advantage.

P. HUMILIS.—Pseudo-bulbs some 2 inches high, in shape like little flasks, of a rich green colour, tinged with purple. Leaves narrow, acuminate, and dark green, turning yellow and falling off soon after growth is complete. The flowers are produced

singly; sepals and petals linear-lanceolate, white suffused with pale rose; lip of the same colour, fringed at the upper part, and traversed by six fringed parallel lines; between each of these lines is a streak of rich crimson. This lovely plant

Pleione humilis.

is in full beauty in the very depth of winter, and no collection should be without it. Native of Nepal.

P. WALLICHIANA.—In this species the pseudo-bulbs are somewhat different from those of the preceding, being elevated into a narrow point at the top, dark green and beautifully spotted with purplish crimson. Flowers very brilliant; sepals and petals rich bright rose; lip plaited, toothed at the point, of the same colour as the sepals, streaked inside with white and yellow, and splashed with crimson. This is a more attractive kind than the preceding, flowering usually early in spring—that is, from February to April. Native of the Himalayas.

P. MACULATA.—The pseudo-bulbs are about 2 inches high, and of a uniform dark green, the leaves in all the kinds being nearly of the same size. Sepals and petals oval and acute, pure white; lip white, blotched with yellow in the centre, where there are several crested parallel lines, and streaked with crimson in front. The charming flowers of this species are produced late in autumn. Native of Khasia.

P. LAGENARIA.—This is a gem amongst gems. The pseudo-bulbs are distinct from any other species, being flask-shaped

Pleione lagenaria.

with a peculiar overlapping neck. The flowers are large and solitary; sepals and petals narrow, deep rose colour; lip very

large, waved at the margins, white variegated with yellow and rich purple. It flowers profusely during the depth of winter. Native of the Himalayas.

P. HOOKERIANA.—At present this is somewhat rare in cultivation and difficult to obtain true. The pseudo-bulbs are from 2 to 4 inches long, ovate, smooth, and in colour bright green. Its leaves are dark green, and remain perfect until after the blooming season, considerably enhancing its beauty and rendering it very distinct from all the other members of the genus. Flowers large; sepals and petals oblong and pointed, rich bright rose; lip white suffused with rosy pink. A most elegant plant, flowering during the late autumn and early winter months. Native of Sikkim at great elevations.

P. REICHENBACHIANA.—This is a species of recent introduction, and which I have not yet had the pleasure of growing; judging, however, from its native habitat, I expect a greater amount of heat will be necessary to develop its beauty than is required by species from cooler regions. The pseudo-bulbs are between 2 and 3 inches high, bottle-shaped, with an obtuse top; ground colour deep green beautifully netted with brown lines. Flowers upwards of 2 inches in diameter; sepals and petals pale rose margined with white; lip white streaked and spotted with light purple, and crested on the centre. It blooms late in autumn and early in winter, and was introduced to this country from the mountains of Arracan.—*EXPERTO CREDE.*

WORK FOR THE WEEK.

KITCHEN GARDEN.

Pay every attention to the autumn *Broccoli*, also to autumn and winter *Lettuces*, watering them with liquid manure to make them crisp, and tying them up in regular succession. Let covering-up for blanching *Celery* and *Endive* proceed frequently. Brown and Bath Cos Lettuce, as well as the Hardy Hammer-smith Cabbage Lettuce for early spring use, should now be pricked out, especially if becoming what is technically termed "proud." Cut away all superfluous shoots on *Tomatoes*, and if the plants are gross chop away a portion of their roots.

FRUIT GARDEN.

Look frequently over fruit remaining out of doors and gather it as it becomes fit, as if allowed to become over-ripe it will be liable to be blown down and bruised should high winds occur; also examine frequently that stored in the fruit room, as a few decaying fruit will occasionally be found for a few weeks after housing, and they should be removed as soon as they can be perceived. Keep the fruit room cool and airy, in order to allow of the escape of moisture given off by the fruit; the amount is considerable for a few weeks at first. Occasionally examine Plums or any other fruit protected by covering, to see that they are not spoiling. Where it is intended to make any fresh plantations of fruit trees this season the ground should be prepared at the earliest opportunity, and any fresh soil to be used for planting should be thoroughly exposed to the action of the weather so as to have it in a mellow state when wanted. If not already done clean and dress Strawberry plantations, clearing away all useless runners and giving a good dressing of manure where necessary, but be careful to select that which is thoroughly decayed, and which can be covered without the necessity of deep digging or injuring the roots.

FLOWER GARDEN.

The weather has lately been most favourable for the flower garden; the masses of colour are most brilliant, and, but for the falling of the leaves, we might deceive ourselves into the impression that summer is at its height, yet in a few more days we may anticipate a nipping frost which will lay prostrate the glories of our flower gardens. As there are many plants of which it will be desirable to preserve some of the old stock for flowering next year, it will be necessary that they should be potted in well-drained pots and placed in close pits till somewhat established. There are these advantages in preserving old plants, that they cover more space, and flower earlier and more abundantly than young ones. Finish all propagation. Let all plants be secured from frost and placed in their winter quarters, if not already done. Now is the time to plant out young hardy Conifers; they will establish themselves before winter. Finish pruning and regulating your shrubberies. I recommend an annual pruning and thinning as conducive to high order. The late Mr. Loudon was of opinion that every shrub in a garden should be a specimen of its kind, and coined for this style the term *gardenesque*, in contradistinction to the picturesque of

nature in wild scenery. When annuals have sown their seed on borders a great portion of the young plants may be carefully retained; they will bloom early and strongly in spring, especially the Californian kinds, and may, moreover, be transplanted in February to desirable situations. Lawns should now be well attended to as regards mowing and rolling; and Dahlias, *Helianthemums*, tall *Phloxes*, *Asters*, and *Delphiniums* should once more be examined and sticked before October. Take off all layers of *Carnations* and *Picotees*. Those which have but little root should be potted and placed under glass like pipings; this is better than allowing them to remain on the parent plant. *Auriculas* may be set in their winter quarters, only covering them during heavy rain. When the soil is dry about Dahlias draw it up round the stems to protect them from any unlooked-for frost.

GREENHOUSE AND CONSERVATORY.

Housing tender plants will at this period occupy attention. Where pits or frames are at liberty, or can be made so by rooting up the remains of exhausted Cucumbers, Melons, and other crops, there is no absolute necessity for stationing every plant or tribe precisely where it is to remain throughout the winter. Protection of this sort for a short time will contribute more than houses to the production of sturdy and well-ripened wood, possessing a greater tendency to blossom, and more capable of enduring a severe winter than would otherwise be the case. In such places they must be secured from the earth worms. This is easily accomplished, especially when the frames are raised above the common ground level. A good soaking of lime water should be followed by a coating of cinder ashes 3 inches in thickness. Nearly all house plants, except, of course, stove plants and Orchids, may be kept thus until the early part of November, taking care to mat-up at night in suspicious weather, and to give abundance of air in the day. The glasses or lights should by all means be washed thoroughly. Such a course as here detailed will prevent the hurrying-off of late annuals, *Achimenes*, and a variety of other gay things, in order to make way for the winter stock. Towards the middle of October, if not before, the *Chrysanthemums* ought to be staged, and housing them is frequently the cause of a rearrangement of a considerable portion of other stock. Those who have a house or pit for everything will not need any advice on this head; the majority, however, are very differently situated. Continue in the conservatory to weed out flowers of a temporary character on the eve of decay, and to supply their places with good specimens. The introduction, however, of some of the hardwooded tribes which have been placed out of doors (unless they can be placed in temporary situations for a while) will fill many vacancies. Every attention having been paid to autumnal and winter Roses, as recommended in former calendars, they will now be found of great utility, both in this and other ornamental structures. In cases where there are many stove plants in this house, it will be necessary, in the event of the weather becoming cold and wet, to use a little fire heat; but be as sparing of this as circumstances will allow, particularly if there are other plants in the house likely to be injured by being kept too warm. In the latter case it will be advisable to dispense with stove plants, even at the expense of rendering the house somewhat bare of flowers, rather than to keep them there and, on their account, run the risk of injuring other plants. Be careful not to overwater plants brought from the stove; also use water at a temperature of from 70° to 80°, as watering with cold water plants that have been brought from a warm house injures the young and tender roots, shortens the duration of the blossoms, and often ruins the plant. Use weak manure water for *Salvia splendens* and *geraniiflora*, so as to preserve the plants in a vigorous state, and keep them blooming as long as possible. Give air freely on fine days, and thin out the twiners on the roof wherever this can be done with propriety, in order to expose the plants to all the light possible. In housing the out-of-door plants, be sure to place the *Geraniums* and forward *Cinerarias* where they will enjoy both light and air, and near the glass if possible. Hardwooded plants may stand farther back, except young stock of *Eriacs*, *Epacris*, and similar choice subjects. The Chinese *Primroses* will do in partial shade, and in the dampest part of the house.

PITS AND FRAMES.

Continue to afford young stock careful attention, and endeavour to have it well rooted and strong, without keeping it so close or warm as to render it sappy and liable to damp off on the first approach of wintry weather, as is often the case with stock raised in heat late in autumn, and then stored in cold

pits for the winter. Admit air freely to all plants that are rooted sufficiently to bear it without flagging.—W. KEANE.

DOINGS OF THE LAST WEEK.

THE rains have done good to everything, but the frosty nights after the rain have rather interfered with the brightness of the flower garden, the petals of many of the *Geraniums* looking a little bleached, and the larger leaves of *Coleus* looking brown.

KITCHEN GARDEN.

We said so much on the kitchen garden last week, that we shall confine our remarks to two or three matters.

And first as to watering. We have three inquiries if it would be of any use to employ sewage water, not too strong, to Celery, Cabbages, and Brussels Sprouts after the rains we have had. If the rains have not been much heavier than we have had, we say decidedly Yes, as they have not gone deep enough with us; and, again, we would prefer giving a good soaking of such sewage water in damp, drizzling weather, as the plants would derive much more advantage from it than in fine sunny weather, when a portion of the watering would again be soon exhaled into the atmosphere. A cloudy, drizzling day is the best for giving an artificial watering a good chance. Sewage water though rather strong, will not injure such plants when roofing freely, and greatly helps to keep many intruders away. The smell at first deters many insects from laying their eggs, and all crawlers will keep aloof if they can find sweeter soil. A late bed of Brussels Sprouts planted in dry soil, and merely moistened well in the drill when growing and rooting freely, grew as if by magic after receiving a good watering at the roots with sewage on a drizzling day, with a smart shower at times. When the sewage is at all strong, or smells very much, it is well to keep it off the foliage, but when not very strong it will do no harm over the foliage of common things if it be clear enough to leave no deposit. When clear we have found it good to syringe with, for driving away green fly and red spider. We have found it as effectual for killing aphides on Cabbages, Cauliflowers, &c., as clear rather strong lime water. But when so used it should be clear, so as to leave no mark behind.

Our Cabbageworts are now getting tolerably clear of the fly, which threatened to clear everything before it. We noticed a fine field of Turnips the other day almost destroyed by the fly, whilst others have suffered greatly from grubs. It would have been true economy in the case of the first to have used a dozen or score of barrelsful of clear lime water, or clear, not too strong, sewage, and, in the second place, to have examined the ground round the Turnips, as the grubs keep near the surface in their first stages.

Brussels Sprouts Early.—Our earliest are just showing, but not so early as we would wish. We have several inquiries like that of "A Friend," who says, "I sowed early, pricked out, and then planted strong plants early, and what with sewage and other waterings they have grown strong and tall with fine broad heads, but the side shoots, the sprouts, are only showing, and seem as if they refused to swell." To gain the desired object, the fine tops must be stopped. The simplest mode would be to cut them off, but that would entail a loss, as these heads, after a little frost, are even sweeter, when cooked like young Cabbages, than the little sprouts. When a severe frost occurs immediately after the cutting, and the stem at all splits at the cut part, the stem is apt to be injured. To prevent any of these disadvantages, and yet encourage the firm side sprouts to swell, with a sharp knife take out from the crown the central axis of growth. You will hardly notice that the little central point has been withdrawn, but it will soon tell in throwing more strength into the side-shoot sprouts all up the stem. For winter and early spring use Brussels Sprouts and Scotch Kale will yield the greatest and most profitable gatherings, with, perhaps, the exception of a fine old quarter of Cabbage, each plant now forming a large stool. Young Cabbages just hearting are now exceedingly sweet and tender after the rains.

Endive.—A good portion of ours was pricked out thickly, so that we could water and shade it, as we could not have found water for it if planted at regular distances in the dry weather. A portion of this we have turned out with good balls, so as not to suffer from the moving, on raised ridges, one row along the centre and two rows on each side. We find that on such ridges the plants withstand frost and damp much better than when on the level, and when well established, with a little moisture at first they grow as freely and as strongly as if they were placed

on the level ground. The most forward may be tied to blanch them thoroughly; but for this purpose early in autumn nothing is better than placing a slate or tile over the plants, or even setting a pot firmly over them, and closing the hole securely in the reversed bottom. Endive looks well in the salad bowl, but for crispness and sweetness we never think it equal to Lettuce.

Cucumbers.—The beds made, as stated last spring, with rather fresh dung, with a layer of sweet dung and leaves over it, have yielded plentifully all the season, and with little more attention than air-giving, watering, and fumigation with tobacco paper twice or thrice. To make the plants fruit a little longer the front of the bed outside the frame was dug out, and fresh hot dung put in as a lining, the back of the frame being merely banked up to the top of the frame. The back may be turned over in a similar way afterwards if deemed necessary. A rough spout in front of the frame kept the rains which run down the glass from passing into and decomposing the bed.

The plants turned out for the first crop in a hot-water pit have succeeded equally well, and are doing so well now that we let them remain, though properly a part should be replenished. These have very little earth to grow in, and that we curtailed by planting them out in largish pots. No pots, however, have been seen for a long time, as the frequent slight rich top-dressings have concealed them from view. The pots are chiefly useful for securing early produce, and even afterwards they do something to secure fertility and prevent the growth of large parasol-like leaves—a matter of no importance, but rather to be desired in large span-roofed or even lean-to-roofed Cucumber houses, but to be avoided in small lean-to pits, where such vigorous growth would occupy more room than is desirable. We have grown some rather large kinds this season, but in general they are not profitable where the room is narrow. We were told, however, lately that a very long kind which our neighbour Mr. Cadger has in his Cucumber house, and from which fine crisp fruit upwards of 3 feet in length has been cut, does almost as well in an unheated pit in summer. Large Cucumbers, however, are turned from by many people just as they turn away from a large Melon. They will scarcely believe that the one is not old and that the other does not partake of the Gourd. Those who like Cucumbers will do well to eat them when crisp and young. We like them to be not more than from three-quarters to 1 inch in diameter.

We are glad to say that we have here seen nothing of the *Cucumber disease* for a number of years. Some Cucumber growers have it still, and cannot get rid of it. Very often a road or a field will make all the difference between having the disease and being without it. As we have frequently stated, we now repeat, that after more lengthened observation, we are still quite ignorant of the causes that brought the disease to us for years, and we are quite as ignorant as to the causes of its leaving us. After trying all kinds, and having seeds from all quarters—after using all kinds of compost, from fresh loam, fresh peat, or heath soil, and almost every conceivable mixture—it mattered not, the only relief we found was to be almost constantly sowing and constantly planting, for frequently the plants would only produce a few fruit before the disease assailed them. All washings of the house and pits even with boiling water, all washings of the plants, were quite ineffectual. It mattered not where we grew them—in places heated by hot water, in dung frames, in cold pits and frames without artificial heat, in ridges under hand-lights, in the open air without hand-lights, trained against fences or walls, and with plants from seeds sent from healthy plants hundreds of miles apart—the result was the same. No sooner did the seeming healthy plants begin to bear than the spot in the leaf, or gangrene of the fruit appeared; then all was over with them, nothing would restore them to health again.

During several years that the Cucumber suffered we never had Melons more healthy. Several who felt inclined to make a joke over our trouble have felt it was no joking matter when they themselves were involved, and felt their thorough helplessness to get out of the difficulty. We mention this more prominently, as we understand there are employers determined on having plenty of healthy Cucumbers, however frequently they should change their gardeners. They may succeed in so doing. There may be something like fortunate men in gardening. Singularly enough there are men whose handiwork hardly ever turns out successful. We have little faith, however, in a change of management getting rid of the Cucumber disease. All that we can do is to sympathise with those who are the sufferers. We feel quite unable to tell them how to

conquer and get rid of it. To us it is a greater mystery than the Potato disease, because it is so partial, and continuous for a time in its local manifestations. We have known cases of neighbours equally successful in growing Cucumbers, and whose practical routine was as much as possible alike, and yet the one without altering in the least his practice will have the disease for years, and his neighbour not have a trace of it; whilst when the first has got rid of the disease without knowing how, his neighbour afterwards will have to regret the presence of the malady. Perhaps when we know more of atomic vital organisms we may be in a way to find out the cause of the malady. At present our observations and experience point to the conclusion that the best Cucumber-growers in the kingdom may get the disease among their plants without knowing how, and be as powerless to free their plants of it as the young amateur who grows a bed of Cucumbers for the first time.

FRUIT GARDEN.

We have had several inquiries as regards gathering Pears. Just as in the case of Apples, early Pears should be gathered before they are quite ripe, and later kinds when the seeds are coloured, instead of being softish and whitish. We like all to be gathered before they are touched much by frost; but late kinds that keep well, if gathered too soon, will be apt to shrivel before becoming sweet and mellow, though juicy.

We shall here advert to two sets of inquiries, How are we to make the most of early Pears, and also secure their best flavour? The first was alluded to last week, such as gathering the most forward of the earliest kinds, and even giving them extra heat without the chance of losing or evaporating their juices. Fine flavour is often lost by laying early fruit on dirty shelves, on straw or hay not thoroughly sweet, or even on brown paper. As the fruit ripens it absorbs a scent or aroma from the surroundings. Few plans are more simple than placing clean packing paper or foolscap on clean well-seasoned boards from which all scent of the wood has gone. On that paper place the fruit singly, and cover it with paper to prevent the evaporation of the juices, and along with them a portion of the aroma of the fruit. Open shelves or platforms answer very well, but such things as shallow boxes or drawers do better treated as above; the latter with just a slip of an opening to let any moist air out. We have known the finest fruit greatly injured by being laid on straw or hay not thoroughly dry, and not perfectly sweet, or liable to become damp from the moisture exhaled from the fruit. Late fruit may be treated less ceremoniously by being placed carefully in greater heaps instead of being laid singly, though the latter mode would be the better where room could be given; but as the most forward of these approach maturity they will be improved by being placed singly some time before using, and in many cases will be improved by being kept a little warmer, but not so much so as to sacrifice juiciness and flavour to mellowness.

The second inquiry has reference chiefly to a fertile source of disappointment at *country shows*. "JUNIAS" asks our help to unravel the mystery. He says, "I showed splendid large round Potatoes, but was beaten by kidneys of half the size; large Cabbages, but was beaten by smaller ones. I showed large Pears of Williams's Bon Chrétien rather ripe, Louise Bonne, and Beurré Bosc, and was beaten with small Bergamote not bigger than eggs; and in the same way my Cellini and fine Alexander Apples were beaten by small Kerry Pippins, and huge fruit of Victoria and Washington Plums were walked over by Green Gages anything but remarkable." The suitable reply is that most judges without specific directions award according to quality rather than bulk and quantity. We saw a man very wroth because huge round Potatoes with eyes nearly an inch deep, and therefore involving great loss if judged necessary to pare them, passed over, and the preference given to fine Mona Kidneys scarcely showing in their outline where an eye was placed. The remedy in such cases is to show in classes, such as round and kidney, white, and red, and other colours. The second remedy as to fruit is also to show in classes, such as for dessert, cooking, and even weight. For dessert nothing will beat Green Gage Plums if good, except fruit equally well ripened of Coe's Golden Drop. Fine specimens of such a dark rich Plum as Kirke's would run hard a dish of Green Gages if fault could be found with them. For table the Victoria and Washington would have no chance with them. Again, as to Pears, few kinds take so many prizes in autumn as the Bon Chrétien, but we have often seen it, when over-mellow and mealy, beaten by small fruit of the rich Bergamot just when in its prime, and both beaten by the Louise Bonne of Jersey when at its best.

The Cellini and Alexander Apples have no chance with the Kerry Pippin for the table, just as the little rich Apple would have no chance with them for the kitchen, and neither of them would have any chance with other Apples when size and weight were to be the criterions. Making classes is the only way out of the difficulty. Without it neither judges nor exhibitors will be satisfied. For instance, if amateurs were competing in Plums, we would give the preference to good Green Gages. Were cottagers competing we would have a hankering to give a preference to large Victorias or Washingtons. In this case, too, we should look on a huge Cabbage, firm and without cracks, in a different light from what we should look on a Cabbage destined for a gentleman's table. Size and weight should by no means be overlooked in the productions of cottage gardens, as what will fill the pot is of primary importance.

The wind of the 11th shook many fruit from all high orchard trees in this district, but it did comparatively little harm in the case of our bush and low pyramidal trees. When much planting of fruit trees is contemplated, and time and space are at liberty, it would be well to prepare for planting by trenching, station-making, &c. We have in unpropitious circumstances great faith in station-making, planting shallow, and yearly mulching, as securing fertility without much or any root-pruning. The sooner now that all weakly second growth is removed from fruit trees, the more will the sun and air have a chance to perfect the buds.

ORNAMENTAL DEPARTMENT.

The lawns are now lovely, perhaps all the more so when contrasted with the previous brownness; and notwithstanding the rains and the next to hurricanes of wind the flowers are still passable, though far from being what they were a fortnight ago.

We shall conclude our gossipings this week by alluding to two kinds of flowers which we can recommend as most useful to all those who from choice or necessity are obliged to supply a great quantity of cut flowers. Our own opinion is that cutting nice flowers to be put in vessels of all sizes and shapes, in all parts of rooms, to be thrown out in a couple of days, is not only carried a great deal too far, but that it is acting, and will continue yet more to act, most prejudicially on the health of the residents. Even a good and cheerful effect from moderation may easily be carried too far. But on this we shall not dwell at present, but where such flowers must be had in abundance, we would recommend the varieties of *Phlox Drummondii* and *Salpiglossis*. We think we had about a dozen varieties of each. We sowed them under glass in the middle of March, pricked the plants out in a bed under a little protection, then lifted them with little balls at the end of May, and planted them out. On an average the flowers of these will stand in damp sand four times as long as scarlet Geraniums.—R. F.

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

Books (*E. S. S.*).—"The Fern Manual." It is published at our office, price 5s., free by post 5s. 4d. (*H. F.*).—"Fruit-Growing for the Many," can be had free by post from our office if you enclose five postage stamps with your address. It contains directions for Melon culture. (*J. B.*).—There is a volume called "The Language of Flowers." You could obtain it through any bookseller.

Kew Gardens (*C. J. P.*).—No preliminary examination is required of a young gardener before he can be employed in the gardens. If you write to Mr. Smith, the Curator, he will give you any information you need.

Dwarf Ageratum (*E. H.*).—We do not know the variety. Send a specimen to Mr. Chater, enclosing a stamped directed envelope, and ask him if it be true to name.

Phlox Drummondii Culture (*E. T. H.*).—The cause of your Phlox Drummondii not flowering well is its being under a south wall, where it would be parched with heat and drought. Had you given it an open situation and rich light soil, it would have bloomed well, if watered in dry weather. It is merely necessary to sow the seed in a hotbed in March, prick off the young plants when large enough to handle, placing them about an inch apart, and to plant them out at the end of May in rich light soil in an open situation. Phlox Drummondii Heyuheldi, scarlet; Kadowitz, striped; Oenata alba, white and crimson; are three good varieties, but all are very good. Mr. Chapman's cases may be seen at some of the principal London seedsmen's shops.

Hardiness of Echeverias and Sempervivum Californicum (*Nemo*).—The first two require to be taken up, potted, and wintered on a dry shelf in the greenhouse. They will need but little water. Sempervivum californicum is quite hardy, except when it has been grown in very rich soil, and then, from being very succulent, it is liable to be injured by frost. To winter it well, the soil should be light and properly drained. Take up a few plants, or all, and winter them on a dry shelf along with the Echeverias.

Spina Pear.—"Z." wishes to know the name of the Pear met with from the 1st of January to the end of March all along the south of France and in Italy. He was told, doubtfully, it is called "Spina."

CHRYSANTHEMUM LOUISE HONORARY (*Centurion*).—Your seedling plants about 5 inches high we would prick out now in a sheltered situation at about 6 inches apart, and leave them for the winter, cutting off the tops in spring. Early in summer place the plants in small pots, and shift into larger as required, giving the final shift by July. It is a hardy perennial Pompon variety. We do not think your plants will flower this autumn.

MISS INGRAM ROSE (*Idem*).—It is in every sense a Hybrid Perpetual, as much so as any other, but like some others of that class, is not a free autumn-flowering kind, though a beautiful Rose. Of the two Strawberries you name, there is none better than Dr. Hogg for a light sandy soil, but it needs good top-dressings and copious waterings.

PRUNING ROSE BOULE DE NANTERRE (*William Tyrer*).—We have no difficulty in getting this Rose to flower, and we cut in the strong shoots to six, the moderately strong to three, the rest to two eyes, except the very weak shoots, which we cut clean out. We do not know of any mode of keeping Tomatoes after they are ripe.

MILDEW ON ROSES (*Q. Q.*).—When mildew occurs on a few plants, try vinegar and a sponge. I cured my pot plants with it. It entirely removed it. When mildew occurs over the whole of a large rose, the cure becomes hopeless. Try in this case 2ozs. of blue vitriol dissolved in hot water, and added to three gallons of cold water; pour this with a rose over the leaves. Sulphur blackens the foliage, and stops up the pores or stomata of the leaves, causing for a time the same mischief as the mildew. Your attack is owing not to the mill dam, but to the situation and aspect, which, in such weather as we have had, are favourable to mildew. I have a little here. I cut off occasionally a twig, and destroy it, but when it occurs simultaneously over a large rose, it is a hopeless case. You must carefully wash out your watering-pot after using the vitriol.—W. F. RADCLIFFE.

ROSES IN POTS WEAKLY (*Thomas*).—Your very small Roses in very large pots we would at once shake out and repot in a compost of two-thirds fibrous loam, and one-third old cow dung or well-decomposed manure, with a free admixture of sharp sand, draining the pots well, and using a pot large enough to hold the roots, but not a large pot. Water the plants and place them on coal ashes in the cold frame. Admit air in mild weather, protect from heavy rains, and cover the lights with mats in very severe weather. Prune the plants rather closely when the buds begin to swell.

SEASON OF ENDIVE, RHUBARB, RADISHES, AND LETTUCE (*Idem*).—Endive is in season from September to April, and may be had from August; Rhubarb from November to July; Radishes from March to November; and Lettuce from March to November. You will need means for forcing the Rhubarb so as to have it in winter, and for blanching and keeping the Endive from frost, but for particulars consult "Kitchen-Gardening for the Many," price 4d., or free by post for five stamps.

GATHERING GRAPES (*An Amateur*).—As you do not require the Grapes after Christmas, you may leave them on the Vine. If your house is dry they will keep very well; but if it is filled with plants they will cause dampness, which will endanger the keeping of the Grapes. In the latter case we would advise you to cut the Grapes when they are fully ripe, retaining along with each bunch a portion of branch—say from 4 to 6 inches long; insert it in a narrow-necked bottle filled with water, and enough powdered charcoal to cover the bottom about half an inch deep. The bottle should incline to one side, so that no part of the bunch may be pressed against the bottle. The Grapes may be kept in any cool, dry room, where they should be looked over occasionally in order to take out any decayed berries, and to replenish the water when from evaporation it falls to a level with the end of the branch. By this means you can cut the fruit, and employ the house for plants, pruning the Vines at the proper season.—G. A.

CAMELLIA BUDS THINNING (*Idem*).—The shoots terminating with three or four buds should have the latter thinned to two each, and if the plants are weak one bud to each shoot is sufficient. The earlier this is done the better.

FORCING LILY OF THE VALLEY (*Centurion*).—The plants should be taken up and potted, selecting those with round plump crowns. If small and long, with sharp points, they will give little beyond leaves. You may take them up from now to March as required. They will flower at Christmas if potted at the end of October and introduced into a house with a temperature of from 40° to 45° for three weeks, and then increased or moved to another with a temperature of from 45° to 50°. Six-inch pots answer very well, but we use pans a foot across, and put in as many roots as we can. If they are an inch apart they are not too close. Over the pots, when placed in the house, invert another pot of equal size, and keep it there until the flower-stem is 3 inches long, then remove it. Any kind of light rich soil will answer very well.

APPLES (*Idem*).—The Apples you name are in season during the months of November, December, and January. Reine des Royales is distinct from Reine des Canadas. You would find complete answers to such queries in the "Fruit Manual."

GROWING ZONAL GERANIUMS IN LARGE POTS (*M. A. M.*).—You will, of course, take them in doors before frost, and in winter give them only water enough to keep the leaves from flagging, and if the old leaves fall off no matter. In March, or when the plants begin to grow, cut them in, leaving enough wood for furnishing fresh shoots, and do not water much until they have begun to grow. When they have shoots an inch or two long repot the plants, removing most of the old soil. If you can get them into a size of pot smaller than that in which they were grown do so. Keep them moist, but do not water very much until the roots are spreading freely in the fresh soil, as you will know by the growth of the plants, then water them more freely. In May transfer them to their full-sized pot. It will be necessary to tie down, stop, and otherwise regulate the shoots so as to form compact plants. A compost of equal parts of turfy loam and old hotbed manure, or leaf soil, with a free admixture of sharp sand, will grow them well. Good drainage is necessary. If your plants are bare of shoots near the base, young plants would be better, but they will not flower so finely nor be so large as the older plants. Try them again.

FRUIT TREES, STRAWBERRIES, AND ROSES FOR A GARDEN NEAR THE SEA (*M. G.*).—In a position not far from the sea, and fully exposed, we have succeeded on walls—Pears: Albertaine, Marie Louise, Beurre d'Etel, Beurre de Rance, Passe Colmar, Van Mons Leon le Clero, Knight's Monarch, Flemish Beauty, Glou Morcean, Bergamotte d'Espereon, British

Queen, Winter Nellis. *Plums*: Green Gage, Kirke's, Jefferson, Coe's Golden Drop; and for kitchen, Pond's Seedling, Victoria, and Prince of Wales; if a white Plum is wanted, White Magnum Bonum. *Cherries*: May Duke, Black Tartarian, Bigarreau Napoleon, and Late Duke *Apples*: Adams' Pearmain, Red Lustre, Golden Pippin, Cellini, Cox's Orange Pippin, King of the Pippins, Scarlet Nonpareil, Sykehouse Russet, and Kerry Pippin. *Strawberries*: Black Prince, Sir Joseph Paxton, Keens' Seedling, Dr. Hogg, Sir Charles Napier, Frogmore Late Pine, and Mr. Radclyffe. *Standard Roses*: Alfred Colomb, Anna de Diesbach, Baronne Prevost, Caroline de Sansal, Charles Lefebvre, Comte de Nanteuil, Duc de Rohan, Engoule Verdier, Jean Bart, John Hopper, Jules Margottin, King's Acre, Lord Clyde, Louise Peyronny, Madame Charles Wood, Marchal Vaillant, Prince Leon, Senateur Vaisse, Victor Verdier, Souvenir de Leveson Gower, and William Griffiths, all Hybrid Perpetuals. For walls: Gloire de Dijon, Climbing Devonians, Marchal Niel, Tea-scented; and of Noisettes: Jaume Desprez, Lamarque, Solfaterre, and Cloth of Gold. These require walls with aspects between south-east and south-west. For other walls and trellises: Alice Gray, Danco Rambler, both Ayrshire Roses; Myrtilles, Rimpant (Evergreen); Madame d'Arblay, and Rivers's Queen (Hybrid Climbing). In your light soil it will be necessary to manure well.

WINTERING PLANTS IN A COLD VINERY (Merlin).—To winter bedding plants safely you ought to have a stove or other means of keeping out frost. Though you will need artificial heat, it need not be so great as to cause the Vines to start into growth. A temperature of 40 from fire heat will not injure the Vines, and will insure the safety of every kind of bedding plant. Could you not have the house heated by hot-water pipes? A small saddle-boiler with a stove-hole outside would be better than a stove inside the house. There is no possibility of keeping bedding plants in a vinery unless frost can be excluded. Heat is requisite in dull damp weather for expelling damp, and would be useful for the Vines in a cold wet season. The Vines may be pruned at the beginning of December, or when the leaves have fallen. Pruning ought not to be deferred beyond the middle of December. The Vine border would be better if covered, but many borders are not covered, yet good Grapes are produced. It would be well to find another place for the annuals and to cover the border, but, instead of tarpaulin, for a cool vinery a top-dressing of rich compost and half-inch bones may be employed; but the annuals will keep the sun and air from the border, besides depriving the Vines of support.

FRUIT TREES NOT BEARING (Idem).—You will best restore your trees to fertility by taking them up this autumn as soon as the leaves fall, lifting each carefully and with a good ball, and replanting at once. The standards, which we presume are orchard trees, we would not lift, but merely thin out the shoots if too numerous, or, if not sufficient to form a good head, shorten the long vigorous shoots half their length. Why give the trees liquid manure when their growth is rank? With lifting in autumn you ought to check the vigour of the trees, and so induce fruitfulness. As regards the wall trees, we would take out the trench about 2 feet from the stem, cut off all roots there, and any roots that strike perpendicularly downwards between the trench and the stem, working under the roots. Then fill up the trench and mulch the ground, also that round the bushes, with 2 or 3 inches thick of short littery manure. Keep all shoots well pinched in in summer, except those required for extension. The Apple trees are infested with American blight. Syringe the trees well with a solution of 2 ozs. of soft soap to a gallon of water, directing it against the parts infested with the insects. You may obtain self-registering thermometers of most nurserymen, or of any optician. The cause of plants of Geraniums and Fuchsias losing their leaves when taken into rooms is the want of sunlight; by retaining their freshness longer when taken from the open ground may be a result of their greater hardiness.

VINE PLANTING (Reader).—We see no objection whatever to your planting your Vines in the autumn instead of the spring or summer, and just because the ground would be warmer we would prefer planting in September rather than in October. As they are to be planted inside protection is less necessary, but even then the longer the soil is kept warm the more will roots be made after planting. If the roots were out of doors we would cover with litter deep enough to keep out frost, cold rain, and snow. We have planted Vines that grow freely in June and July. In these summer months, if there is much spreading-out of roots, there is apt to be a check if not guarded against.

BLACK MUSCAT GRAPES (W. M.).—Our experience of Mrs. Pince's Black Muscat Grape is very much in accordance with your own, and we regret to say it is almost universally so. The bunches, as you observe, do not set regularly, neither do they colour very freely. Both the bunches and the berries are large, and the latter of excellent quality; it is of considerable merit as a late-keeping variety. It is one, however, which, in our opinion, has been far too much lauded, and altogether unworthy of extended cultivation. In marked distinction to this we have Madresfield Court Black Muscat, which is in all respects excellent, and we have seen it in many places this season. It is possessed of all the qualifications of a good late Muscat black Grape, splendid constitution, free fruiting, large bunches and large berries, fine jet black colour, and good Muscat flavour—truly a meet black companion for the white Muscat of Alexandria. We strongly recommend this Grape. Muscat Champion is a very fine, large grizzly Grape, with a Muscat flavour. When well grown and ripened it is excellent, but, like the Canon Hall Muscat, it is somewhat difficult to secure it in this condition.—A.

VINES (W. G. C.).—Mrs. Pince's Black Muscat is not suited for a cool vinery. Muscat Hamburg grafted on the Black Hamburg succeeds only moderately well in a cool house. All Grapes having the Muscat flavour require best to bring forth the mnsky tastefully. The Frontignan class (the Petites Muscats of the French), require the least. Mrs. Pince is a good-keeping late Grape, but we much prefer the Madresfield Court Black Muscat. Your selection of Peaches is very good. For the Nectarines, however, we should prefer Elruge and Balgovan as two of the best and most constant varieties grown. The fruit on Black Hamburg Vines as they are commonly met with varies considerably according to cultivation. The variety called Frankenthal has large roundish oval berries, hammered, the bunch well shouldered and compact. The true Black Hamburg has smaller berries, more oval, smooth, with a more loose and straggling bunch. We should say you distinguish them properly. The third variety is the Dutch; berries very large, round, and hammered, very coarse in quality, but beautiful in appearance. We should say this is the one you have. The Champion or Millhill has very large, round,

smooth berries, which scarcely ever become quite black, and have a very tender skin and fine flavour. It is of delicate constitution.

SELECT APPLES AND PEARS (A Poor Lady).—The following may suit you. *Autumn Apples*.—Cox's Orange Pippin, Kerry Pippin, and 1 Summer Whorle. *Pears*.—Williams's Bon Chretien, Beurre d'Amanlis, and Jersey Gratiosi. *Apples for April and May*.—Scarlet Nonpareil, Golden Reinette, Braddick's Nonpareil. *Pears*.—Ne Jplais Meuris, Zephirin Gregoire, Josephine de Malines.

HARDINESS OF CINERARIA MARITIMA (B. G.).—It is quite hardy on all but very heavy wet soils, and in very exposed situations. We find it does best when the old tops are left, as they to some extent protect the crowns from the severity of the winter, and to make all safe we generally mulch round the plants with partially decayed leaf soil. The tops are cut off in winter by the frost, so that the plant is not one to be recommended for spring gardening, or not until late. It is best in summer. The dead tops should be cut off in spring.

ECHEVERIA SECUNDA GLAUCA (Idem).—It is not hardy, nor will any of the Echeverias stand the winter. Sedum, or Scimpervivum californicum, however, is quite hardy in dry soils and favourable situations. It is a fine plant for edgings.

NAMING APPLES AND PEARS (Idem).—If you send them to us carriage paid, and each kind numbered, we will endeavour to name them for you. Half a dozen will be enough to send.

HOYA CARNOSA FRUITING (Charles Walters).—It is rather unusual for this plant to have pods, but there have been several instances this year of its fruiting; indeed, such are becoming general. The cause of its doing so is, undoubtedly, the bright weather we have had.

ASPARAGUS MANAGEMENT (Glaucous).—Your three-year-old plants planted last autumn could not be expected to give you any heads fit for cutting last spring, and we think they will not do much for you next year, though you may cut all the heads that are of a size fit for cutting, and let the small grow; but we would advise you to be satisfied with a little next season; the produce will be quite yellow, and cut it off early in November. Clear the bed of weeds, give a top-dressing of manure 2 or 3 inches thick, and cover about half as much with soil from the alleys. If the manure be only partially decayed it will do. In March remove the loose portion of the manure, or point the beds over with a fork, not going so deep as to interfere with the crowns, and rake the beds, drawing the rough soil into the alleys. At the end of March sprinkle the beds with salt, and again in May, in the same way as you would for destroying weeds on walks; and from July to the middle of September you cannot water too freely nor too often with liquid manure. In the following spring you ought to have a plentiful supply of heads.

TOUS-LES-MOIS (Indicus).—We cannot tell you where you can obtain the seeds of the plant from whence this flour is obtained, but probably through some West India merchant. Dr. Herz, in his "Vegetable Kingdom," says, "The article known as Tous-les-mois is obtained from the root-tubers of some species of Canina, by some supposed to be *C. coccinea*, and by others *C. acurata*. The substance is prepared in the island of St. Kitts, and it is said that its manufacture is attended with a great deal of difficulty; it is highly nutritious, and is an excellent food for infants."

CATEPILLARS ON GERANIUM AND STACHYS LANATA LEAVES (E. M. T.).—There is no better plan than to boil fresh Elder leaves in as much water as will just cover them until it is quite black, then strain, and water the plants overhead when quite dry through a fine-rosed watering-pot, giving a good wetting. Dusting with white hellebore powder will serve the same purpose. Handpicking is an excellent remedy.

VARIEGATED GERANIUM LEAVES (Kittie).—We do not undertake to name florists' flowers, and it is extremely difficult to identify the variegated varieties by their leaves; but we think yours are—1, Silver Nosegay; 2, Flower of Spring; and 3, Flower of the Day.

PYRUS JAPONICA (S. T. H.).—We do not know of any economical use to which the harsh and gritty fruit of this Quince can be put.

FLOWER GARDEN ARRANGEMENT (Rush).—We like the arrangement very much, and are pleased you have the boldness to make the four beds round the centre similar, as we believe attempting more variety would not be so effective. As you ask particularly about 5 and 6, we should be inclined to reverse them, as the four 2 beds have Golden Chain round them; we would therefore plant 5, 5, with Madame Rudersdorf, and edge with *Oxalis corniculata rubra*; then we would edge 6, 6, with *Cerastium*, and fill with Mrs. Pollock, dotted all over with *Lobelia*.

SEEDLING PLUM (W. Miles).—Your seedling Plum, although good, is so similar to others already in cultivation, that we can see little use in introducing it. It is inferior to the variety called Poupert's, which it somewhat resembles.

BERGAMOTTE D'ESPEREN PEARS (Lang).—Let them hang on the trees as long as they will, say till the middle of next month. When they come off freely is the time to gather.

ROSE BUDS (Idem).—It is somewhat late now for budding; you may, however, try. They might do on the Manetti stock.

SIFTED LIME RUBBISH FOR A LAWN (H. S. W.).—For a lawn liable to get scorched in summer lime rubbish would be the worst possible application. We should give a top-dressing of rotten manure next March, rake the lawn well in April, and sow over it Trifolium minus at the rate of 12 lbs. per acre. It is not so liable to brown as grass is in summer, besides it is always of a bright deep green. Its drawback is its numerous small white heads of bloom, but run over with the mowing machine once a week all is kept neat.

APPLYING LIQUID MANURE (A Constant Reader).—Manure water to be of any benefit should be given when the plants are growing, or during summer. It may be given from the commencement of growth up to its completion, but will not be needed in wet weather.

PLACING FLINTS AROUND THE STEMS OF SHRUBS (Idem).—The practice was recommended by London partly to keep the ground near the stem from being disturbed, and to prevent weeds growing, and to afford warmth; but as the flints can do no good in any of those ways in protected or enclosed grounds, we think it a needless proceeding.

EAST LOTHIAN STOCKS AFTER FLOWERING (Q. Q.).—The plants will not be of use for next year's flowering, but if you wish for seed you may pot them, and winter them in a cold frame. That is the only purpose for

which they are fit. They will not live out of doors except in a warm dry soil and situation.

ASPARAGUS PLANTING (*Idem*).—You may in October plant in the permanent bed, and after planting cover with the top-dressing of manure as for established plants. It would be better if you could defer the planting until spring.

SOWING GRASS SEEDS (*N. C. H.*).—The seeds sown last week will not suffer from frost, and as far as the covering with stable litter as soon as the grass shows, it would do more harm than good; but were it put on thickly before very severe weather sets in it would prevent the soil lifting, and so be a great protection to the Grasses and Clover.

SOWING TRIFOLIUM INCARNATUM AND ITALIAN RYE GRASS (*Idem*).—We have known them succeed well from sowing in the first week in October, but the season was mild. That we consider is as late as they should be sown, and we would if possible sow in September. The earlier the better for early spring cutting.

DRYING FLOWERS (*W. Y.*).—Everlasting flowers should be gathered as soon as fully expanded, and dried by hanging up in a dry warm place. To dry other flowers take some fine white sand (that called silver sand is the best), wash it repeatedly until all dirt is removed, and the water remains clear. Next dry it thoroughly, and half fill a vase, a stone flower pot or a glass with the sand; in this stick fresh-gathered flowers in their natural position, and afterwards cover them gently with the sand, taking care not to damage the petals. Now place the vessel in the sun, or in a room where a constant fire is kept, and let it remain until the flowers are perfectly dry. Then remove the sand carefully, and clean the leaves with a feather brush. You must gather your flowers for this purpose when they are dry—that is, after the dew has evaporated. The process succeeds best with single flowers, but the difficulty attending such double ones as Pinks, Carnations, &c., may be avoided by splitting the cup on each side, and when the flower is quite dry the incision made to adhere by means of gum water; or the cup may be pricked around with a pin to let out the moisture. White flowers lose their natural colour by this process, but it may be restored by exposing them to a moderate vapour of brimstone; but crimson or scarlet flowers should be placed in a vapour of the solution of tin in spirits of nitre. The green leaves and stems are renovated by the vapour produced from a solution of steel filings in oil of vitriol. When dried the scent of each particular flower may be artificially renewed by dropping into the middle of it some of its essential oil: thus oil of Cloves will scent the Pink, oil of Roses the Rose, oil of Jasmine the Jasmine, &c.

REPORTING FINE PLANTS FOR NEXT SCHIMMER'S FRUITING (*W. S. S.*).—We should have potted the plants in August into their fruiting pots, and placed them low, so as to allow for top-dressing; but that not having been done, delay potting until February, and then shift into the fruiting pots, not discarding the plants, nor removing more of the old soil than will come away freely. Encourage growth with a brisk bottom heat and moist atmosphere, but do not water very freely until growth is vigorous.

SCARLET RHIBARBE (*W. C.*).—All properties considered, there is no finer scarlet or red Rhubarb than Tobolsk, or small Old Red. It may not suit the cook, but it does the table. An improved form of it is Baldry's Scarlet Deference. It is larger, and possesses all the other good qualities. Salt's Crimson Perfection, which you have, is also good.

CHRISTMAS ROSE (*Nuss*).—This (properly *Helleborus niger*) is quite hardy, and succeeds in any soil, but best in one which is well drained, light, and enriched with vegetable soil, such as leaf mould. It is propagated by dividing the roots or plants into as many parts as you can make with roots and crowns to each. This is best done in spring, though we have divided the plants very successfully at this time of year. It is desirable to give the plants a position shaded from the direct midday sun in summer; hence an east is preferable to a south border.

RED-FLESHED MELON (*Idem*).—Malvern Hill is a fine scarlet-fleshed Melon of delicious flavour.

APPLYING GAS LIME, SALT, AND SOOT (*W. L.*).—Gas lime is so powerful that it should not be applied to garden ground except in small quantities, and to that not required for cropping for some time afterwards. It should be spread evenly on vacant ground in November or February, and be dug in; indeed, in gaudous as a manure it is best not to use it, though for making the ground obnoxious to insects feeding on the roots of plants it has been found useful. Twelve bushels per acre are ample to effect that, and all we advise. Salt is beneficial as a manure. It should be sown broadcast over the ground in spring. Twelve bushels per acre are sufficient. Soot is a good manure sown broadcast in spring during moist weather. Sixteen bushels per acre are enough. It may be used along with salt, and at the rate of ten bushels to six bushels of salt. This mixture is found excellent as a manure for Potatoes, and would probably suit most vegetable crops.

EXTIRPATING HORSEWEED, BINDWEED, AND CATCH GRASS (*Idem*).—For destroying Hor-etal there is no remedy but draining. Drain the ground and it will disappear. The Bindweed is only to be destroyed by forking or digging the ground over deeply, and picking out the roots, which, though a tedious, is a sure process. In summer keep the tops pulled up as fast as they appear, which will prevent the roots increasing much. Couch should be forked out; indeed, in gardens there ought to be none. Whenever a blade appears fork out the roots.

CHARRING REFUSE (*N. A.*).—No letters have been received from you before. The article you refer to is in No. 474. If you enclose four postage stamps with your address it will be sent to you by post. It is too long and too recent to reprint. It is impossible to name Strawberries from the characteristics you give, they vary so much with soil and season. If you send specimens of the fruits we can aid you.

ZINC EXPOSED TO FIRE (*H.*).—We do not think a tank made of zinc would long resist fire heat under it. Gas heat would not so soon affect it if the flame were not very near the zinc, but the alternate expansion and contraction from heating and cooling soon destroy a zinc vessel. A small gas stove, or an argand jet in a confined place with a slit to admit air, would be quite sufficient for such a small tank. If you wanted the tank for propagating, and thus getting bottom heat, 3 inches deep would be better than 5 inches.

FLECK-HEATING (*East Leamington*).—For such a flue as you describe you want no damper; regulate draught by the ash-pit door. To succeed, see that the furnace-bars are from 18 to 24 inches lower than the bottom

of the flue. If your inside border is well made, and is 13 feet in width, there is no reason why the Vines should not flourish planted inside if they were timeously watered and surface-manured. It is awkward having the house so situated that snow resting on a slate roof, when it slips, would slide down on the glass roof, for if at all heavy it would go through the glass. A barrier about 13 or 18 inches in height between the slates and the glass would prevent or lessen the evil. In a similar case where a barrier would be unsuitable, we have used wooden shutters, or even shutters or covers of sparred wood to lay over the lights where the snow was apt to fall, and thus saved the glass. It is seldom that would be wanted except in heavy snowstorms.

HEATING BY GAS (*P. S.*).—If you buy No. 311, where drawings are given of gas stoves, you can select which you please. You can have it by post if you enclose four postage stamps with your address. We do not know how you manage your stoves. Could you increase the number of burners? and then, the piping being increased, you would get more heat. Argand burners give a great deal more heat with less consumption of gas than common jets. We presume your gas goes through the 1-inch piping. We would be glad to assist you if we knew how.

VANTORS (*J. quintin*).—You will not have any extra heat in a span-roofed house 14 feet wide that has only two flows and one return-pipe. However, if it does for Strawberries from the 1st of January to the 1st of July, it would do admirably for Melons from the 1st of July up to the end of October, and for Cucumbers until towards the end of November. The uses to which such a house may be put during the six months are endless, but as we do not know what you chiefly want, it would be idle to particularise them; but we may mention growing tender annuals, Capsicums, Chilies, &c. You plan of getting Strawberries at Christmas has often been tried, often succeeded, and oftener failed. We have gathered good dishes on Christmas-day, and we have hardly had any when we tried for them. Success greatly depends on the end of November and part of December being bright and sunny. It would never pay to force so early generally. By your proposed treatment the plants would be matured and rested early, but even in such cases our success has not been uniform.

NAMES OF FRUITS (*Constant Reader*).—Your Pear was quite rotten. (*A. Noyce*).—Pears: 1, Nonvent Poiteau; 2, Passe Colmar; 3, Beurré Diel; 4, Grou Morceau; 5, Beurre de Rance; 8, Beurre Diel; 12, Susette de Bayay. (*H. M.*).—Plum: Smashed all but a small portion of one end, which had the appearance of Prince of Wales. (*H. L.*).—We have some difficulty in determining your sorts: 1, Not known; 2, English King's Pearmain; 3, Pine-Apple Russet, probably; 4 and 5 are the same—we think Munchie's Pippin, certainly not Irish Peach. (*P. M.*).—Plums: 1, Belle de Septembre; 2, Diamond; 3, Gisborne's, very fairly grown. (*W. Miller*).—Apples: Your specimens are so very small and scrubby, many of them no larger than small Crabs, possessing no characteristic features, that it is quite impossible to name them. We think 21, 34, and 35 may be Hawthornden; 14 and 30, Court of Wick; 15, Cole; 32, Golden Harvey, or Harvey Russet; 24, Sam Young; 1, Baxter's Pearmain; 8 and 9, Scarlet Nonpareil. (*Walsam Court*).—Your Peach—1 A, looks like Bellegarde, but we cannot tell without knowing the character of the flowers and leaves. Nectarine 4 D, is Elruga; 5 F, Red Roman, a clingstone, which is rather apt to fall in a semi-ripe state. Fig 3 C, is Brunswick; 2 B, Brown Turkey. (*W. Kerr, Dumfries*).—Your Apple is, we believe, Bateborodova.

NAMES OF PLANTS (*W. T.*).—We cannot name plants from their leaves only.

POULTRY, BEE, AND PIGEON CHRONICLE.

PRIZE CUPS FOR BRAHMA POOTRAS AND COCHIN-CHINAS AT THE PLYMOUTH SHOW.

In following the very spirited example of several gentlemen connected with other shows, I hope I may be at least as successful in obtaining subscriptions sufficient to provide two silver cups for the best Brahmas and Cochins at the forthcoming Plymouth and West of England Poultry Show. The admirers and breeders of the above varieties are apparently scarce in the more western counties of Devon and Cornwall, and it is hoped that the inducement thus held out will not only bring together a collection of specimens superior to those hitherto exhibited at Plymouth, but contribute in some degree to the greater and more successful cultivation of the Asiatic breeds, which are at once the finest and hardiest birds in the poultry-yard. I may add that the two cups usually added by the Committee will still be offered for the best specimens in the Show, irrespective of the subscription cups. Any gentleman intending to subscribe will greatly oblige by communicating his intention to me as early as convenient.—JAMES LONG, 23, Princess Square, Plymouth.

ANTWERP PIGEONS.

WITHOUT wishing to disparage the claims of any of the beautiful varieties of the domestic Pigeon now cultivated, I would say to those about to enter upon the Pigeon fancy, who are undecided what particular kind to keep, Try the Antwerp. It is as hardy as any, more prolific than most, and for beauty of plumage and sprightliness of carriage will bear comparison with any other variety, in addition to which it is more sensible than any other breed, and when once settled to a particular locality is not readily lost.

There is no necessity for building an expensive house with a southern aspect for its reception, any spare corner in an out-house will do—east, west, north, or south, it is quite immaterial. Having selected a convenient place, build a pen about 5 feet high, 10 feet long, and 3 feet deep; at each end fix shelves a foot deep and about a foot apart, placing a division in the centre of each, which will give two nesting places on every shelf. These should be supplied with loose boxes about 9 inches square and 3 inches deep. In the blank spaces between the rows of shelves, and at the back of the pen, fit up about a dozen rests for the birds to perch upon, of any description, according to fancy. The old-fashioned triangular shape is as good as any. A pen of this size will hold ten pairs of birds comfortably. The aperture for egress and ingress may be put in the most convenient place, and should be fitted with a bolting wire to prevent the birds getting out at will.

Next select your birds. If you want good ones I would recommend the purchase of old birds to breed from. Pay a visit to any genuine fancier who keeps birds for the love of them, and not entirely for profit. I never found such a one that was not pleased to show his birds, and to tell the distances the different birds had flown, together with their pedigree, and every particular connected with them. Select a pair to your fancy, and if for sale do not be to a shade as to price. Visit another fancier in like manner. Cut the birds down and cross-pair them, by which means you will avoid in-breeding, and stand a fair chance of getting good young ones, but this will by no means be a certainty. There cannot be a greater mistake than to suppose that because you mate good old birds the young produced will, as a matter of necessity, be good also. I have mated first-class birds for homing purposes, and the young produced have been worthless. If your birds do not "hit," you must change the old ones till they do, otherwise you will never have a pen of good Autwerps, as unless the birds possess the homing faculty to an average degree, they are not fair representatives of the breed, although they may have all the outward points required in a good bird. You may breed any colour; but Dun, Red Chequer, Blue, and Blue Chequer, are the only colours recognised by standard breeders. I prefer a pen of birds to match in colour, and if well matched it is difficult to decide which colour is the most attractive. The Light Duns, with bright red bars on the wings, and red necks, are certainly as handsome as any; Light Blues, with good black bars on the wings and tail, and rich metallic lustre on the neck, are also very pretty.

When you wish to try your young birds do not commence with them too early, let them be from four to five months old; they may then be thrown up a mile or two from home, and it will soon be seen which are likely to make good homing birds. If, when tossed up, a bird hangs about the place where it is loosed, flying low, and without spirit, ultimately dropping upon some convenient building, or with other birds, condemn it at once, and should it return home kill it without hesitation, however handsome it may be; if, on the contrary, the bird when tossed from the hand gets well up in the air, ranging wide, and flying resolutely, not taking notice of any birds that may be put up to it, there is every probability, if properly trained, that it will make a good bird.

I find it an excellent plan to clean out my birds' pens daily; it occupies but a few minutes, if a scraper similar to those used by pig-killers be kept for the purpose. Keep a barrel of sand near the pen, and after cleaning sprinkle a few handfuls on the bottom and at the front of the nesting places, this gives the pen a neat appearance, and conduces much to the comfort of the birds. Exercise your birds once daily—morning is the best time—and they will soar as high as Tumblers, flying from twenty to fifty minutes, and sometimes much longer; when they alight allow a little time for gritting, and to run the building, then whistle them in and feed, giving just as much as they will pick up freely; feed again about four o'clock, giving clean water daily. By these means your birds will be kept in constant health, and from their lively disposition and neat appearance will be a source of constant pleasure and amusement.—B. F. C.

CURE FOR ROUP.—I send you below a valuable receipt for the cure of roup in chickens. I have used it in over one hundred cases with complete success. The pill should be made as per enclosed sample. I consider the form of the preparation as important; it should be put into a gelatine capsule, otherwise it is very difficult to administer. Balsam copaiba 1 ounce, piperine 1 drachm, made into sixty pills, and give two or three every day. Wash.—A teaspoonful of sugar of lead, mixed with a

pint of water, for bathing the eyes two or three times a-day.—WALTER LAWRENCE.—(Poultry Bulletin.)

NORTHAMPTONSHIRE AGRICULTURAL SOCIETY'S SHOW.

REGARDLESS alike of trouble and heavy outlay, the Committee were determined to make the meeting held on the 15th and 16th inst. a success, and their anticipations were realised. A spacious tent and all the internal arrangements in the hands of Messrs. Turner, of Sheffield, brought an exhibition such as never before took place in Wellington. Old and young birds were shown in distinct classes. The adults were in deep moult; the chickens, on the contrary, being in the highest show trim possible. *Dorkings* and *Cochins* were unexceptionably good, and the cup-winners, as in most of the other classes, had to obtain their success in a severe competition. The *Ham-burgs* were, perhaps, the least praiseworthy classes in the whole Show; but the exhibitors of *Buenos Ayres* *Ducks*, *Laced Bantams*, and the various breeds of *French Fowls* deserve every expression of favour. *Pigeons* were shown in collections of three pens each, and certainly among the twelve pens exhibited by the four competitors were birds of great value and purity of breed. This portion of the Show proved a great attraction to the ladies, who, as the day was fine, congregated in the poultry tent in extraordinary numbers.

DORKINGS.—1 and 3, R. Wood, Clapton, Thrapstone. 2, H. Lingwood, Needham Market. **COCHINS.**—1, R. Wood, 2, H. Yardley, Birmingham. 3, J. Beasley, Chapel Brampton. **HENS.**—1, J. Longland, Grandon. 2, H. Lingwood. 3, H. R. Wood. 4, T. Furnaby, Pine-well. **CHICKENS.**—1, H. Lingwood. 2, J. Smith, Shillinglee, Petworth. 3, H. Yardley. 4, J. Longland. 5, J. K. Fowler, Ayles. **BIRDS.**—R. Sykes, Goldington, Kettering. 2, C. B. Charlis, Clendon, Kettering. 3, R. Wood. **POULTRY.**—1 and Cup, J. L. Malden. 2, J. Wood. 3, J. Longland. 4, R. W. B. Davies, Moseley Hall, Birmingham. 5, H. Yardley. **W. A. Taylor.** 1, J. K. Fowler. 2, J. Beasley. 3, J. W. A. Taylor. 4, W. A. Taylor. 5, J. K. Fowler. **HENS.**—1, W. A. Taylor. 2, H. Lingwood. 3, J. Stephens. 4, J. N. Peasley, Northampton. 5, T. Dufford. **CHICKENS.**—1, W. A. Taylor. 2, J. Stephens. 3, J. K. Fowler. 4, T. Dufford. 5, J. Beasley. **HAM-BURG (Any variety).**—1, B. Cox. 2, H. Yardley. **BANTAMS.**—1 and 2, M. Leno. 3, C. R. Heston. 4, J. Stephens. **ANY OTHER VARIETY.**—1, W. A. Taylor (Dark Bantam). 2 and 3, J. K. Fowler (French). **GEES.**—1, J. K. Fowler. 2, S. Deacon. **DUCK.**—1, J. K. Fowler. 2, J. K. Fowler. 3, J. Beasley. **FOWLS.**—1 and 2, H. R. Wood. 3, J. K. Fowler. **ANY OTHER FOWLS.**—1, M. Leno. 2, J. N. Peasley (Buenos Ayres). 3, J. N. Peasley (Buenos Ayres). 4, J. Goodlie (South Carolina). **TURKEYS.**—1, J. N. Peasley. 2, J. Craig, Fotheringhay, Oundle. **STEELE'S CLASS.**—1, W. A. Taylor. 2, C. Wright (Spanish). 3, H. Yardley. 4, S. Deacon (Aylesbury). 5, J. Smith (Grey Dorkings).

PIGEONS.—1 and 2, H. Yardley. 3, J. J. Sharp, Broughton, Kettering.

The Judges were Mr. Edward Hewitt, of Sparkbrook, Birmingham; and Mr. Tatham, of Kingshorpe, near Northampton.

AYLESBURY POULTRY SHOW.

This Show was held in a building as well suited for the purpose as could be desired, there being an abundance of light and plenty of ventilation and space. The competition throughout was very good, but in the *Aylesbury Ducks* and *Geese* unprecedented, as may be gathered from these facts:—The two rivals in these classes were determined to secure success if possible to their respective yards, and it is almost needless to state they were Mrs. Mary Seamons and Mr. John Fowler, both of Aylesbury. Such pens as they exhibited are in truth wonders. Mr. Fowler's first-prize *Geese* weighed 19 lbs. 4 ozs. the pair; Mrs. Seamons' second-prize 45 lbs. 11 ozs., and the same lady's third-prize 4 lbs. 13 ozs.; whilst 17 lbs. 8 ozs. nett the pair, with many others closely approaching to that weight, had to be satisfied with being highly commended. Both first and second-prize *Aylesbury Ducks* were 16 lbs. 12 ozs. per couple. Strange to say, there was not the slightest difference in weight, and Mrs. Seamons' birds, from being the best in feather, took precedence. Never were two such faultless couples placed in opposition; they were a show in themselves. Many extra couples almost as heavy were also exhibited. Fine weather and a very large attendance added much to the success of this year's Show.

DORKINGS (Any variety).—1 and Cup, L. Patton, Hillmore, Taunton. 2 and 3, C. Parle, Great Edder. 4, J. Longland, Grandon. 5, J. L. Lowndes, Hartwell. 6, T. W. Tapping, Hartwell. **BANTAMS (Any variety).**—1 and Cup, Lady Gwydyr, Stoke Park, Ipswich. 2, J. K. Fowler, Aylesbury. 3, Mrs. Astley, Chequers Court, Spanish. 4 and Cup, F. James, Fockham Rye. 5, W. R. Bull, Newport Pagnell. 6, Mrs. Allsopp, Hindlip Hall, Worcester. 7, W. A. Taylor, Stratford, Addington Park, Maidstone. 8, F. R. C. Nichols, Camberwell, H. Ebdon, Göttslock. **COCHINS.**—1 and Cup, Lady Gwydyr. 2, C. Sidgwick, Ryddesden Hall, Kettering. 3 and 4, W. H. Evans, Frington, Birmingham. 5, J. K. Fowler. **BIRDS.**—1 and Cup, C. Sidgwick. 2 and 3, J. K. Fowler. 4, Lord Chesham, Latimers. **GAME.**—*Black-breasted and other Reds.*—1 and Cup, J. Lamug, Cowburn, Spalding. 2 and 3, S. Matthews, Stowmarket. 4, J. Lamug, Gloucester. *Any other Colour.*—1 and 2, D. Matthews, Stowmarket. 3, J. Lamug. **FRENCH (Any variety).**—1 and Cup, J. J. Malden, Biddlewade (Creve-Geur). 2, Hon. H. W. Fitzwilliam, M.P., Wentworth Woodhouse (La Fochelle). 3, W. A. Taylor. 4, W. A. Taylor. 5, W. R. Bull. 6, W. R. Bull. 7, J. K. Fowler. 8, J. K. Fowler. 9, J. K. Fowler. 10, J. K. Fowler. 11, J. K. Fowler. 12, J. K. Fowler. 13, J. K. Fowler. 14, J. K. Fowler. 15, J. K. Fowler. 16, J. K. Fowler. 17, J. K. Fowler. 18, J. K. Fowler. 19, J. K. Fowler. 20, J. K. Fowler. 21, J. K. Fowler. 22, J. K. Fowler. 23, J. K. Fowler. 24, J. K. Fowler. 25, J. K. Fowler. 26, J. K. Fowler. 27, J. K. Fowler. 28, J. K. Fowler. 29, J. K. Fowler. 30, J. K. Fowler. 31, J. K. Fowler. 32, J. K. Fowler. 33, J. K. Fowler. 34, J. K. Fowler. 35, J. K. Fowler. 36, J. K. Fowler. 37, J. K. Fowler. 38, J. K. Fowler. 39, J. K. Fowler. 40, J. K. Fowler. 41, J. K. Fowler. 42, J. K. Fowler. 43, J. K. Fowler. 44, J. K. Fowler. 45, J. K. Fowler. 46, J. K. Fowler. 47, J. K. Fowler. 48, J. K. Fowler. 49, J. K. Fowler. 50, J. K. Fowler. 51, J. K. Fowler. 52, J. K. Fowler. 53, J. K. Fowler. 54, J. K. Fowler. 55, J. K. Fowler. 56, J. K. Fowler. 57, J. K. Fowler. 58, J. K. Fowler. 59, J. K. Fowler. 60, J. K. Fowler. 61, J. K. Fowler. 62, J. K. Fowler. 63, J. K. Fowler. 64, J. K. Fowler. 65, J. K. Fowler. 66, J. K. Fowler. 67, J. K. Fowler. 68, J. K. Fowler. 69, J. K. Fowler. 70, J. K. Fowler. 71, J. K. Fowler. 72, J. K. Fowler. 73, J. K. Fowler. 74, J. K. Fowler. 75, J. K. Fowler. 76, J. K. Fowler. 77, J. K. Fowler. 78, J. K. Fowler. 79, J. K. Fowler. 80, J. K. Fowler. 81, J. K. Fowler. 82, J. K. Fowler. 83, J. K. Fowler. 84, J. K. Fowler. 85, J. K. Fowler. 86, J. K. Fowler. 87, J. K. Fowler. 88, J. K. Fowler. 89, J. K. Fowler. 90, J. K. Fowler. 91, J. K. Fowler. 92, J. K. Fowler. 93, J. K. Fowler. 94, J. K. Fowler. 95, J. K. Fowler. 96, J. K. Fowler. 97, J. K. Fowler. 98, J. K. Fowler. 99, J. K. Fowler. 100, J. K. Fowler. 101, J. K. Fowler. 102, J. K. Fowler. 103, J. K. Fowler. 104, J. K. Fowler. 105, J. K. Fowler. 106, J. K. Fowler. 107, J. K. Fowler. 108, J. K. Fowler. 109, J. K. Fowler. 110, J. K. Fowler. 111, J. K. Fowler. 112, J. K. Fowler. 113, J. K. Fowler. 114, J. K. Fowler. 115, J. K. Fowler. 116, J. K. Fowler. 117, J. K. Fowler. 118, J. K. Fowler. 119, J. K. Fowler. 120, J. K. Fowler. 121, J. K. Fowler. 122, J. K. Fowler. 123, J. K. Fowler. 124, J. K. Fowler. 125, J. K. Fowler. 126, J. K. Fowler. 127, J. K. Fowler. 128, J. K. Fowler. 129, J. K. Fowler. 130, J. K. Fowler. 131, J. K. Fowler. 132, J. K. Fowler. 133, J. K. Fowler. 134, J. K. Fowler. 135, J. K. Fowler. 136, J. K. Fowler. 137, J. K. Fowler. 138, J. K. Fowler. 139, J. K. Fowler. 140, J. K. Fowler. 141, J. K. Fowler. 142, J. K. Fowler. 143, J. K. Fowler. 144, J. K. Fowler. 145, J. K. Fowler. 146, J. K. Fowler. 147, J. K. Fowler. 148, J. K. Fowler. 149, J. K. Fowler. 150, J. K. Fowler. 151, J. K. Fowler. 152, J. K. Fowler. 153, J. K. Fowler. 154, J. K. Fowler. 155, J. K. Fowler. 156, J. K. Fowler. 157, J. K. Fowler. 158, J. K. Fowler. 159, J. K. Fowler. 160, J. K. Fowler. 161, J. K. Fowler. 162, J. K. Fowler. 163, J. K. Fowler. 164, J. K. Fowler. 165, J. K. Fowler. 166, J. K. Fowler. 167, J. K. Fowler. 168, J. K. Fowler. 169, J. K. Fowler. 170, J. K. Fowler. 171, J. K. Fowler. 172, J. K. Fowler. 173, J. K. Fowler. 174, J. K. Fowler. 175, J. K. Fowler. 176, J. K. Fowler. 177, J. K. Fowler. 178, J. K. Fowler. 179, J. K. Fowler. 180, J. K. Fowler. 181, J. K. Fowler. 182, J. K. Fowler. 183, J. K. Fowler. 184, J. K. Fowler. 185, J. K. Fowler. 186, J. K. Fowler. 187, J. K. Fowler. 188, J. K. Fowler. 189, J. K. Fowler. 190, J. K. Fowler. 191, J. K. Fowler. 192, J. K. Fowler. 193, J. K. Fowler. 194, J. K. Fowler. 195, J. K. Fowler. 196, J. K. Fowler. 197, J. K. Fowler. 198, J. K. Fowler. 199, J. K. Fowler. 200, J. K. Fowler. 201, J. K. Fowler. 202, J. K. Fowler. 203, J. K. Fowler. 204, J. K. Fowler. 205, J. K. Fowler. 206, J. K. Fowler. 207, J. K. Fowler. 208, J. K. Fowler. 209, J. K. Fowler. 210, J. K. Fowler. 211, J. K. Fowler. 212, J. K. Fowler. 213, J. K. Fowler. 214, J. K. Fowler. 215, J. K. Fowler. 216, J. K. Fowler. 217, J. K. Fowler. 218, J. K. Fowler. 219, J. K. Fowler. 220, J. K. Fowler. 221, J. K. Fowler. 222, J. K. Fowler. 223, J. K. Fowler. 224, J. K. Fowler. 225, J. K. Fowler. 226, J. K. Fowler. 227, J. K. Fowler. 228, J. K. Fowler. 229, J. K. Fowler. 230, J. K. Fowler. 231, J. K. Fowler. 232, J. K. Fowler. 233, J. K. Fowler. 234, J. K. Fowler. 235, J. K. Fowler. 236, J. K. Fowler. 237, J. K. Fowler. 238, J. K. Fowler. 239, J. K. Fowler. 240, J. K. Fowler. 241, J. K. Fowler. 242, J. K. Fowler. 243, J. K. Fowler. 244, J. K. Fowler. 245, J. K. Fowler. 246, J. K. Fowler. 247, J. K. Fowler. 248, J. K. Fowler. 249, J. K. Fowler. 250, J. K. Fowler. 251, J. K. Fowler. 252, J. K. Fowler. 253, J. K. Fowler. 254, J. K. Fowler. 255, J. K. Fowler. 256, J. K. Fowler. 257, J. K. Fowler. 258, J. K. Fowler. 259, J. K. Fowler. 260, J. K. Fowler. 261, J. K. Fowler. 262, J. K. Fowler. 263, J. K. Fowler. 264, J. K. Fowler. 265, J. K. Fowler. 266, J. K. Fowler. 267, J. K. Fowler. 268, J. K. Fowler. 269, J. K. Fowler. 270, J. K. Fowler. 271, J. K. Fowler. 272, J. K. Fowler. 273, J. K. Fowler. 274, J. K. Fowler. 275, J. K. Fowler. 276, J. K. Fowler. 277, J. K. Fowler. 278, J. K. Fowler. 279, J. K. Fowler. 280, J. K. Fowler. 281, J. K. Fowler. 282, J. K. Fowler. 283, J. K. Fowler. 284, J. K. Fowler. 285, J. K. Fowler. 286, J. K. Fowler. 287, J. K. Fowler. 288, J. K. Fowler. 289, J. K. Fowler. 290, J. K. Fowler. 291, J. K. Fowler. 292, J. K. Fowler. 293, J. K. Fowler. 294, J. K. Fowler. 295, J. K. Fowler. 296, J. K. Fowler. 297, J. K. Fowler. 298, J. K. Fowler. 299, J. K. Fowler. 300, J. K. Fowler. 301, J. K. Fowler. 302, J. K. Fowler. 303, J. K. Fowler. 304, J. K. Fowler. 305, J. K. Fowler. 306, J. K. Fowler. 307, J. K. Fowler. 308, J. K. Fowler. 309, J. K. Ireland. c, T. Kingsley. (Special Class).—1 and Cap. Mrs. M. Smith, Haddenham. 2, J. Hedges, Aylesbury. 3, J. Funge, Long Marston. *hc*, Lord Chesham; J. Funge. c, Mrs. C. Oakley, Astrop, near Trinz. *Rouen*.—1 and Cap. Mrs. M. Seamons. 2, L. Patton. 3, F. Parlett, Great Baddow. *hc*, E. Leech; Mrs. M. Seamons; L. Patton; J. K. Fowler, c, J. L. Lowndes. *Any other Variety*.—1, S. Burn, Whitby, Yorkshire. 2, J. Saunders, Sainsbury, Devizes (Buenos Ayrens). 3, M. Leno (Carolina). *GEESSE* (Any variety).—1 and Cap. J. K. Fowler. 2 and 3, Mrs. M. Seamons, *hc*, E. Leech; J. Denchfield, Hurston; J. K. Fowler. c, W. Parrot, Ford. *TERKEYS* (Any variety).—1 and Cap. E. Leech. 2 and 3, Lord Chesham. *hc*, J. K. Fowler. c, Capt. Dauncey, High Wycombe. *PHEASANTS* (Any variety).—1, 2, and 3, J. K. Fowler. *hc*, M. Leno. *SELLING CLASS*.—1, 2, and 3, J. K. Fowler (Dark Brahma and Grey Geese), 3 and *hc*, Mrs. M. Seamons (Silky Fowler).

PIGEONS.—*Carriers* (Any variety).—1 and 2, H. Yardley, Birmingham. *Pouters* (Any variety).—1, H. Yardley. 2, J. K. Fowler. *Fantails* (Any variety).—1 and 2, H. Yardley. *Any other Variety*.—1, H. Yardley (White Owls). 2, Lady F. Bushby, (B'ne Runts). *hc*, H. Gurney, jun., Aylesbury; J. K. Fowler.

Mr. Edward Hewitt, Sparkbrook, near Birmingham, was the Judge.

(From a Correspondent.)

This was the twelfth Show in connection with the Royal Buckinghamshire Agricultural Association. The entries were very small, especially the Pigeons, in some classes there being only two entries for a similar number of prizes. The few entries were no doubt caused by the heavy entry fees—viz., 5s. per pen, and another 5s. for membership to the Association. This appears rather high for a chance of winning a ten-shilling prize. On referring to the catalogue I find no less than fourteen silver cups or pieces of plate, each forming the first prize for as many different classes. These were all given by patrons or friends, so that the Poultry Show must form a very profitable source of income to the Association; and I would suggest to the Committee that they should do away with the five-shilling membership, throw the competition open to all, and they would then get far more numerous entries.

The *Dorkings* stood first, and of these there were some very good birds. Those in the cup pen were in excellent feather and condition, but I fancied the cock had a wry tail. The second-prize birds were also good, but I should not like to say the third were this year's birds; if so, they must have been hatched very early on New-year's morning. The cup for *Brahmas* was won by a splendid pair of Dark, the second prize went to Light. *Spanish* were a capital lot, the best I have seen this year. The pullet in the cup pen was very forward for one of this year's birds. The second-prize cock was matched with an inferior pullet, and he also must have been hatched very early this year. I did not like the award of the third prize, there was a decidedly better pair amongst those which were only commended; and here, perhaps, I may remark that judges frequently give prizes to the best cock when it is offered for the best cock and hen, often entirely ignoring the latter. The cup pen of Buff *Cochins* were a wonderful pair of birds, beautiful in colour and feather, and excellently shown. The Partridge were also good, especially the first and second-prize pens. *Game* were hardly so good as might have been expected. Of *French* fowls there was a very fair entry, and some of the birds were very superior. Black *Crève-Coeurs* were first. A good pair of *Houdans* arrived too late for competition, or they would certainly have obtained a prize. *Hamburghs* were few and of no particular merit. As might be expected, the *Bantams* were a very poor class when we find, as we do here, the many different varieties of this very popular class all jumbled together. The first prize went to a good pen of *Sebrights*, and there was nothing else in the class worthy of notice.

Ducks were a splendid lot, the first and second prize *Aylesbury* Ducks being of exactly the same weight; but the first were in fair feather, and consequently won the cup. *Rouen* Ducks were likewise good, and there was an excellent drake in the cup pen. The *Geese* were very remarkable in size and weight, but heavy in moult. *Turkeys* were fair. The *Pheasants* were a very pretty class, and created much interest amongst the numerous visitors. The *Selling Class* was a failure; five entries—one pen empty, and three prizes. The *Pigeons* were a wretched entry as regards numbers. Mr. Yardley took all the first and most of the second prizes.

WELLINGTON (SALOP) POULTRY SHOW.

In again bringing before the neighborhood this Show as a candidate for public favour, the Committee wisely determined to make it entirely a show of poultry hatched in the present year, and most of our readers who happened to be present were well pleased at finding at Wellington some of the very best birds in the kingdom. There was not a single class that was not well represented, saving one, which, singularly enough, was that for the best *Game* cockerel. Here there was not a single entry. The *Game* fowls shown in pairs were, on the contrary, excellent. The *Hamburghs* of every kind were extraordinarily good, though a pen or two were disqualified on account of adult specimens being exhibited as chickens, evidently rather from a misunderstanding of the prize schedule than from willing imposition. The "Extra Variety" class was one of the best ever exhibited, and the largest in the Show; so good indeed was it, that every pen that remained after the two general premiums were awarded was highly commended. No prizes for *Pigeons* were offered, yet the Show was singularly well supported and attractive.

GAME.—*Black or Brown Red*.—1, J. Platt, Swanlow. 2, Duke of Sutherland, *hc*, G. Lind. *Any other Variety*.—1, J. Platt. 2, W. Dunning, Newport. *hc*, G. Lind. *DORKINGS*.—1, E. Shaw, Plas Wilnot, Oswestry. 2, Mrs. E. Williams, Henllys, Berriew. *hc*, J. Edwards, Epton; A. Darby, Stanley Hall, Bridgmont, SPANISH (Black).—1, R. Hulso, Wray Green, Cheshire. 2, E. Shaw. *HAMBURGHS*.—*Gold or Silver-splangled*.—1, Duke of Sutherland. 2, J. C. Smith,

Wellington. *hc*, C. Parsons, Wolverhampton; T. Hassall, Adderley, Market Drayton. *Gold or Silver pencilled*.—1 and 2, Duke of Sutherland. *ANY OTHER VARIETY*.—1, Duke of Sutherland (Black Hamburgs). 2, Mrs. E. Williams (Crève-Coeur). *hc*, H. Yardley (2); A. Darby (2); J. G. Pearson, Market Drayton; A. D. Payne, Shrewsbury. *DUCKS*.—1, J. Platt. 2, T. Radcliffe, Newport. c, St. J. C. Charlton (2). *GEESSE*.—1, E. Shaw. 2, J. Edwards. c, T. W. Jones, Wellington. *TERKEYS*.—1 and 2, T. W. Jones.

The Judge was Mr. Edward Hewitt, of Sparkbrook, Birmingham.

NATIONAL PERISTERONIC SOCIETY.

This Society, which numbers amongst its members some of the leading breeders of Great Britain, held its first meeting for the season at the Freemason's Tavern, Great Queen Street, London, on the 20th inst., and if we are to judge by the quality and quantity of young birds shown, this has been a very successful season. As this is not a competitive Show, we were spared the complaints of disappointed exhibitors; but were glad to learn, on the other hand, there is every prospect of the forthcoming Crystal Palace Show, in the Cattle Show week, being second to none, as in one corner of the room four of its members promised five five-guinea pieces of plate, and no doubt others will follow their example. Amongst the birds shown were a splendid lot of young *Carriers* from Messrs. Ord and Hedley, with that stately carriage and prominent eye that at once stamps this species as the king of Pigeons. The latter gentleman also exhibited a pair of old birds, which, as a visitor said, would, if publicly exhibited, be a show in themselves. The Honorary Secretary, Mr. P. H. Jones, showed a good pen of *Pouters*, also some of the best *Trumpeters* since their parents were shown here three years ago. He also contributed some other beautiful Toys, consisting of *Turbits*, *Nuns*, *Maggies*, *English Owls*, and *Barks*, aided in the last species by half a dozen from Mr. Hedley. Messrs. Else and Betty showed some good *Dragoons*, a paper respecting which will be read by Mr. Tegetmeier at the next meeting on the 4th of October. This gentleman sent a very pretty and good lot of *Antwerps* and *Carriers*. Last, but not least, were two pens of *Almonds* and *Kites* from Messrs. Jayne and Ford, which we have no doubt will be heard of again.

WHITBY CANARY SHOW.

My wife was not quite ready, and I was waiting at the door. "No hurry, sir, no hurry. I can do it in six minutes, and it wants ten minutes yet, ten minutes good. Plenty of time, sir, pl-e-n-t-y of time." That's what cabby said. "William, where is the key of the black portmanteau?" That's what my wife said. No hurry, indeed! The position was critical. Given ten minutes to reach the station, and a willing cabby open to back himself for a small amount to do it in six. Required to find the key of the black portmanteau; to unlock it (itself a feat only to be attempted when the lock is in a good humor); to stuff it with articles too large to go in it, and more of them than it would hold, even if they would; to go through the horrors of locking it, and getting the key out of the keyhole without unlocking it again; to decide whether somebody's back hair was all right; to do this and catch the train all in four minutes without losing your temper, that's the problem. Postulates—Let it be granted that the key of the black portmanteau can never be found when wanted, and that two bodies cannot occupy the same space. Axiom—when a thing has happened frequently before, you needn't be surprised at its happening again. But we just did it. Cabby had orders to force the pace, which he did, and, making a brilliant "finish," he beat time with a little in hand.

We went by the night train, and though it was full moon (a remarkable coincidence, but I only mention it as a fact), there was not a great deal to be seen. Rosebery Topping and the Clevelanders were sleeping with grey nightcaps on. Night was turned into day as we sped through the ironstone district about Glaisdale. The tall blast furnaces were some of them belching out flames, casting a lurid glare over the surrounding woods; others discharging streams of liquid fire, while demons and sprites flitted about in all directions feeding huge fires, cramming the capacious maw of some immense furnace, or trotting off to "tip" a cauldron of molten slag over some mountain of an embankment where thousands of tons had gone before, and down whose sides it crept with stealthy step, a river of fire.

Arrived at Whitby, we were most kindly received by the Honorary Secretary, James Wilkinson, Esq., and Mrs. Wilkinson, and one more strong link was welded to the chain which my connection with the Canary and "our Journal" has forged about me. As I was not required at the Show till about eleven o'clock we had a drive, and "did" the place. It was a very rapid "do," and I could only get a passing glance, but my recollection of Whitby is going up a very steep street in a carriage with two ladies in front, who seemed every now and then in imminent danger of falling forwards into my lap; a sweep round a fine terrace on the cliff; then a winding descent to the quay; am-

phibious creatures in oilskins salting barrels of herrings; across a short drawbridge at the entrance to the harbour; along a narrow street by the river side where, fortunately, we met no other conveyance, or else one or the other must have been compelled to back out; up a steep ascent almost on my back, and we were at the ruins of the old abbey on the brow of the hill, forming the south side of the valley of the Esk. A hurried walk round the churchyard which stands on the verge of the cliff, a peep over the edge of the sea, the piers, and the town at my feet, and we commenced our descent, the horse foreshortened till his ears seemed growing in the neighbourhood of his tail. To prevent accident I shored myself up with my umbrella, and got down with no further inconvenience than a strong tendency to slide off my seat. A zigzag crawl up the other side landed me at the door of the Congress Hall, where the Show was held, and as there were a few minutes to spare while the finishing touches were being put to the arrangement of the birds, I occupied the time in inspecting the horticultural department.

The show of plants was not large, I mean not very large, but there were some lovely specimens, the arrangement being on the whole very good. The centre stage appropriated to this branch had a very imposing effect. There were excellent collections of stove and greenhouse plants, ornamental-foliaged plants, small Conifers, Lilliums, hardy herbaceous specimen plants in flower or fruit well-fruited Vines in pots, Tricolored Geraniums, Ferns, and a host of other things. On either side was a long table, one for cut flowers, and the other for fruit. Dahlias, Asters, French and African Marigolds (real Jonques), Verbenas, Gladioli, &c., were excellent. A table placed transversely at the end of the Hall was filled with choice bouquets for the hand, ball-room or wedding, while the fruit table was decorated with groups of flowers and fruit in ornamental stands for the dining table. The collection of fruit was splendid, comprising White, Black, and Frontignan Grapes, in single bunches and trays of three; Pines, Melons, Peaches, Nectarines, Apricots, Plums, in variety; Apples and Pears without end; Currants as large as small Grapes; Gooseberries, and trays of collections. Looking at the fruit I sympathised with poor Eve. The vegetables were first-class, and on a gigantic scale—Cucumbers 30 inches long, and well grown; Celery enormous; Onions, Carrots, Parsnips, Turnips, in perfection; Potatoes, of all shapes; Cabbages, by the cubic yard, I was going to say; Peas, capital; ditto Beans, and Vegetable Marrows in all stages. The cottagers' groups, too, were very creditable, and in some cases would not have disgraced a gentleman's gardener.

The exhibition of Canaries has an interest which attaches to no other show, inasmuch as it is the first of the season, and exhibitors and fanciers in general look to Whitby to mark the advent of youngsters destined to play a prominent part in the Canary world. Last year this was notably the case, but on this occasion, owing to the late moult, there were not so many new stars discovered. Many of the best of our All-England men sent entries, and before I have a little chat with them allow me to shake hands with them all round. Mr. Moore (old warrior), and your other half, Mr. Wynn; Mr. Bexson (I've never seen you, and I often wonder what you're like?); Mr. Irons (the crested hen has come out very fresh again); Mr. Hawman (what got the Lizard cock? it wasn't there); Mr. Bulmer (she's a bonny little hen, rather small); Mr. Simpson, Mr. J. N. Harrison, Mr. Barwell, Mr. Adams, Mr. Burton, Mr. Wales, Mr. Fairclough, everybody—how do you do? I congratulate you on the opening of the season, hope you have all had good luck. Was it a good show? Very good indeed, and the arrangements not to be excelled. The Jonques were fair birds, but there are better to come. Irons won easily. Simpson has got into a good seam; his first-prize mealy bird will give you all some trouble this season, if he is only brought out in condition to the end. His six Jonques in Class 19 were six very nice level birds. Whitty will hold its own this year. The marked classes contained some excellent birds. Moore's even-marked Yellow is bad to beat, but the colour is not so pure a Jonque as I should like. Adams's two, 32 and 33, were fine lusty birds, of good size and capital quality. I had some difficulty in coming to a decision in the Even-marked Meales. Bexson's bird, 41, was the nearest to the type, but second and third were nice birds also. In the Ticked classes the first birds were good, and very cheap at the catalogue price—plenty of quality. With the exception of Irons's Buff Hen I cannot praise the Crests—there was too much "copy" in some of them. The crest is imported from other varieties, I admit, but breed out the distinctive features of those varieties a little more

before calling them "Norwich." You know as well as I do that a Norwich bird is not a foot long, nor does it stand nearly as upright as a Belgian. Belgians were very backward in condition. No 76 made one demonstration of what he was capable of doing, and then rolled himself into a ball, the picture of misery. Bulmer's Hen, No. 78, and Bexson's 81 were most forward in the Buff class, and performed best. The Yorkshire were as usual mixed up with Norwich birds, some of which would not have disgraced Class 2. The winning birds were lengthy and asymmetrical. Irons had it all his own way in Cinnamons, especially in the Buffs, Bexson not being in such form as last year, and Moore not making any decided mark. The Lizards were certainly not the best which will be sent out this year; but 117 (James Taylor) was a bird above the average, and Mr. Harrison had a useful one in each class. Greens were poor excepting the first, which was well through, and of good size and colour. Atkinson generally hunts up one or two good Greens. 129, Mark Burton, will see a better day. Judging the Mules resolved itself into a mere question of condition, none being through the moult. The district prizes were well contested, Mr. Simpson and Mrs. J. Wilkinson exhibiting birds of superior quality.

Another month will find us in the middle of the show season, at a time when birds look their best. In this district, Scarborough, North Ormesby, Middlesbrough, Darlington, Thirsk, Stockton, Stokesley, Newcastle, and other shows follow in quick succession. They are all under the management of enthusiastic fanciers, and deserving of strong support. At most of them I shall if all be well be present, possibly at all, and hope I shall see large entries of first-class birds.—W. A. BLAKSTON.

SWARMING.

In my remarks on swarming, in page 51 of "our Journal," I stated that I had never seen an old queen, that was prevented by unfavourable weather from going off with a swarm, destroy her own royal offspring in the cells in which they were maturing. Whilst doing so I had no intention of affirming that such an occurrence had not been observed by others. Mr. Taylor, in his manual on bee-keeping, when speaking of the issue of a swarm being prevented by weather, remarks, "The reigning sovereign will avail herself of this compulsory detention in severally destroying the young princesses as they are matured. An old queen is permitted by the bees to do this, but it is otherwise with a young one till a later stage." In this account of the matter other authorities agree, but I am not satisfied with the grounds on which their conclusions are founded. Huber, in one of his experiments, placed three royal cells in a hive containing a fertile queen, which were immediately pounced upon and pierced by the jealous sovereign. In another experiment immediately after the departure of a first swarm he found seven royal cells "close at the top, but open at the side, and quite empty."

Now, it was natural to conclude that these royal cells had been destroyed by the old queen, but perfect evidence of the fact is wanting. They might have been destroyed by a young queen which had escaped from her cell. That young queen might have gone off with the swarm, or fallen a sacrifice after her work of destruction in a mortal struggle with her own mother. It does not appear that the old queen was seen to destroy the royal cells. She might or she might not have done so; and this is what I would like to know, Whether any apiarian has had indubitable evidence of the queen, through swarming being delayed, deliberately setting to work to destroy the royal cells of her maturing offspring? That a queen introduced to a hive containing royal cells will destroy them, or that royal cells introduced into her hive will be torn open by her, is sufficiently proved by the experiment of Huber first referred to, and I can also imagine circumstances in which she would destroy cells tenanted by herself. For example, if she were removed a couple of days from her hive, and again restored to her dwelling, the destruction of royal cells might take place. This was inferentially proved by me in the course of last summer. On July 23rd a Woodbury box threw a large top swarm. The swarm was located in a common straw hive for thirty hours, and placed at some distance from the parent stock. Then about sunset the bees were all shaken out on to the ground, and made once more to re-enter their hive. As soon as settled the central hole of the parent stock was opened and the skep containing the swarm placed over it. I argued that the queen would probably remain in the skep for a day or two before descending to the parent stock, and that if she did she would

be unprepared to find royal cells, and in consequence destroy them. This probably happened, for no further swarming took place, but what was of most consequence was the fact that in the course of a month about 40 lbs. of beautiful honey were collected in the skep, there being only some two dozen cells with brood in them in the central comb. Had the skep with swarm not been converted into a super, it would most likely have been found to contain less than a third of the amount yielded in this way.—R. S.

THE NEW METHODS OF CONTROLLING THE FERTILISATION OF THE QUEEN BEE.

As several articles have appeared in your Journal upon the subject of controlling the fertilisation of the queen bee, I will add my testimony to that which has already been given in your pages. Early in June I had three young Italian queens (all hatched at the same time) at the head of three hives. One of these was left at liberty from the first, and was duly impregnated; the second was imprisoned with a number of drones for two days, as recommended by Mrs. Tupper; but as neither the queen nor drones afforded positive or negative proof of fertilisation having been effected, I allowed the queen to descend into the hive and follow her own natural instinct. She soon availed herself of her liberty, and proved a very fine and fertile queen. The third queen was confined for four or five days, but with like results, and when set at liberty took flight with difficulty, and never returned. The Kähler process has in like manner proved unsatisfactory. Some queens so treated have turned out drone-breeders, and some have been lost. Only one out of several secured a genuine impregnation, and she was nearly a month old before she began to lay.—J. E. B.

SINGULAR CASE OF ROBBING.

A CORRESPONDENT of an American paper says:—"I had a curious case of robbing last season. Two swarms of about equal strength commenced robbing each other; I tried my usual remedy, effectual in nearly every instance, which is a small rag saturated with camphor or spirits of turpentine placed on each side of the entrance, but it had no effect. I then carried one swarm into the cellar at night, and kept it there three days, and on setting them out they went at it again. I then set one swarm in the cellar three days, then set it out, and carried the other in for three days; and on setting them out they went at their old game. I then exchanged the stands, but it had no effect. There was no quarrelling between the swarms, so I let them work, and examined them every evening, and if one swarm had more than their share of honey I exchanged combs, and so kept them all right; but both swarms thought they were doing an extra large business, and consequently went to breeding very rapidly, more so than any other swarm I had. But they consumed a large quantity of honey, and gathered apparently double the quantity of pollen that any other swarm in my yard did during the same time. They kept up their practice until they commenced gathering honey abundantly, and then gradually ceased robbing altogether. That is the first case of the kind I ever knew.—E. G."

OUR LETTER BOX.

KEEPING POULTRY IN A CONFINED SPACE (M. W.).—The space is a small one, but with the arrangements you make you may easily keep two birds in health. In the way of green food, we advise you to give it every day instead of every alternate day, and to omit the cabbage; substitute seeds of growing grass, cut with plenty of earth. The fowls will tear them to pieces, eat the grass, and find all sorts of food and medicine in the fresh mould. Let them have their liberty every Sunday—it is better than nothing. You can buy such seeds as you require of the men who sell turves for Larks, and groundsel for singing birds.

POINTS OF CREVE-CŒURS.—SELECTING EGGS TO PRODUCE COCK OR HEN CHICKENS (E. E. F.).—If we go to the strict requirements of the breed, we should tell you the comb should present nearly the appearance of a cloven heart "Cœur Creve." In some birds it is early developed; in others it is very late; but the older the bird the larger the comb will be. The same may be said of the pullets. Two birds of the same age will show, one a bright red comb, the other no appearance of one; it merely proves that one is more forward than the other. They should be top-knotted and bearded, have short legs and square bodies. The legs should be black. The top-knots should be black, but as the pullets become hens white feathers appear in them, and in old birds they are nearly white. It is no proof of degeneracy, but, if possible, it should be avoided in show birds. We have tried the egg question by ourselves, and with the "learned" in such matters. We always failed. It is said the great success of "Francis Moore, Physician," with his "Vox Stellarum," or "Loyal Almanack," arose from the fact that when once he was walking up and down the room in a brown study, and his clerks were compiling the Almanack

for the following year, the subordinate who had charge of the month of June, asked him every time he passed, "Weather, sir, for the 3rd of June." Francis Moore bore it as long as he could. He showed his temper, it took no effect, and as he passed the desk he heard for the two hundred and eighty-first time, "Weather, sir, for the 3rd of June." We object to print the first part of the speech, but the end was, "— you, sir, frost and snow." It did freeze, and there was snow on that day. He was a made man. A chance made him, and the same may be said of the fortunate person who warranted thirteen eggs to produce twelve pullets and a cock. Fortune favours the bold. Ask him to try again. A friend of ours by no means distinguished as a shot, went as an amateur to a rifle corps target, and on being asked to take a shot, made a careless bull's eye at 600 yards. He was wise, he merely remarked it was an easy range and went away. We know a man who deals in eggs in the season. He told us he received postage stamps for 5s., and a request that he would forward eggs warranted to produce a cock and three hens, common Pheasants. We forgot to say it is very desirable the Creve-Cœur cocks should be entirely black, but like all black cocks, they will as they grow older throw coloured feathers. Yellow may be overlooked. Red are disqualifications.

COMMENCING PIGEON-KEEPING (R. M.).—The place you propose would do well enough for any but high-class delicate birds. We would advise you to start with Long-faced Tumblers, say Baldheads, or Blue Dragons or Antwerps; these are quite as prolific, bringing many pairs a-year, as common or cross-bred birds, just as healthy, and infinitely prettier. If you obtained a few young ones now they would pair and breed early in the spring. We are afraid that no Pigeons whatever, however common, pay at what you term "pot prices" if you have to buy all their food. But if you kept, say Dragons, they are strong of wing, and would, as you live in a town, soon get into the streets and pick up part of their living. You could also get charlock of the farmers, but it is an awful weed in the garden, and will become a nuisance if it be taken up with the manure to the manure heap. Young birds breed best.

INSECTS IN BACON (C. P.).—They are the common bacon beetles, Dermestes lardarius and their larvæ.—W.

METEOROLOGICAL OBSERVATIONS In the Suburbs of London for the week ending September 20th.

Table with columns: DATE, BAROMETER (Max., Min.), THERMOMETER (Air: Max., Min.; Earth: 1 ft., 2 ft.), Wind, Rain. Data for Wed., Thurs., Fri., Sat., Sun., Mon., Tues., and Mean values.

- 14.—Very fine; fine but cloudy; clear, starlight.
15.—Dense fog; very fine; foggy, fine at night.
16.—Foggy; fine, slight fog; clear and fine.
17.—Densely overcast throughout; heavy clouds.
18.—Densely overcast; fine, slightly overcast; densely overcast.
19.—Dense fog; densely overcast; clear and fine.
20.—Foggy; very fine; clear and fine.

COVENT GARDEN MARKET.—SEPTEMBER 21.

A VERY slack demand and a large supply do not admit of any improvement in prices; in fact, many articles have been left at lower offers than last week, the growers being anxious to effect sales. Potatoes are in fair request, and command about last week's quotations.

FRUIT.

Table listing fruit prices: Apples, Apricots, Chestnuts, Cherries, Currants, Black Currants, Fig, Filberts, Gooseberries, Grapes, Lemons, Melons, Mulberries, Nectarines, Oranges, Peaches, Pears, Pine Apples, Plums, Quinces, Raspberries, Strawberries, Walnuts.

VEGETABLES.

Table listing vegetable prices: Artichokes, Asparagus, Beans, Broad Beans, Beet, Broccoli, Brussels Sprouts, Cabbage, Capsicum, Carrots, Cauliflower, Celery, Coleworts, Cucumbers, Endive, Fennel, Garlic, Herbs, Horseradish, Leeks, Lettuce, Mushrooms, Mustard & Cress, Onions, Parsley, Parsnips, Peas, Potatoes, Kidney Potatoes, Radishes, Rhubarb, Savoy, Sea-kale, Shallots, Spinach, Tomatoes, Turnips, Vegetable Marrows.

From observations taken near London during the last forty-three years, the average day temperature of the week is 63.7, and its night temperature 42.9. The greatest heat was 80°, on the 5th, 1834; and the lowest cold 23°, on the 29th, 1842; and 30th, 1836. The greatest fall of rain was 1.68 inch.

CLIMBING FERNS.—No. 1.

HERE are a few Ferns to be met with in cultivation which do not in the majority of collections display their beauties to the greatest advantage: I allude to those few species of scandent habit belonging to several genera, many of which have the power of extending their fronds to an indefinite length. That these plants do not lack beauty I am positive, because I have grown all the kinds here enumerated into good specimens, and yet how

seldom do we see them properly treated; and let me add, in passing, these very plants can be made prominent objects in a fernery, diversifying its features, enhancing considerably its beauty, and thus increasing its interest. With the hope, therefore, that a few remarks upon these climbing Ferns may not be unwelcome, I purpose briefly describing the various species, and the best method of cultivating them, commencing with the genus

LYGODIUM.

As a genus this is characterised by its twining scandent fronds, which have the peculiarity of extending themselves to an indefinite length; the pinnæ are usually in pairs or are palmately lobed, but sometimes they are pinnatifid; the veins are forked and free, the sporangiferous receptacle is situated at the margin; and the sori stand out beyond the edges like little spikes, giving the fruiting fronds a distinct and very handsome appearance. In a state of nature these plants are mostly found growing in stiff loamy soil, and nearly always in the vicinity of shrubs or low bushes, over and through which their fronds are laced and twisted, draping their supporters with an exquisite mantle of bright green. In cultivation I have found *Lygodium* thrive well potted in two parts peat, two parts loam, and one part leaf mould and sand together. In potting, great care must be taken to prevent any accident happening to the drainage. Most of the species enjoy stove heat, and require a liberal supply of water, although some kinds will grow in a greenhouse temperature. A custom prevails with some Fern growers of cutting off the fronds of *Lygodium* quite level with the pot every spring; this, many say, makes them grow stronger, but nothing can be more directly in opposition to all natural laws, and I firmly believe it is only an excuse for hiding carelessness in the shape of scale-infested fronds; depend upon it the best plan is to remove pinnæ or fronds only when they become unsightly, and if ordinary care be taken in cultivation this necessity will not occur frequently.

L. japonicum.—The fronds of this species grow to a considerable length, and that very rapidly. When trained up and round the pillars of a Fern house, or indeed an ordinary stove, it produces a most beautiful effect, and it succeeds equally well trained along a rafter, or when used to form a screen for covering a wall; in either of these positions this plant is able to develop its beauties and display its true character, which is not the case when it is grown upon small trellises. Another use to which the fronds of this species are admirably adapted is for twining

round the stems of epergnes for the decoration of dinner-tables, &c., and I think I may safely venture to say that for this purpose it would be extremely difficult to find its equal for elegance and simplicity. The fronds of *L. japonicum* are branched, and the pinnæ are palmately lobed, whilst upon the apex of each lobe is situated a little spike of dark brown sori, which contrast beautifully with the bright green of the frond. This species will thrive in a comparatively cool temperature, and it seems to be extremely common throughout China and Japan.

L. flexuosum.—The fronds of this kind are much larger than those of the previously-described plant; indeed it is one of the largest species in the genus, the pinnæ are opposite, narrow, twice-forked, and frequently measure 12 inches in length, whilst the fronds attain a great length under genial treatment. As in all this genus, the sori of this kind are exerted, and form a rich brown marginal border to the deep shining green of the pinnæ. It requires a stove temperature, and may be used with advantage in all the situations recommended for *L. japonicum*, saving the dinner-table stands, and from this its size excludes it; on account of its size, also, it requires a greater space to ramble over. It is sometimes called *L. dichotomum*, from the peculiar branching of its pinnæ, and is widely distributed throughout the islands in the Indian Archipelago.

L. palmatum.—This species is not a large grower, and is only sub-scandent, and perhaps should not have been classed with these. I have used it, however, to hang down from a pocket in the cool fernery with great success; the somewhat broad præmorse barren pinnæ, and the curious contracted finger-like fertile ones, presenting a unique appearance, and the sight of this plant well grown in such a position never fails to arrest the attention of Fern lovers. It is a deciduous plant, a native of North America.

L. scandens.—This kind resembles *L. japonicum* very much in some of its stages of growth, and, indeed, by some authorities they are considered identical. This may be the case, but yet when the two extreme forms are in a collection they certainly deserve distinct names. The form now under consideration is equally beautiful with that already described under the name of *L. japonicum*, indeed it is even more finely divided; the fronds extend indefinitely; the pinnæ are palmately lobed and of a beautiful bright green in colour, the fertile ones clothed at the margins with light brown sori. For covering a rafter or pillar in the stove it is admirable. Native of the East Indies.

L. polystachyum.—A noble large-growing species, producing large fronds with pinnæ from 6 to 12 inches in length, or even more, the stems clothed with a short white tomentum; pinnules obtuse, 3 or 4 inches long and 1 broad, deeply lobed, each lobe being much contracted towards the apex, and upon the under side of these contracted parts the dark brown sori are produced, and not exerted as is usual in this genus. A highly desirable plant, not sufficiently known or grown by lovers of Ferns. Native of the Indian Archipelago.

L. microphyllum.—This is a superb plant, but the form which I have grown seems to be extremely rare in cultivation. It produces elegant bright green barren pinnæ, whilst

the fruiting pinnae are reduced to little brown fruiting lobes, which contrast beautifully with the bright green. For a pillar this species is an especial favourite of mine, and it would be one with every Fern-grower if it were better known. This form is a native of the Philippine Islands.

LYGODICTYON.

In their general habit and appearance the plants composing this genus are exactly similar to the Lygodium, and they are distinguished from them only by having reticulated veins. This, however, amongst an order of plants in which the venation is of far greater importance than in any other order, is a good and abiding character. The soil and treatment should be the same as for Lygodium.

L. FORSTERI is a very handsome scandent plant, producing bipinnate fronds, which are several times forked in a dichotomous manner; the pinnae are oblong-obtuse, the sterile ones longer than the fertile, but the latter are much the broader; the sori are dark brown, dense, and exerted as in Lygodium, thus rendering it a most attractive plant for rafters or pillars in the fernery. It thrives well in the stove, but it will also attain considerable proportions in a cool house. Native of the Polynesian Islands.

GYMNOG MM

A genus very popular, and known to most plant lovers by the names of Gold and Silver Ferns, about which I hope to say a few words in a future article. The species to which, however, I wish to draw attention in this place is a climbing plant, and well merits the attention of Fern-growers. It requires a stove temperature, and should be potted in peat and sand only.

G. FLEXUOSA.—This most elegant plant produces fronds of an indefinite length. The rachis is zigzag, and the pinnae are bi-tripinnate and refracted; pinnules narrow and somewhat wedge-shaped; it is entirely destitute of the farinose powder so common to the genus, and dark green in colour. It climbs over bushes and shrubs in its native habitats, and its light graceful fronds produce a charming effect. Native of South America.

PLATYLOMA.

This genus contains several very handsome species; only one, however, can be introduced here as a climber, and it should find a place in every collection of Ferns on account of its extreme beauty, its distinctness, and because it succeeds well in a cool house. This genus is characterised by its forked veins, and by the sporangiferous receptacles being terminal and oblong; these, being contiguous, form a broad unbroken marginal sorus; the indusium is linear, continuous, and very narrow. Rough fibrous peat and sand, with a little light loam, suit this genus admirably.

P. FLEXUOSA.—This is sometimes to be met with under the name of *Allosora flexuosus* and *Pteris flexuosa*; it is a most elegant plant, and produces a fine effect trained upon a rafter or pillar. The fronds are 6 or 7 feet in length, tripinnate, with a zigzag stem; the pinnules are small, ovate, and light green in colour; the sori form a continuous marginal band on the under side, greatly enhancing its beauty. As before remarked, it thrives well in a cool house, and is a native of various parts of South America.

ADIANTUM.

Under the name of Maiden-hair Ferns the genus *Adiantum* is familiar to all lovers of plants. All the species are handsome, and some of them rank amongst the most beautiful Ferns in cultivation. The fronds vary from simple to pinnate and bi-tripinnate, with jointed pinnae, which have an excentric costa or midrib; the veins are forked and free; the sori marginal, and covered by a conspicuous indusium. Only one scandent species has up to the present time been introduced in a living state to our gardens, although other handsome climbing kinds are known to exist in tropical countries. It should be potted in peat and light loam.

A. FLEXI is a distinct form of Maiden-hair, and cannot be mistaken for, or confounded with any other species. It is known in some collections by the name of *A. flexuosum*. Its fronds extend to a considerable length; they are tripinnate, having the rachis and petioles covered with a reddish-brown pubescence; the pinnae are sub-rotund, and dull green in colour. It forms an elegant plant either for pillars or rafters in the stove fernery. Native of Mexico.—*EXPERTO CREDE*.

IPECACUANHA CULTURE.—According to *Nature*, there is good report of the progress of *Ipecacuanha* cultivation in India, where it is found so valuable in that prevalent disease, dysen-

tery. Since Dr. John Murray obtained for it the notice of the Indian Government, it has been successfully planted in the Neilgherries and other of our hill settlements, and in the plains. It has done well even at Calcutta.

NUTRITION AND SEX IN PLANTS.

(Read before the American Association for the Advancement of Science.)

In my paper on the laws of sex in plants, which I read to the Association last year, I gave some account of a few of the leading facts I had observed, which seemed to indicate that a higher degree of vigour or vital force was necessary to produce the female than the male sex in plants. I have not met with one fact which has suggested any other conclusion; nor have I heard any fact suggested by others which could lead to any other opinion. Wherever there has been any change in the sexual relations, the male flowers or organs are invariably associated with declining vigour, while only in those parts of plants most favourable to the highest state of vitality are the female flowers most numerous or generally found.

This theory is so capable of easy demonstration by anyone who will personally examine the first monoecious tree or plant he meets, that I feel sure nothing further will be needed from me to sustain it. I propose now to go a step further, in the endeavour to ascertain the exact laws of nutrition, by which we may control these sex-producing forces respectively.

I have here some specimens of *Castanea americana*, our common Sweet Chestnut, as my first contribution to this class of facts.

But first I would call attention to the fact that there are two classes of male flowers in this tree. It is scarcely possible that this should have escaped the eye of other observers, but I find no reference to it in botanical works. One class of male flowers comes out from the axils on half-starved shoots, the other class terminates the strong vigorous shoots which bear the female blossoms. Those of the former class have their flowers set densely on the rachis—on the latter they are somewhat scattered, and do not open until a week or ten days after the latter. The numerous flowers we see on the Chestnut trees are of the former class, and generally have mostly fallen before those associated with the female flowers open. I think it likely that one of these classes does not perform the usual fertilising functions, but could not satisfy myself positively. The interest for us here is to note the antagonism, so to say, between the male and female blossoms. The comparatively weak spikes show that they were formed only after the female flowers had received matter enough for their perfect development. Only the surplus matter goes to form the male flowers at the apex. This is better shown by the fact that often there is no prolongation beyond the female flowers—no male blossoms; at other times only a few—never, as we have seen, the number which appears on those spikes which are wholly masculine in their nature.

In regard to the influence of nutrition on sex, another specimen I exhibit is from a tree at least 40 feet high and 6 in circumference. It is on my ground, stands out by itself, and has borne fruit regularly and in good crops annually. This year the leaves are all streaked with yellow, as in this specimen.

Horticiculturists well know that this appearance on the leaves of plants arises from an interruption of the nutritive functions. If a branch be partially ringed to induce fruitfulness, or if the roots be injured in transplanting, or rotted by an over-supply of water, a yellow tint to the foliage is the invariable consequence. In some way, then, this Chestnut tree has this season met with some check to its nutritive system,—received a blow to its vitality, which has resulted in this yellow-tinted leaf. The effect of this on the sex is, that though thousands of male flowers are produced, there is not one female flower, one young chestnut, on the whole tree that I can find.

I think this instance satisfactory as far as it goes, that defective nutrition is one of the agents which operate on those laws of vitality that govern the sexes.—*THOMAS MEEHAN.*—(*American Gardener's Monthly.*)

GARIBALDI STRAWBERRY.

I OBSERVE in your issue of the 8th inst. that a correspondent says the Garibaldi Strawberry which I raised has been proved to be *Vicomtesse Héricart de Thury*, and that the latter has been sent out under the name of Garibaldi as a new Strawberry. I beg to deny any such assertion, and further beg to state that when the *Vicomtesse* is grown along with the *true* Garibaldi it will be found that my Strawberry is much superior

in many respects. Your correspondent further asserts that Garibaldi was sent out last year; allow me to inform him that I sent it out five years ago. If he will write me on the subject I shall give him sufficient references. I have only to add that at present Garibaldi stands unrivalled.—T. ARMSTRONG, *Belah Gardens, Stanweir, Carlisle.*

THE SLOUGH CARNATIONS AND PICOTEEES.

Now that florists' flowers are once more looking up, and we are, I hope, likely to see more of them in the metropolis than we have done during the past few years, I shall be justified in drawing attention to some of them as they come under one's notice; and having had an opportunity of seeing Mr. Turner's collection of Carnations and Picotees in full bloom, an account of what I saw cannot fail to be of interest to some.

It was on my return journey from Okeford Fitzpaine and Salisbury that I found myself at Reading and enjoying the hospitality of some kind friends there, who much wanted me to go with them the next day to the Oxford Show. The weather was insufferably hot, and I heard so poor an account of the show and the difficulty of getting about, that I would not go. Instead, I determined to visit the classic grounds of Slough, one of the choice spots of "merrie England" to the florist, for has not there the very prince of florists set an example to all lovers of flowers as to what can be done? From thence he has brought forth artillery that has ranked the finest competitors. In Azaleas, Pelargoniums, Roses, Auriculas, Dahlias, Pinks, Carnations, and Picotees he has shown himself a very giant; and for neatness, order, and well-kept grounds it would be difficult anywhere to find the equal of Slough. I knew that the best twenty-four Picotees and Carnations had gone off to Oxford, but knowing how extensive his stock was I felt sure this would make no very perceptible difference: nor was I wrong. Independently of the large stock in pots out of doors, a lean-to in a northern aspect was filled with a splendid collection in fine health and full bloom. Ball, the intelligent and able cultivator of these and the Auriculas, was at home, we had a good hour's chat over our favourites, and I here give the result of my observations, seconded by his greater experience.

In PICOTEEES I would place at the very head of the list, as possessing the finest qualities, a flower sent out by Mr. Turner last year—Admiration. It is a heavy-edged purple Picotee, of splendid habit and first-rate properties. Wherever it was in the house it was at once recognised by its fine habit and appearance. It is some satisfaction to know that this, one of our newest flowers, is also our very best. Miss Turner is another very beautiful flower of a different character, a light-edged red, with a very pure white ground and a medium edge of bright red. These, with Charmer, medium purple edge, very constant and distinct; Colonel Clerk, heavy red, with broad smooth petal, large, full, and regular; Mrs. Fisher, a light-edged rose, fine and full, good ground, and beautifully marked; and Nimrod, a rich dark purple, were among the newer flowers that struck me as being fine.

Amongst older flowers, in heavy-edged red kinds Exhibitor, Favourite, Mrs. Dodwell, Mrs. Norman, and William Summers may be set down as excellent; while in light-edged red Agnes, Miss Holbeck, Mrs. Kelk, and Penelope are equally good. In heavy purple-edged, Lord Nelson, Prince Arthur, Duke of Devonshire; and in light purple-edged, Amy Kobsart, Bridesmaid, Mary (a very beautiful flower), and Lady Elcho are flowers of first-rate excellence. No class is a greater favourite with me than the rose and scarlet-edged Picotees, and Mr. Turner's collection was especially rich in them. Miss Meeking, Queen Victoria, Princess Royal, Rosalind, and Unexpected are very fine; while amongst light-edged varieties Lucy, Miss Sewell, Miss Paxley, and Rosy Circle are exceedingly beautiful. I have in these marked only those which seemed to be not only beautiful but good growers; for in all flowers, no matter what they may be—Roses, Auriculas, Carnations, or Picotees—unless we have good constitution beauty is of little moment. They only tantalise us by their beauty which we enjoy but for a little while ere it perishes.

Amongst the recently raised CARNATIONS the following may be regarded as valuable varieties:—Annihilator, a good scarlet flake, good white ground and bright marking; Eccentric Jack, large and well-marked crimson bizarre, good shape with broad petals; James Merryweather, rose flake, a fine variety, good habit; Rifleman, crimson bizarre, very large bold flower, will be probably a great favourite in the north; William Cowper, a fine flower, scarlet flake, and very constant; and Graceless

Tom, a fine full-sized crimson bizarre, well-marked and constant. Amongst scarlet bizarres of older date the following were good:—Flambean, Lord Raneliffe, William Pitt, and Brutus. Of crimson bizarres, Jenny Lind, Paul Pry, Queen Victoria, and Lord Milton are fine varieties. Probably the best of the purple flakes were Ascendant, Earl Stamford, Mayor of Oldham, and Mayor of Nottingham. In scarlet flakes Christopher Sly, Justice Shallow, Lydia, and Illuminator are good; and in that charming class rose flakes Flora's Garland (a difficult flower to grow), Lady Ely, Princess Royal, Rose of Castile, and Samuel Moreton are very fine.

In mentioning these I have only selected a very small portion of what I saw, as they seemed to me to be amongst the finest; but in so extensive and varied a selection there was such an *embarras de richesses* that one was fairly confounded by it. Let those who may think of growing them put themselves into the hands of an experienced grower like Mr. Turner, and they will not fail to make a good start.—D., *Deal.*

PEACHES AND NECTARINES.

DR. HOOGE'S "Fruit Manual" is a very useful book. It, by giving the synonymes, and describing the shapes of the fruits, the forms of the stones, and the size of the flowers and the glands, has enabled me to find out deceptions, and to determine the varieties of misnamed Peaches and Nectarines. I hope we shall soon have another edition, describing the latest seedlings, and also distinguishing the colours of fruits grown under glass from those grown out of doors, as they are very different. By the help of this excellent work I found out that I had the Grosse Mignonne under three synonymes—namely, Royal Kensington, Padley's Early Purple, and Smooth-leaved Royal George. These four synonymes, of course, quadruple the chances of sale; but the act is dishonest. I advise purchasers of the above fruit trees to try the sorts sent out by means of the flowers, the glands, the shape of the fruit, and the serration of the leaves. A powerful glass is necessary to examine the glands, which are either kidney-shaped or round. The glands are sometimes so small that the unassisted eye cannot always determine their shape. It is said that glandless leaves are subject to mildew; under glass it may be so, but I never saw mildew on the leaves of my Peaches and Nectarines out of doors.

As soon as the Peach and Nectarine season is over, I think of referring to the fruits, especially to those of later origin. In the meantime I express my gratitude for such a magnificent crop of fine fruits. I have cut in half the leaves of all the trees that have done fruiting. It is a good plan, practised here successfully for two years, as it enables the sun and air to mature the wood of the current year, upon the ripening of which future success greatly depends. The skin should be blood red, and not of a pale sickly green.—W. F. RADCLIFFE.

THE ROYAL HORTICULTURAL SOCIETY'S HYACINTH SHOW.

I SHOULD very much like to call the attention of the Council of the Royal Horticultural Society to two points in connection with the show of Hyacinths, &c., annually held by the Society.

Firstly, the low value of prizes offered, and, consequently, the little encouragement given to the flowering of these bulbs. I believe the number of exhibitors at this Show decreases year by year, and I think the principal reason is because the prizes offered are not of sufficient value. I have been a successful exhibitor of Dutch bulbs for three years, and I can confidently state I have barely covered my expenses. I do not mean to say I want to make a profit of these exhibitions, but I do mean to say that if more adequate prizes were offered more persons would be induced to enter the field, and the Society would benefit by the results. I certainly am of opinion that the growth of these spring flowers cannot be too much encouraged, coming, as they do, at a time when the first days of warmth occur, and when flowers are so highly prized.

Secondly, I think if the Committee were to issue a spring schedule distinct from the summer one, and at an earlier date than usual, both the Society and exhibitors would derive a great benefit. Dutch bulbs are not like plants which a man has in his possession, it is necessary to procure fresh ones every year, and the growers recommend an early purchase; but how is an intending exhibitor to know what to purchase if

he does not know what he has to exhibit? I should like also to see more classes open to amateurs.

I have made these remarks as one who takes an interest in the welfare of the Society, and I hope the Council will receive them as such.—AMATEUR.

CAPEL MANOR, HORSEMONDEN, KENT.

CAPEL MANOR is a commodious edifice in what is called the Lombardic style of architecture, situated midway on the slope of a gentle eminence facing the east, in the picturesque parish of Horsemonden, five or six miles from the Paddock Wood Station, on the South-Eastern Railway. The surrounding country presents a series of undulations, all available for tillage, but sufficiently elevated to afford commanding sites for dwellings without bleakness, being well wooded, and for miles having a clothed appearance. Perhaps nowhere are Hops and fruit trees more industriously attended to, and with more successful results. The gentle hills and smiling valleys teem with vegetable life, exposed to no smoke from factory chimneys; for although report says the iron of the railing round St. Paul's Cathedral was smelted in an adjoining parish, the furnaces that supplied it have long since passed away, and so has the manufactory of woollen cloth, for which the village of Horsemonden was at one time famous. The cultivation of the ground has been all the more actively engaged in, the nature of the soil and the undulating character of the country being favourable. The district contrasts strongly with the level tract of land to the north of it, forming what is called the Weald of Kent; the high ground of the parishes of Horsemonden, Goudhurst, Cranbrook, and Frittenden overlooking this flat on the one side, as the high ridge of hills forming the Coxheath range does on the other; and it is partly owing to this cause that from the tower of Goudhurst church, although the village is situated at no great elevation, it is said fifty-two other churches may be seen, and possibly no village within this range of view contains five hundred inhabitants.

Only eleven years ago the site of the mansion and grounds was a wood and meadow, but so well adapted is the soil to the growth of shrubs and trees, and so carefully have they been planted and tended, that the place presents a clothed appearance already. One circumstance, no doubt, contributed to this result—there were plenty of large Oak and other trees about the mansion and its surroundings, as well as in the park, so that these essential features were already provided, for although the place is quite new, it is very near the site of a very old residence that used to be the home of the ancestors of the present proprietor. —Austen, Esq. With laudable consideration the park and adjacent fields had never been denuded of their timber, as so many estates were about the beginning of the present century, when oak commanded so high a price, consequently the park is amply, nay, profusely, furnished with trees of all sizes.

The mansion is built of a light coloured sandstone found in the neighbourhood, with stone of another sort for dressings, and its cleanliness contrasts well with the healthy herbage by which it is surrounded. The carriage front faces the north-east, while the south-eastern and south-western sides are garden fronts, the offices being on the other side. Situated on a declivity facing the south-east a terrace runs along that side with an enriched architectural retaining wall and parapet, while below is a large basin of water, with some beds edged with stone on a spacious gravelled area, contrasting strongly with the cramped arrangements of some gardens of a like kind, where the design would seem to be to get as much as possible into the smallest space. Suitable flights of steps lead down from the upper terrace, while below, the dressed grounds extend some distance as shrubbery, intersected by walks conforming to the inclination of the ground. A summer-house forms a termination to one of the walks in this quarter. On the south-west side the ground is more on a level with the base of the mansion, and a flower garden on turf is suitably placed there, as well as a very neat conservatory upwards of 70 feet long by about 28 feet wide. This adjoins the mansion, and is well clothed with climbers in robust health; amongst them I noticed a fine plant of *Lapageria rosea* blooming profusely. *Passiflora Buonapartea* was in excellent health, and was said to have bloomed well, while a *Thibaudia* growing against one of the ends of the building presented several clusters of its tubular flowers in great profusion. The shelves and central beds were well filled with healthy flowering and fine-foliaged plants, and presented a gay and interesting appearance, meeting the

climbers from the roof, and showing a high state of cultivation. Encaustic tiles formed the pathway, which had a stone kerb, and the workmanship of the whole building was of the best description. I believe Mr. Ormson erected it, as well as the other forcing houses which will be described hereafter.

The dressed grounds are very extensive, and differ from those at many places of a like kind, the walks being in most instances straight and pointing to some object either placed there to form a suitable terminus, or directed to some feature in the distance. The picturesque village of Goudhurst, about two miles off, was brought into view, while a summer-house formed a suitable termination at another place. Most of the walks diverging from the principal ones were also at right angles, thereby dividing the ground into a series of squares and parallelograms, one of which had been devoted to that which has now become an important appendage to most country houses, a croquet ground. Beds of Tea and other Roses in excellent health, with abundance of flowers even at the time of my visit (the end of August), were also met with at various turnings, while the choicest Pinuses had suitable positions, and some steep banks and other inequalities were well clothed with shrubs of various kinds, amongst which I noticed *Escallonia macrantha* luxuriating almost as well as a *Laurus tinus*, while trained against the mansion *Magnolia grandiflora* was flowering. On a prepared border near the conservatory a large bed, or rather bank, of the best varieties of *Rhododendrons* must present a gorgeous sight when in bloom. These shrubs, it must be observed, were here and there backed by good old Oak or other trees, and the rear of the mansion was well sheltered by trees on still higher ground, giving the whole an appearance of snugness.

The kitchen garden and forcing houses also lay in this direction. The garden proper is surrounded by good walls well covered with fruit trees bearing luxuriant crops. The Peaches, Nectarines, and Plums could not well be excelled, and the same may be said of some Morello Cherries on a north wall. Accompanying the latter was a late table Cherry, which Mr. Seale, the gardener, said he believed was a Late Duke Cherry of some kind. Outside the garden was more than the ordinary amount of slip, for the space far exceeded that enclosed by the walls, and was devoted to the growth of hardy fruits and common vegetables. Very heavy crops of Plums, Pears, and Apples on standard trees eight or nine years old, proved how well the situation and treatment suited them.

In the hothouses heavy crops of most excellent Grapes were grown; the varieties were Black Hamburgs, Muscat Hamburgs, and White Muscats, remarkably fine for size of berry. The stems of the Vines showed a sturdiness of growth rarely met with in plants so young, while the foliage was not at all large, confirming what I have before advanced, that size of leaf alone is not the criterion of the Vine's doing well. The fruit from the early house had been mostly gathered, but an abundant crop was coming on in a later house. A Fig-house had also yielded well, and the trees were showing a second crop. The walls were everywhere closely covered with healthy fruitful trees, and the interior of the garden showed, by the abundant crops of vegetables, that the soil and its management had been such as to successfully combat the very dry season. Even Peas were in bearing, although much attacked by birds, which threatened to destroy that crop.

As the natural character of the soil has always much to do with the well-being of every crop, the worthy proprietor of Capel Manor and his energetic gardener have been fortunate in this respect; but the soil is one not easily described, unless the equivocal term of a stiff sand be applicable, for it was of that character—a light coloured material free from stones, but not so porous that water would not stand upon it when it was kneaded together. Underneath was the sandstone of which the mansion and other buildings were constructed. This soil, I feel convinced from what I saw, is more conducive to the well-doing of the Vine than so much lime rubbish as is advocated by many, and although pale coloured I believe it contains iron, for at a short distance from the garden the bed of a little streamlet exhibited a bright red incrustation. The soil of the kitchen garden, as well as of most parts of the pleasure grounds, was also of good depth. The latter, however, had mostly been disturbed, so that the original surface was only to be guessed at; however, I may state that *Rhododendrons* seemed to thrive tolerably well in it, although not so well as in some borders made for them by an admixture of bog peat from a swamp in the park. This class of soil pervades much of the district to the eastward of Tonbridge Wells, as well as around

that fashionable town; it is a soil that must not be meddled with when it is wet, but when properly tilled, and the season is favourable, it works like velvet, as a farmer friend observed, its texture being so fine. Most trees seemed to thrive well in such a soil, as well as many vegetables; perhaps the Cabbage tribe required more lime.

I cannot draw this communication to a close without mentioning that the Apricot was succeeding better than it does in most places, for it is often in an unsatisfactory condition; here the trees were healthy, well-formed, and fruitful. It may be said they are young, only nine or ten years old at most; but Mr. Seale took me to look at a couple of old trees growing against a house, which two centuries or more ago was the dwelling of his employer's ancestors. This residence stands on the edge of the park, in lower ground than the present mansion, and is one of those timber-framed buildings with the upper storey overhanging the lower one, which are now less frequently met with than formerly, though they have not entirely vanished from our old towns. Against this residence were two Apricot trees that might almost equal it in antiquity; they were standards, or what are sometimes called riders, with stems showing but few symptoms of decay, certainly nothing of the shell-like character which such trees often present even when the top is healthy. The circumference of one was 45 inches, and that of the other 38 inches at the smallest part of the 5 or 6 feet which formed the bole. Mr. Seale thought they were of the Breda variety, and that their age was from 150 to 200 years. The soil, although partaking in some respects of that of the rest of the garden, was much less inviting at the spot where the trees were growing; nevertheless, there they were, showing that in a suitable soil the Apricot is a much longer-lived tree than it is often supposed to be. The tops, though showing signs of great age, and no doubt affected by a drain having been cut near, still possessed sufficient health to warrant the belief that they would outlive another generation, and the fruit was said to be as good and as plentiful as from younger trees of the same variety. Some other old trees and shrubs surrounded this ancient abode. The Yews were not at all satisfactory, but some old Box trees had attained unusual dimensions, showing that although certain soils and situations will grow almost anything, there are, nevertheless, species which thrive better than others in particular soils.

I have, in conclusion, to thank Mr. Seale for his courtesy in pointing out the various features connected with this fine place, and hope both he and his employer will long enjoy the grounds they may be said to have created, and which they have furnished in so short a time.—J. ROBSON.

STOCK SPREADING TO THE SCION OF A PLUM TREE.

I saw recently at Yatton Keynell Rectory, Wilts, a Plum tree nailed to a wall. It had made to my mind a remarkable sport. The tree was grafted low, as usual, and immediately above the graft it branched out, covering a good space of wall. From one limb there had issued, about 4 feet from the ground, a branch of the pure wild stock, while below it was a branch on the opposite side bearing the proper fruit, and just above another piece also bearing the same. Is this kind of growth very uncommon, and what can be the cause?

A friend's Laburnum tree has made a sport which bears purple flowers. Will the seed from those flowers, produce plants bearing purple flowers?—A. H.

[Most probably not. The influence exerted by the stock over the scion is subject to many anomalies, and they, as well as sports in the colours and forms of flowers, are among the unexplained facts of the vegetable kingdom.—Eds.]

STOCKS FOR APPLE GRAFTS.

CAN some of your arboricultural or pomological genealogists favour us with the pedigree of the Apple stocks called *English Paradise, French Paradise, Pommier de Paradis, †Doucein, Burr Knot, and Sühhert, and describe any characteristic peculiarities of growth, and hue of bark and foliage? We have heard many wonderful tales of dwarfing stocks such as are named and of precocious crops from such stocks, and it would be as interesting to learn how nearly allied to the Crab or Apple these some-

what alien stocks are, and how far the produce is that of hybrid or pure Apple culture.

I am but an amateur, though I will venture to say that the Crab alone is the stock for fruit true to itself in colour, flavour, and size alike. The genus of the stock and the scion, whatever variety of Apple is grafted, is the same: hence the truth of the produce. And dwarf Crab stocks are, I think, drawn from Crab seedlings constitutionally so, the stouter seedlings going for standard trees; at least I have dwarf Crab stocks robust, round, and dwarfed, and pyramidal, in my ground. But though the Crab is my choice, the history of the Paradise, and other stocks would present to your readers the choice of stocks in use by our nurserymen. And can we be told to what extent the Apple stock from Apple seedlings—the cultivated Apple, not the Crab or wild Apple stock—is used, and its results?—READER.

HORTICULTURE AMONG THE MORMONS.

ON our tour to California we spent a few days very pleasantly at Salt Lake City. The houses of the inhabitants are embowered among hundreds of choice shade trees along all the public streets, while the gardens are full of fruit trees of great health and luxuriance. We could hardly believe that, only a month beforehand, a plague of grasshoppers had descended from the mountains and cleared the gardens and trees of every living leaf, and now all was bright and cheerful again. The trees were loaded with fruit, and Apples, Pears, Plums, Apricots, and Cherries were hanging with ripe specimens from nearly every tree. It is curious to see the Apples hug the branches and stem, as closely as if fitted for their place, while with us every fruit hangs from a twig or dangles from the end of a limb. The climate is exceedingly favourable, frosts rarely occurring after vegetation has really started in the early spring. The days are always pleasant, rarely very warm; the nights always cool, with agreeable breezes; and the abundance of water for irrigating purposes favours the growth of almost every species of fruit. Elder Smith showed me a row of Apricot trees, planted eight years ago from seed obtained from the Department of Agriculture at Washington. They had been fruiting four years, were an average of 15 feet high, and proved to be of four different kinds. The specimens we saw, left from the attacks of the grasshoppers, were as large as a good-sized Peach, and fair quality, but not as delicate in flavour as our own varieties of the Atlantic States. The Peach trees have more compact heads, less spreading, leaves are of a deeper green, leading shoots do not grow quite as long. We have more side shoots than they, but the entire top of their trees is a mass of dense leaves. No cures, borers, or insects of any description are known. The yellows have never been seen, and apparently there is no natural enemy. The Apple tree bears in two years from cuttings or grafts, and fruit is beautifully coloured. Several specimens of Red Astrachan and Sweet Bough Apples attracted my special attention; the latter for its size, being 12 inches in circumference; the former for its deep bloom, which, when brushed off, revealed a brilliant red-coloured surface, equal to the tints of the rainbow, or the finest sun painting on the clouds of a sunset sky. We have nothing to equal it. Undoubtedly the dryness of the climate, and the soil composed of the washings of the mountains, helped materially in the rich colouring of the fruit. All the soil is full of mineral matter, and this exerts its natural effect in high colour.

The best garden of the place is that of Mr. William Jennings, the richest man of the entire territory, and a successful merchant, who favoured us with conveniences for a visit to his garden. His home grounds occupy about five acres, devoted almost entirely to fruit. A lovely lawn in front of his house, with its deep velvety green carpet, was skirted with rows of flowers, Fuchsias, Dahlias, Roses, Geraniums, and Lilies. From the balcony windows of the parlours we catch an exquisite view of the snow-capped mountains of the distant ranges.

The city is surrounded in all directions with lofty peaks, varying from ten to fifty miles distant; and many with snow-topped summits, glittering bright and brilliant against the deep blue sky.

Cherries are a favourite crop with the proprietor, several varieties being planted, of which the Napoleon Bigarraan is most favoured. The flavour is more rich and exquisite than with us, but it is not so finely coloured. With the other kinds the family enjoy Cherries for a season of six weeks.

Peaches were thriving admirably. In fruiting time they have gathered specimens fully 13 inches in circumference.

* Query, if dwarfed Crab stock.

† Query, if French Paradise stock.

Strawberries are abundant, and throughout the entire bed will average 4 inches in circumference. The Wilson and Longworth Prolific are the best. Agriculturist, Jucunda, and a dozen others imported from the Atlantic States, have proved a failure.

Grapes are successful beyond measure. The Black Hamburgh, which we in the east must grow under glass, here is free and luxuriant in the open air; as also are the Chasselas, Sweetwater, White Frontignan, &c. Bunches of the Sweetwater have often been picked as big as a man's hat, and weighing over 10 lbs. Gooseberries are large and sweet, almost of the size of Crab Apples.

The Delaware, Uniou Village, Catawba and a few other eastern Vines, are grown with success; and yet are mere pigmies by the side of the noble Hamburgh and Chasselas. Apricots, Almonds, Mulberries are everywhere successful, while Currants are luxuriant to a fault.

Asparagus is fully equal to some of the specimens of our famous Conover Colossal. Of Plums, the Green Gage and Magnum Bonum are much the finest, still not very productive. Potato beds had suffered greatly from the "hoppers;" the leaves had been stripped and the tubers become watery. Still, very fine specimens of the Early Rose were dug, and pronounced of superior flavour by Mr. Jennings. The Ash-leaved Kidney is also successful, being perhaps the finest flavoured of all he had tried. The White Ash-leaved is nearly equal to the Early Rose. Mulberry trees are very thrifty. The people are now engaging in their culture for raising silk. The growth is very rapid, usually 4 feet a-year, but Mr. Jennings mentions several instances of 11 feet a-year from cuttings. The Sweet Almond is at home by the side of the Plum and Peach, bearing fruit.

Mr. Jennings has some very fine Vines of the Mission Grape, so universal in California. They bear large loose clusters, have short but very thick-jointed shoots, some of the joints being nearly an inch in diameter. The fruit is fine for table, and universally made into wine. The Buckland Sweetwater Grape grows with perfect vigour, and produces bunches large enough to fill a hat.

The Muscatel is also adapted to the climate. Specimens were shown us of an Improved Rocky Mountain Currant; berries as big as Cherries, and 2½ inches in circumference. The bush is large, fully 6 feet broad, and above 4 feet high; colour of fruit deep black; flavour sweet for a Black Currant, but best fitted for preserves. On the posts near the entrance to the house were specimens of the Mexican Cacti thriving in the open air. What a singular sight to behold—on the one side Apples from the east, Grapes from the west, tropical plants from the south, the Almond from Europe, flowers from the Atlantic States, lawn Grass from England, while over-topped by all are the unchanging mountains, always girt with snow, and picturesque in their contrast with the verdure beneath!

Mr. Jennings's place is an exception to the general character of the gardens of the inhabitants. Some are very neat, but usually the gardens of the Mormons are not well kept; perhaps the devastation of the hoppers has taken away their enthusiasm, for we saw an abundance of weeds in many gardens, and not a soul working therein.

Evidently everything is left to climate and water, and only at occasional long intervals the gardener appears and cleans out the weeds.

The soil is dry and gravelly. It would naturally be poor and worthless, but the long streams of water come rolling down, and behold the leaves grow of a deeper green, and their life is renewed again and again.—(*American Horticulturist*.)

WAYSIDE JOTTINGS.—No. 6.

Just before reaching the summit of the "hawse," an amusing incident occurred. The Doctor had diverged from the track to the right with the view of reaching the summit of Cockup, which overhung our path in that direction, by making a detour which would lessen the difficulty of the ascent. About a hundred yards farther on, the Squire and I decided upon making a similar attempt where the path to the top was considerably more abrupt and precipitous than that adopted by our comrade. We were induced to take this step by a desire to examine some tufts of vegetation which we saw springing from the crevices of the rock overhead, and which we could not identify at our present distance. The Doctor had by this time disappeared from our view, though his shrill whistle could occasionally be heard reverberated from the crags around and above us. Just

as we were about to encounter the only remaining obstacle to our safe ascent, the Squire suddenly declined to pursue the attempt further, affirming that his head was becoming affected with premonitory symptoms of vertigo. Reaching the head of my staff towards him, I exhorted him to persevere, but my eloquence was tried in vain. "I have no desire needlessly to imperil my limbs; and recollect," added he humorously, pointing to the game bag slung from his shoulder, "the claret bottle is here. Supposing any mischance should happen to the wine flask." I replied, directing his attention at the same time to a limpid stream far below, which was leaping from rock to rock, and glistening in the sunshine like a silver thread, "We might be worse off. Remember the rapturous words of the Roman poet—

"Dulcis aquæ saliente rivo restinguere sitim."

"That's all very fine," was the rejoinder, "but let us get down." Just at this point we were startled by a rumbling noise among the rocks above us, towards which we quickly turned our eyes, half expecting to see our medical friend making a somersault over the edge of the precipice which separated him from us. A moment's suspense revealed to us the cause of the noise, as the Squire's favourite pointer, Nino, unable to stop the momentum of her downward career, sprang from the ledge and alighted with a thud upon her master's bill-cock. This probably saved the poor animal from serious injury, as it served to break the force with which she finally landed among the scree below. As it was, she limped with pain for the rest of the day. Being shortly rejoined by our friend, we began to descend the opposite side of the pass, until we arrived at a small and rudely-formed sheepfold, close to the brook above referred to. Here a halt was called, and the sandwich case and wine flask being produced, their contents were discussed to our very great comfort and satisfaction. A more appropriate place for the purpose of a mountain luncheon could hardly be imagined. The sward of the diminutive fold was of the most vivid green, and cropped as no lawn mower, Archimedean or Siens Messor, could accomplish the task. Blocks of the schistose rock, the staple of Cockup, formed the boundary of the inclosure, among which, at every available opening, the beautifully curled leaves of the Parsley Fern or Rock Brakes sprang forth in every imaginable variety of form. In the brook close to our feet little fishes played, one of which, a sprightly burn trout, was momentarily made a prisoner for our examination, and having been submitted to a close scrutiny, was returned to his native element, evidently none the worse for his vigorous bounding on the green turf. Several hundred feet above our present level, on the broad shoulders of one of Cockup's bigger brothers, named Calvo, a large flock of rocks were enjoying themselves, busy scanning the turf for the grubs or larvae of the Tipula, which often abound on elevated moors.—II.

THE BOTANICAL DEPARTMENT OF THE BRITISH MUSEUM.—Mr. J. J. Bennett, the Curator, has just issued his annual report for 1869. The principal business done in the department during the year has been:—The re-arrangement of a portion of the presses of the general herbarium; the re-arrangement of certain orders of *Apetalæ* and *Endogens*, and of the *Lichens*, both British and foreign, with numerous additions to each; the selection of a very large number of specimens from the herbarium of the late Mr. M. B. Ward, and from the collection of Abyssinian plants sent by Dr. Schimper through the Foreign Office; the naming, arranging, and laying into the general herbarium of Berlandier's Mexican collection, of Linden's collection from New Granada, Tate's from Nicaragua, Coulter's from California, Sartwell's *Carices* of North America, Wright's collections from the Neigherry Hills and from India generally, Jameson's from the Andes of Quito, *Orchidææ* from different countries, Ferns from the islands of the South Pacific, and of a large number of miscellaneous specimens of various families and from different countries; the examination and arrangement of the recent and fossil *Coniferæ* and *Cycadææ*; and of Mr. Brown's collection of fossil woods; the arrangement and incorporation in the general herbarium of a large number of European plants; the re-arrangement of various portions of the British herbarium, and of the collection of fruits and seeds; and the re-arrangement of various parts of the collection contained in the Exhibition Rooms, and especially of the cases containing *Coniferæ* and *Cactææ*, with large additions. The most important additions to the collection during the year have been:—Upwards of 1000 European plants from the collection of Dr. Keston and the late Mr. N. B. Ward; 900

plants of Ingermannland; 300 from Sicily; 200 European Fungi; 200 Italian Cryptogams; 3000 plants of Abyssinia, collected by Dr. Schimper; more than 3000 plants of South Africa, from Mr. Ward's collection; upwards of 500 from Madeira, collected by Lemann and others; nearly 1000 from the mountains of Altai; 1000 from India, collected by Dr. Wright; 400 from Malacca, collected by Griffith; 100 from the Feejee Islands, collected by Harvey; 1000 from North America; 400 Fungi of South Carolina; 300 plants from Nicaragua, collected by Tate; 700 from the Andes of Quito; a fine set of Pine cones from California; numerous specimens of plants and fruits, chiefly from Africa. The number of visits paid to the herbarium during the year for purposes of scientific research was 974.—(Nature.)

PROLIFIC STANDARD APRICOT TREE.

MR. RIVERS, of Sawbridgeworth, has obliged us by the following for publication:—"Knowing you take an interest in all kinds of trees, I write a few lines to give you an account of a standard Apricot of the Breda kind that I believe I had from you rather more than twenty years since, and which, if you think it out of the ordinary way, you can make known to the gardening world. I give you my word that I state no more than facts; anyone is welcome to see the tree with the crop now on it. Last year it bore the worst crop I have ever known, there being barely one dozen fruit. Three or four years since it produced rather over two bushels; this year I estimate the crop to be at least three bushels. The quality is excellent for preserving or culinary purposes. It is growing on a lawn not protected by anything. The site was, in my recollection, an Asparagus bed. The tree has a very handsome head, as large as that of a good-sized Apple tree. It is still in a growing state, and not nearly the size it probably will attain.—ANTHONY BURN, *Whitcombe Court, Gloucester.*"

[The tree is about 6 feet high, its stem 2 feet 3 inches in circumference, and the branches overshadow a circle rather more than 31 feet in diameter.—EDS.]

NOTES OF A HORTICULTURAL VISIT TO CALIFORNIA.

(By Marshall P. Wilder, Charles Downing, George Ellwanger, and P. Barry.)

Quality of Californian Fruits.—As a general rule, the fruits of California are superior to ours in size and beauty, but rather inferior in flavour. To this there are some exceptions. We think that the Cherries, Apricots, as well as early Pears and Apples, are as fine as can be produced in any country. The want of flavour is in many cases owing to the unripe condition of the fruit, premature picking, and improper ripening. The early fruits, not being of overgrown size, are generally of better quality than those of autumn; yet we are unable to say how far the want of flavour in these may be owing to improper treatment.

When we arrived in San Francisco the Apricot was very abundant and beautiful, as it was during nearly the whole period of our visit, but we were told the fruit were insipid. On taking some to our rooms and getting them fully ripe they were delicious, equal to any we ever tasted. Fruits on the market stalls are seldom fit to be eaten.

In the case of Strawberries, the best varieties, it seems, have not yet been adopted by the market growers. With the exception of the Currant, none of the small fruits seem to be as good as ours.

The Grapes grown are almost exclusively what we call foreign varieties. The Mission Grape, so called, is a foreign Grape, though improperly called California. Wild native Grapes abound in all the wooded parts of the State, but they are very different in character from the Mission. The practice is, among growers, to speak of the Mission as not being a foreign Grape. American Grapes have been tested in a few cases, but, as far as we could ascertain, with unfavourable results. We do not, however, regard the few experiments we heard of as conclusive, and think it quite probable that our Clinton, or some of its class, might be employed successfully to make a lighter wine than any they now make, and which is so much needed to take the place of imported claret now in general use.

Garden Vegetables.—The supply of culinary vegetables, as seen in the markets of San Francisco and other cities, is very abundant and of excellent quality. What surprises visitors

from the east is to find such articles as Celery in the market all summer. Crop after crop can be obtained in varied succession, so that you may find anything you desire at any season. Asparagus is cut from February to June. One grower informed us he had six acres. The product was about 5 tons to the acre, and contracted at 9 cents per lb. The size to which vegetables attain is almost incredible. We were told of Pumpkins weighing 250 lbs.; Squashes, 150 lbs.; Beets, 200 lbs.; Carrots, 30 lbs., &c. It is easy to understand how these results are obtained in a climate where growth never ceases. The mean temperature of the coldest month, December, at San Francisco, is said to be 55°. In the interior it is probably lower.

Ornamental Trees and Plants.—On arriving in California we were at once struck with the character of the trees and plants which we saw in the gardens, public streets, &c.

Instead of the Elms, Maples, &c., which prevail at the east, we saw the Australian Acacias and Eucalyptus, and the Mexican Pine, insignis, and Monterey Cypress, *Cupressus macrocarpa*. These are everywhere planted as the common trees. Nurserymen informed us that the first trees asked for, and in many cases the only ones asked for, by persons beginning to improve their city or suburban lots, are the Eucalyptus, Acacias, *Pinus insignis*, and *Cupressus macrocarpa*. The reason for this is, that these trees grow rapidly, transplant easily, and are adapted to the climate. We were told that the *Pinus insignis* is so easily transplanted that if the roots but touch the ground it will grow. The Eucalyptus and Acacias grow there as Willows do with us. In the grounds of Mr. William Patterson, a nurseryman of San Francisco, we saw Eucalyptus globulus, called the Blue Gum, six years old, which was 50 feet in height, and 5 feet in circumference of stem. A *Pinus insignis* of the same age was 40 feet high.

The *Cupressus macrocarpa* is more prevalent than any other tree that is planted for ornament either in city or country. We have even seen it employed as a street tree, pruned-up 6 or 8 feet, and the heads shorn into sugar-loaf form. The Acacias are frequently used in the same way, and although stiff and formal they look very well. The Cypress retains all through the long dry summer a charming verdure, when not stained by dust, as it often is in the streets. The Eucalyptus grows so rapidly that it is being planted for wood. We saw an account of one plantation of fifty acres planted 8 feet by 8 feet, for timber. There is ample scope for plantations of this kind.

In Mr. Patterson's grounds, already referred to, we noted a hedge of *Acacia lophantha*, 25 feet high and 4 feet through; a *Fuchsia* hedge, 10 feet high, the stems of the plants as thick as a man's arm; a hedge of *Veronica Lindleyana*, 10 feet high; beautiful specimens of *Araucaria imbricata* and *Cookii*, 10 feet high; fine trees of the *Guava* in blossom—the fruit ripens there in September; also the Camphor tree, and many other species we are not accustomed to see in the open ground.

Here we saw a superb show of Roses; the best we saw in the State, we think. *Eliée Sauvage*, Tea, was named as the most valuable for a constant supply of cut flowers.—(Moore's *Rural New-Yorker*.)

THE AMATEUR GARDENER.

(CHAPTERS NOT IN WALTON.)

No. 5.

SYLVIA.—I cannot tell you, Clericus, how much I am often interested in watching the minute insects which fall upon the pages of my book as I sit beneath the shade of yonder spreading *Acacia* on a bright summer's day. First, perhaps, the merest speck of a spider spins its thin cobweb from an overhanging branch, till in graceful undulations it alights gently upon the printed page, followed, probably, by a fly of such diminutive organisation that it almost requires a microscope to distinguish its ganzy wings which give it its motive power; anon a small green caterpillar descends from its ambitious position overhead, weaving its own coil of silken cord, by which it descends with an occasional spurt, as though it summoned up all its strength to effect its downward progress, and render its eventual fall as gentle as possible.

CLERICUS.—Yes, and each of those tiny insects must have the physical organisation of a larger being to enable it to effect its voluntary motion. Truly God's power may be seen as much in the ant as in the elephant, in the mite as in the whale.

HORTATOR.—How wonderful is the instinct which guides such minute beings!

CLERICUS.—Instinct! What a door of thought is thrown open at the mere mention of that mysterious word! What is the line of demarcation which separates instinct from reason? This is a barrier that the keenest philosophy has never been able to burst, nor the madness of atheism ever been able to explain.

CIVIS.—And then, too, what wonderful mechanism!

CLERICUS.—Yes. Paley says that out of the millions of designs which meet the inquiring eye of the natural philosopher, every one has a benevolent intent.

CIVIS.—Pray tell me, my good master, what is the name of yonder dark evergreen, which has such a stately growth, and which you seem to have banished as far as possible from the precincts of your villa?

HORTATOR.—That is *Wellingtonia gigantea*, a native of California, which has but lately (comparatively) been naturalised in Europe; and it is planted so far away because in course of years it might, probably, grow so large as to compel its being cut down if it grew nearer to the dwelling-house. In its own country specimens have been found fully 350 feet in height; and though in this climate it will probably never attain such a prodigious size as that, yet the rapidity of its growth in England gives fair warning that even here it will eventually assume gigantic proportions. But I am glad that you have drawn my attention to it, my good scholar, because it leads me to give you a word of warning, to be careful not to plant your evergreens, especially specimen plants, too closely in your garden in your projected new villa—there cannot be a greater mistake.

CIVIS.—But how miserably unclothed and bare a new garden looks when only small bushes are planted here and there.

HORTATOR.—Yes, that is the bait which leads so many, even among good gardeners, to fall into the trap of planting shrubs too closely; they are anxious to give a finished look at once to the grounds, forgetting that in a few years evergreens which would have proved splendid specimen plants will be dwarfed or spindled. Another very common error which amateurs are apt to fall into, and from exactly the same reason, is that of procuring large handsome plants instead of small ones, being ignorant of the fact that it is always the safer policy to plant younger plants, as they soon outstrip the elder, and shame their giant brethren by their healthy and luxuriant growth, while the Goliaths look wan and miserable, and often die altogether from a wasting consumption, to the heavy pecuniary loss of the amateur, for large plants are always expensive, and never satisfactory.

CIVIS.—Thank you sincerely for your hints. Is there anything else which appears necessary to the success of planting shrubs?

HORTATOR.—Yes, the careful preparation of the ground; be sure that it be deeply dug. I have frequently turned my eyes away in disgust when I have seen mere holes made, and shrubs thrust in without any further preparation of the soil, which should be enriched with thoroughly decomposed manure, when it is what the gardeners call "double-dug."

CIVIS.—You would not, I suppose, my dear master, Hortator, confine the planting in the pleasure-land entirely to evergreens?

HORTATOR.—Certainly not. A judicious planting of the finest deciduous trees is absolutely necessary to the better development of the Coniferae, &c. I once paid a visit to the celebrated gardens of evergreens at Elvaston Castle, near Derby, and I cannot describe the depressing effect which those acres of unbroken green had upon the spirit; for although the trees and shrubs were of the choicest description, and for the most part judiciously planted, yet the *tout ensemble* was perfectly funereal, and one seemed to expect a tablet "in memoriam" at every step one took; and it by accident the eye fell upon a bright flower, it was like a gleam of sunshine through a thundercloud.

CLERICUS.—Tell me, Hortator, did you ever see the splendid Purple Beeches in the gardens of the Earl of Stamford at Enville, in Staffordshire?

HORTATOR.—Never; but of their beauty I have often heard.

CLERICUS.—They are, indeed, worth travelling many miles to see when in their early summer beauty, when their regal robes of purple sweep the velvet lawns of those superb gardens, and seem conscious of the dignity which their august presence adds to that fairyland.

HORTATOR.—Should you, Civis, wish to learn much of forest trees, I would recommend you to study good John Evelyn's "Sylva;" and should you become much interested in him and his admirable diary, I would advise you to pay a visit to Wotton, in Surrey, the residence which that good man de-

scribes with so much feeling, and which, by kind permission of the present proprietor, Mr. Evelyn, a descendant of the celebrated writer, is open to the public on a Saturday. I can assure you, you would thank me for my advice.—HORTATOR.

FUNGUS EATING.

If we were to search the wide world I do not think that it would be possible to find a nation more prejudiced than ourselves. We boast of our enlightenment and the liberality of our views; but, when we come to the practical, it takes an immense deal of leverage to move us out of our beaten track; and, even in the common habits of our lives, we go on to the end of the chapter as though there was but one way of doing things.

In the little matters of eating and drinking we are perfect slaves to our cooks; and whether it arises from indolence, timidity, or ignorance, the result is the same—that few of us dare try experiments; whereby a great quantity of palatable food remains unknown and uneeded. This is particularly the case with the class of comestibles which forms the subject of my paper—viz., that of the Fungus; the true knowledge and appreciation of which would keep starvation from many a poor man's table (at least during three months in the year), and give the gourmand an additional luxury wherewith to tickle his palate. The apathy, ridicule, or disgust with which a serious proposal to cook and eat Fungi is received, is the more extraordinary because so much has been said and written about them; therefore it cannot be altogether from ignorance of the subject. Dr. Badham, Messrs. Cooke, Worthington Smith, Berkeley, and others have expatiated well and fully on the whole tribe of Mushrooms and Fungi; and, even for those who cannot screw up their courage to the crucial test of eating them, the works of these authorities are full of interest. More recently, too, the great Fungus question has been examined in the most practical manner by the members of a Natural History Society in the West of England, called the Woolhope Club, which has its head-quarters at Hereford, and embraces in its scientific investigations all the district between Shropshire and the Bristol Channel. Geology and botany are the main studies of this Society, but lately that of mycology (the study of Fungi) has been added, and a most useful and important one it is. One day in each autumn is devoted to a Fungus hunt through the prolific woods of Herefordshire, and the numbers that are gathered by this enthusiastic band are something enormous. The labours of the day are closed by a dinner, at which the main dishes are composed of the spoils of the chase, dressed in the most epicurean fashion, and with the most appetising (Fungus) sauces; and as I have myself assisted at these Apician banquets, I can vouch for the delicacy of the viands, and the absurdity which we daily commit of turning up our noses at the good things with which Nature has supplied us. But the Woolhope Club does more than eat and talk, for it publishes (though only privately) an annual volume of its transactions, including a description of the Fungi of the county, and the best modes of cooking them. These descriptions, and the illustrations which accompany them, are mainly due to the energy and experience of Dr. Bull, of Hereford, who has been the chief instrument in making the Woolhope Club a Fungus-eating community, and who rivals Soyer himself in his ingenuity in discovering new ways of cooking his favourite food.

Seriously speaking, however, I consider the endeavour to make the public understand the value of the Fungus to the nation so very important, that I shall draw largely upon the Woolhope experiences, as well as those of other writers, in the hope that the readers of the "Food Journal" will really try experiments for themselves. With the uninitiated in such matters there is, not unnaturally, a nervous reluctance in taking the first plunge; for, to the minds of most people, a Toadstool is only another word for rank poison, while a Puff-ball suggests horrible tortures by inordinate swelling, until the wretched victim bursts. This, I remember was one of the warnings in early life, not to meddle with suspicious Mushrooms. But, although there is some grounds for distrust (as there is in most other things), a little inquiry will show how fearfully the danger is exaggerated. The Rev. M. Berkeley gives us a list of 2380 different kinds of British Fungi, and even then does not include those which require a microscope to distinguish their peculiar characters. Out of this large number he ranks ten only as poisonous, and six as doubtful. He does not imply by this that of all the 2380 every one is eatable—for

this is very far from being the case—but simply that they are not poisonous; and that is the first and the greatest point which we have to combat. It is unfortunately the case that some of the most poisonous are the most common; for, as Dr. Bull observes, "There is scarcely a field, and, perhaps, not a single wood, in the country that does not abound with several varieties of the *Coprius*, the *Agaricus fascicularis*, the beautifully coloured *Riz-sula emetica*, and several others. But, since they are so abundant, it is peculiarly our province to encourage the study of mycology; and thus lessen the prejudice existing against them all, by clearly showing the means of distinguishing which are good and which are bad. This is a matter of some difficulty, for the scientific differences are too minute for ready distinction. We cannot be guided by the place they grow in; nor can we eat after slugs, as we do after wasps and birds with fruit, for slugs seem to enjoy the most poisonous kinds. Colour gives no distinction, nor is the smell or taste of the *Fungus* an infallible guide. It is freely acknowledged, therefore, that there are poisonous Mushrooms, and that, unfortunately, they are exceedingly common; but this is surely no argument for neglecting the far greater proportion of what may be made wholesome food. We might, on this ground, refuse to eat Potatoes, because that plant belongs to a family containing virulent poisons. Parsley, too, which is the most familiar garnish that we have, is not regarded with suspicion because the Fool's Parsley, which grows in many gardens nearly as freely, is poisonous. We eat Horseradish without thinking twice about it, although a year seldom passes without somebody being poisoned by accompanying their roast beef with scraped Aconite root, which is so like Horseradish that it requires a little care to distinguish between the two.

The question, therefore, resolves itself into this, that—whether it be Horseradish, Parsley, or Fungi—everybody, whether of high or low degree, ought to have that instruction in common things which should make it impossible for such mistakes to happen. While in our public schools we pretend to give instruction in chemistry and physics, it is inconsistent that we should ignore the study of simple geology and botany, the knowledge of which in strange countries is of incalculable importance; and the value of such elementary knowledge in schools of a lower class can scarcely be overrated. "A little knowledge is a dangerous thing," is a proverb that is often quoted by well-meaning people as a warning against this sort of instruction, as tending to make the recipients thereof smatterers, conceited, and presumptuous; but surely to teach a village child what Fungus he may gather for the cottage dinner without danger of being poisoned, is as useful knowledge as the height of the Himalayas or the date of the battle of Navarino. I am aware that there are plenty of facilities for this teaching in the way of cheap illustrations, such as those by Mr. W. G. Smith; but I cannot find that such teaching is anywhere made compulsory, or indeed is adopted at all, except in isolated cases.

Foreigners are far before us in appreciating the value of the Fungus as a food supply, and notably in France and Italy; although, with a due regard to the public safety, Fungi are allowed to be sold only when passed by the inspectors of food; with this regulation we certainly should not quarrel. Mr. Story, in his interesting work "*Roba di Roma*," tells us that one of the most common articles of sale are baskets of Mushrooms. "There are the grey *porcini*, the foliated *alberetti*, and the orange-hued *ovole*; some of the latter of enormous size, big enough to shelter a thousand fairies under their smooth and painted dome. In each of them is a cleft stick, bearing a card from the inspector of the market, granting permission to sell them; for Mushrooms have proved fatal to so many Cardinals, to say nothing of Popes and other people, that they are naturally looked upon with suspicion, and must be all officially examined to prevent accidents. The Italians are braver than we are in the matter of eating; and many a Fungus which we christen with the foul name of Toadstool, and ignominiously exile from our tables, is here baptised with the Christian appellation of Mushroom, and is eagerly sought after as one of the cheapest and most delicious of vegetables." In Milan, too, the *porcini*, which in English botanical phrase is the *Boletus edulis*; the *ovole*, the equivalent of the *Agaricus cæsareus*; with some few more, are openly sold under inspection. I will conclude this article with a quotation from "The Esculent Fungues of England," by Dr. Badham, one of the most persevering inquirers, and as audacious an experimenter as this country has ever produced. Describing his rambles in 1847 he says, "I have seen this autumn whole hundredweights of rich wholesome

dial rotting under the trees; woods teeming with food, and not one hand to gather it; and this, perhaps, in the midst of Potato blight, poverty, and all manner of privations, and public prayers against famine. I have indeed grieved, when I reflected on the straitened condition of the lower orders, to see unused pounds innumerable of extempore beefsteaks growing on our Oaks in the shape of *Fistulina hepatica*, with *Agaricus fuscipes* to pickle, in clusters under them."

Making allowances for a certain amount of enthusiasm, the question is certainly sufficiently interesting to urge us to do our best towards introducing this new food, at present wasted; not only by learning to distinguish the good from the bad, but by practically making the trial at our own tables. For it must be remembered that it is all nonsense preaching to the poor to try this and that, unless the rich do it themselves; for the former are not only more ignorant, but ten times more prejudiced, and, in many cases, the facility of getting them for nothing would be rather a hindrance than an inducement to make the experiment.

Still, if a demand should arise for Fungi, and the poor were to find that they were saleable articles, they would very soon begin to try for themselves what they were like; and in this way, with the most ordinary teaching and care, we might largely supplement the national larder.—PHILLIPS DEVAN.—(*Food Journal*.)

NOTES AND GLEANINGS.

A custom prevails at Easingwold in Yorkshire which we never met with anywhere else. Having occasion lately to visit that now-deserted town, we observed in the churchyard plates and dishes, containing gathered flowers in water, placed on the graves. This, we were informed, was done by the relations of the deceased. Sheep were grazing within the bounds, and not infrequently ate up the flowers and broke the plates, but these were, notwithstanding, constantly renewed. Our companion was unable to inform us of the origin or object of this practice, and merely remarked that it was an old custom.

— Two of the best MELONS we have met with this season are the VICTORY OF BATH, grown by Mr. Gilbert, gardener to the Marquis of Exeter, at Burghley; and the GOLDEN GEM, raised by and cultivated by Mr. Cox, gardener to Earl Beauchamp, at Madresfield Court. The former is a green flesh and the latter a white flesh, and both are of very superior excellence. Their size is large, and they are finely and beautifully netted.

— On a visit we lately made to Madresfield Court, Mr. Cox, who, by the way, is the fortunate raiser of that exquisite Grape the Madresfield Court Muscat, showed us the superiority of the fruit of VICTORIA NECTARINE grown against a wall in the open air to that grown under glass in a Peach house. That produced in the open air is very dark-coloured, and with a very rich and piquant flavour, while that grown under glass is much paler and comparatively flat, being far less rich. In either case the fruit was quite sound, and showed no disposition to crack, as its parent the Stanwick is so liable to do. In all situations where Nectarines can be grown successfully, we would recommend planters to make use of the Victoria.

— A CORRESPONDENT writes—"Yesterday I went to Eastnor Castle and saw the MISTLETOE ON THE OAK. This was the first time that I had ocular confirmation of what I had heard of. There are four large bunches near the top of the tree. This is the only example that is known in the Eastnor large Oak woods." Another correspondent, "VEVEY," says, "I noticed that you mention the few cases in which the Mistletoe has been found growing on the Oak. I have seen it more than once growing on that tree in the Canton of Vaud, Switzerland. I have also seen it on the common Norwegian Fir."

PROPOSED BOILER.

As an amateur gardener on a small scale, I have been much interested during the last year or two in the notices of various boilers and hot-water apparatus which have appeared in the Journal and elsewhere, and in the remarks which have been made on conduction, convection, &c.; also in the question as to the economy of flues or pipes for small houses, the result being the invention of a boiler which in simplicity, efficiency, economy of fuel, facility of setting and management, may be advantageously compared with any other. Having gone to

have heard of and seen some wonderful boilers, but somehow the wonderful soon becomes the rather common and everyday affair. That your boiler is a good one and easily managed we do not doubt. It is just the old upright cylinder boiler with these little differences: The fireplace on which it is placed is rather larger than usual; the top of the boiler is nearly double the width of the base, spreading regularly out to that width. The upright cylinder inside is of the usual regular shape, but that is appropriated almost entirely to the holding of fuel, which drops down as it is consumed, the heated air, it is true, passing partly through the fuel; but the chief heat from the fire passes directly from it through flues round the sides of the boiler, meeting over the top, and thence into the chimney. We have no doubt that by filling this cylinder with fuel the fire will last a long time, if you moderate the draught at the ash-pit-door. We believe that when fairly set going you will have little smoke, as the fuel will be well heated and carbonised before dropping into the fireplace, but with these advantages there is this disadvantage, that there is but a small part of the boiler exposed to the direct action of the red-hot fuel in the fireplace.

We should be very sorry to damp the aspirations of anyone, and especially an amateur, but having registered your invention we would let well alone; and if you asked our advice, it would be not to waste money on a patent. In your plan there is nothing new. For years back we have had sections of boilers sent to us, some as simple, and others much more complex than yours, and having the peculiarity of making the inside of the cylinder chiefly a fuel-box, so that you might have trouble enough with your patent if ever you should want to protect it. As a warning we may mention two facts—First, in a celebrated nursery we lately saw standing a substantial double saddle-back boiler, invented by one of the firm, and which had answered very well with them, yet, notwithstanding their influence, they have not yet sold enough of them to pay the first cost of moulding and casting. The second fact is, that some of the greatest gardeners in the country, after trying all kinds of boilers, are actually falling back on the common saddle-backs, and depending chiefly on the direct action of the fire, and regulating draught by the ash-pit-door and the damper. Provided a boiler is well set, a first-rate stoker will well make almost any boiler the best for a continuance.]

WORK FOR THE WEEK.

KITCHEN GARDEN.

CONTINUE to destroy weeds wherever they appear; clear away all decaying leaves from Broccoli and Brussels Sprouts, and have them or any decaying vegetable matter, at once trenched into unoccupied ground; still, the extent of unoccupied ground in a well-managed kitchen garden ought at this season to be very small. Prepare a quarter of ground for the main crop of Cabbages for next May, June, and July. Let it be thoroughly manured and trenched, as they will have to remain perhaps twelve months in the same spot, for if well managed they will produce after cutting an abundant crop of greens of the Colewort character. If ground and plants be to spare, a great quantity of the Early York should be planted out in well-manured beds or borders at about 6 inches apart; these will be "in cut" before the early Cabbage comes in, perhaps by the end of March. The Cauliflowers sown in August will be getting gross; they should be removed forthwith. Some persons pot them, and doing so is an excellent plan for the earliest lot. They may be kept thus in a cold frame or pit until the beginning of February, when they may be planted under hand-glasses. Those for succession crops if growing too strong may be pulled up, thrown on the ground for half an hour to check the fibres, and then be planted out in poor soil where they are to remain. To prevent the attacks of slugs on young Cauliflower and Lettuce plants, mix soot and lime in equal quantities, and dust them over with this once or twice weekly. We must now expect frost very soon, and ought to prepare accordingly. Lettuce, for instance, just coming into use may be lifted with balls and placed in frames. Look over Onions that have been stored, and remove any that are beginning to decay. Make the last out-door sowing of Radishes, which, if the winter do not set in early, may prove useful. Let the latest-sown Turnips have a thorough thinning and weeding. In late situations where Tomatoes are just ripening let them be gathered or ripened-off in the houses, as the least frost is fatal to them.

FRUIT GARDEN.

If wet weather set in let the Strawberry plants in pots be

protected either by turning the pots on their sides or by placing them in cold frames, but in either case so that worms may be excluded. Continue to collect late varieties of Pears and Apples. Walnuts are also quite fit to gather. Attend to Apples in the fruit room as before directed.

FLOWER GARDEN.

The time is at hand for alterations and the planting of choice shrubs. Where extensive alterations are contemplated, more especially in planting flowers, observations should be made before the flowers lose their character and the trees and shrubs are stripped of their foliage. Cuttings should be carefully looked over to see that nothing has been omitted, and that a sufficient quantity of everything is in a promising state for making good plants before winter. It should be borne in mind that plants which are at all difficult to winter if rooted after this time may be considerably thinned before spring, and also that they will not be sufficiently strong to furnish cuttings for spring propagation; consequently a larger quantity should be provided than would have been necessary had the cuttings been put in six weeks ago. If there is a reserve stock of strong plants in pots, to have which is a safe practice where many bedding plants are required, and if there is proper convenience for growing them and propagating in spring, they will furnish a large number of cuttings next March, and become as good plants by turning-out time as cuttings put in now. In the case of such plants as Ageratum, Petunias, Heliotropes, and dwarf Lobelias it is useless wintering young stock, as they grow so freely in heat, and are so easily propagated from soft cuttings, that a few good-sized old plants, which require but little room or attention in winter, will furnish a very large quantity of plants by bedding-out time. Attend to the potting of cuttings sufficiently rooted, and give every after-attention to them in order to have them well established. Persevere with leaf-sweeping and other routine work.

GREENHOUSE AND CONSERVATORY.

Chrysanthemums intended for the decoration of these structures should be placed under cover at once and receive every attention. Regular watering is one of the most important matters, for if allowed to become dry, if only for a few hours, decay or yellowness immediately takes place in the under leaves. They will from this time enjoy liquid manure constantly, provided it is perfectly clear and weak. All suckers should be pulled away as they are formed. See to thorough staking here, and the extermination of all insects. Large specimens of the following make a fine figure at this period:—*Buddleia Lindleyana*, *Gesnera lateritia*, *Salvia patens*, *Begonia incornata*, *Phlox Drummondii*, *Ipomoea ficifolia* (trellis), *Thunbergias*, *Plumbagos*, *Justicias*, *Clerodendrons*, &c. Stocks and Mignonette sown a few weeks ago may now be transplanted, especially the Stocks. If any early bloom is desired, half a dozen plants may be put into a well-drained 5-inch pot. The last shift should now be given to forward *Cinerarias* intended to bloom this autumn and early in spring; use most liberal drainage, and put them under cover close to the glass, with a free circulation of air. *Tagetes lucida* is a good late-flowering plant; although of long standing, it is not so generally known as it deserves to be, and grown in pots it makes a good display in November, the flowers being a rich yellow. Tie *Azaleas* into form as soon as can be done, in order to give them a neat appearance. Look carefully after the watering of large hardwooded plants in pots, especially Heaths, which are soon injured by being either over or under-watered. Examine the specimens often and carefully, and when they are found to be dry water thoroughly, so as to moisten the whole of the ball; also look sharply after mildew on softwooded Heaths, and dust the plants with sulphur directly the enemy is perceived. Look carefully after red spider on Brassicas, *Chorozemas*, and anything else found to be liable to the pest. Red spider is easily got rid of by laying the affected plant on its side and well washing the under sides of the leaves with the engine, applying the water with as much force as the foliage will bear. Repot strong-growing *Pelargoniums*; plants fairly established after repotting can hardly be kept too cool. Keep tree Violets clear of their great enemy, red spider, by a liberal use of the syringe, and give them plenty of manure water, which will assist in keeping them in vigorous health. *Primulae* must also be carefully attended to, in order to encourage them to make rapid growth.

STOVE.

The stove, as well as other gardening structures, partakes in general of some re-arrangement at this period, when the

general cry is "House all tender plants;" while such is proceeding, let all plants that require it be properly staked where necessary, as well as freed from insects. Young stock of *Begonias* for winter flowering may still be shifted. Some of the bulbous tribes will now begin to waken from their dormant state, and some will speedily show blossom; these, when fairly started, if pot-bound, may receive a shift, using a compost of sandy loam and vegetable matter; a little bottom heat would be of service after this operation. Keep the atmospheric temperature moderate at this period, and give liberal ventilation. —W. KEANE.

DOINGS OF THE LAST WEEK.

SUCH a week of sunshine that but for slight frosty mornings and a few leaves falling from Chestnuts and Elms, in the flower garden we might imagine we were in the first days of August instead of approaching the end of September. Everything seems to betoken that the end of autumn is approaching, as from the dryness and heat of the summer all deciduous trees will lose their leaves earlier than usual. Many evergreens, too, suffered from the drought, and there could scarcely have been a more unpropitious season for trees and shrubs planted in spring; and where, owing to circumstances, no water could be given them, many not convinced before, will be satisfied now of the importance of early autumn planting when it can be attended to. Last autumn in this district such a thing was impossible, as the plants were far too dry to be raised, and the ground when turned up for planting was little better than so much dust. Without heavy rains the soil will be little better this season, but where the rains have been plentiful, or if they come before the weather is much colder, there will be a most favourable time for early autumn planting, as the summer's growth will be early matured, and the ground will be warmer than usual to encourage fresh rooting.

KITCHEN GARDEN.

It is always well to have enough, and it is more pleasant to pull up what may not be wanted than to find the want of anything. Even small plants of *Endive* and *Lettuce* planted out now in spare places, as among bush fruit, may stand the winter well, and if many fail it will only be the trouble of planting. Winter and spring Lettuces are considered great delicacies by some, and had we room we would now take up with balls a number of plants 3 or 4 inches high, and plant them where they could have the protection of glass in winter. It is on the whole waste of space to plant them too thickly; they should not be less than 12 or 15 inches apart when we wish them to grow and form fine individual specimens. It is enough to make one envious to see whole ranges of cold pits thus filled with young Lettuces, the lights all off, but ready to be put on at the first approach of frost or of heavy rains, but plenty of air given in the latter case. The treatment of such plants ought to be quite different from that of full-grown Lettuces and *Endive* taken up towards the end of next month, and which may be placed quite close together, in order to be used as wanted. Small plants turned out now in cool unheated orchard houses will come in very useful early in spring.

Cauliflowers.—We have strewn some charcoal dust and a little lime and soot among our young small *Cauliflower* plants, as they did not seem altogether right, and showed some signs of mildewing. These we shall prick out thickly in a bed in fresh light soil before transferring them to the hand-glasses or pots for the winter. Succession crops of *Cauliflower* for present and late autumn use we have been obliged to refresh with sewage water; they so hung their leaves in the bright days as to leave the heads, not quite full-grown, exposed to the fierce sun, which has a tendency to make them harder than they ought to be. All vegetables, to be good, should be used soon after they are cut. Many complaints are the consequence of allowing vegetables to remain for some time before cooking them. Even a *Cabbage* cut and taken to the pot is altogether different from a *Cabbage* cut and allowed to lie for a day or two. We have known thorough admirers of the *Cucumber* who would have known if their favourite kind was cut more than half an hour before it appeared at the table. When vegetables are cooked a little more time after cutting is of less consequence. No keeping treatment afterwards entirely makes up in flavour and crispness for cutting fresh and just when wanted.

Cabbages.—These are growing, if anything, too well, as, except *Coleworts*, we do not wish the early crops for next season to be too forward before winter, as there is then a greater likeli-

hood that they will bolt in the spring, instead of making fine heads. Caterpillars, so ruinous in many places, have troubled us but little; but when we thought we had got rid of clouds of fly by syringing, &c., we find it is coming again, though in but small patches, and the same remedy must be again applied. Small plants of *Cabbages* pricked out rather thickly now in poor soil will make much more serviceable plants for spring planting than if they had been left in the seed bed.

Forking and hoeing all ground amongst young growing crops will greatly promote free growth.

FRUIT GARDEN.

As soon as we have time we shall clear away all runners and litter from *Strawberry* plantations, merely pricking over with the points of a fork the surface soil between the rows, and mulching with rotten dung; better for the purpose, when they can be obtained, are fresh horse droppings, laid in a heap long enough to heat and destroy what vitality may be in the oats that have passed into the droppings. Even old Mushroom-bed dung is good for such a purpose, but nothing answers better than the droppings, though few can obtain them for such a purpose. When thus used the droppings need not be put on so thickly as rotten manure. Even a dressing of a couple of inches of manure becomes very thin before spring. We greatly prefer that all such manure as surface-dressing should just remain on the surface instead of being forked in, however slightly. The crowns of the plants should not be covered, but the manure may rise higher in the middle of the space between the rows. Those who put on such a dressing for the first time will be surprised how little there is left of it in spring. A slight clearing away of dead leaves in spring, with a little of the roughest of the mulching, will leave all neat.

New plantations of *Strawberry* plants may now be made, but if the plants are good, less importance attaches to the time of planting than to the condition of the ground, which ought to be well trenched, manured, and then partly solidified on the surface before planting. As in everything else, there is an advantage in early autumn planting, and if the plants are turned out of pots all the better, as they soon establish themselves in their fresh quarters, and may be expected to bear well in the following summer. Where, however, ground is scarce we can recommend the following plan. Take off the runners as soon as they show roots, prick them out in a bed made light and rich on the surface to the depth of 4 or 5 inches, by adding rotten dung, leaf mould, and some light sandy matter, and let the plants be from 6 to 8 inches apart. Shade a little at first, and when the young plants can take care of themselves give all the sun and heat possible, and waterings when needed. On ground heavily cropped until Christmas we trenched, dug, and re-dug until it was in a finely-pulverised rich condition by the end of February, and then we have lifted these plants with balls, and transferred them to the fine mellow soil, and had as good returns in June as if we had planted in the autumn. Many such schemes must be resorted to where the most has to be made of a little piece of ground. The labour is, doubtless, increased, but the ground is made to yield more.

Strawberry plants in pots for forcing need less watering now, as the aim, in the forwardest especially, should be to ripen the buds or crowns. We must try and give ours a little more room, as the large foliage—quite large enough—is too close together.

As the nights are becoming colder, it is as well to give any watering that may be required about 9 A.M., as the soil, if fresh watered, gets cool in a clear night. The same rule applies to all watering, just as in the hottest weather and the longest days it was advisable to water in the afternoon and evening. Such a system could not easily be carried out with the present stereotyped hours for gardening and agricultural labour, but often in hot weather one watering after 7 P.M. in July and August would do more good than two similar waterings early in the afternoon. Often the little water we use had to be given at any time, just when we could get it, but then we had to resort to modes to prevent its quick evaporation which would not have been needed if we could have given the same water when the sun was low, and twilight and night approaching, so that the plant should have little or no strain on its resources.

Hardy fruits, as Apples and Pears, have been much improved in their appearance during the past week, obtaining that rich colouring which nothing but a bright warm sun can give. Some of our readers were so alarmed by what the late gale did in throwing down many of their fruit, that they gathered most of what remained forthwith, they say now to the great

loss in colouring and such due ripening as insures good keeping. We are afraid that the gale in some cases was only the apparent cause of much fruit dropping prematurely. Many thus dropped would be found not quite sound, but beginning to decay at the core, owing to maggots, &c. In other cases, though we hope not numerous, the Apple, though seemingly perfectly sound outside, has the inside streaked with a fungoid disease, something like the Potato disease. Before cutting up the Apple nothing of this is to be seen. Such Apples, and those that have been a resting place for the maggots, will naturally drop before the sound ones are ripe. Those which are sound we should think would keep well, as if not quite so large they will be more perfectly matured; but such numbers having fallen from large trees, people are apt to say the fruit will not keep this season. Owing to this and the heavy crop, Apples in some places can hardly be disposed of at any price. If this weather continue we should not like to gather all our fruit for some weeks, if the dryness do not again force the birds to go to them for moist food. Flies and wasps are bad enough, but they are nothing to the larger birds, who soon demolish the sunny side of the best fruit, if left to take their own way.

ORNAMENTAL DEPARTMENT.

What a pity frost may be expected soon to come! With the exception of withered tree leaves, the fore-runners of what we may expect, the flower garden is still in its glory—so much so, that we are chary in taking the necessary number of cuttings, and have been obliged to decline supplying others. Circumstances quite alter cases. We hear of gardens almost dismantled already, the Geraniums taken up and given away, or potted and boxed for future use, and the ground being prepared for bulbs, spring-flowering annuals, &c. In private gardens where the family leave in August and September, and never return before the season is over, such a plan may be adopted to the benefit of all concerned; but we hardly see how it can be adopted where there is a resident family, and where the garden is required to look well up to the latest day possible. We have frequently had the flower garden finer and richer, but for the falling leaves, in the end of October than it has been in the end of June, or even July. In all cases where there are such remembrances, clearing the beds and borders in September is quite out of the question. When such beds are to be supplied with early bulbs as well, two plans may be adopted. First, pot the bulbs, to be planted afterwards in patches or in regular lines; or set the bulbs far enough apart on some rich compost, and cover them several inches deep, and then when the beds are cleared, dug, and pulverised, move the bulbs, and plant with balls, and they will do almost as well as if planted out early at once. The getting the beds in good order, just as in the case of the Strawberries referred to, makes up for earlier planting.

Greenhouse Plants.—The most tender should now be placed under cover, and even the hardiest should be so placed as to be easily protected from heavy rains and early frosts. The roots in the case of frost will be in greater danger of injury than the branches. Camellias are apt to throw their buds, and Azaleas to drop their leaves, if the pots are much exposed to frost. All the Epacris tribe are more sensitive to cold than even the Cape Heaths; the former should be housed, and the latter, if in pits and frames, should be protected from heavy rains and sudden frosts. In tolerable weather the lights should be on at night, but air left on top and bottom. The free dews now might be rather much for them. We have noticed of late that some trees have thrown down quite a heavy shower in the clear mornings, making a puddle all round their base.

Propagating.—We lately said we liked to propagate all bedding plants without any artificial heat. In propagating Verbenas, &c., now, we like to give a little mild bottom heat. For instance, if we use an old Melon bed under a frame, we take out the soil and a portion of the top dung, turn over what is below, and add about a couple of barrowloads of fresh hot dung to each light, cover with a few inches of the old dung, and then surface with dry ashes. If we could have obtained enough of cuttings early we would not have taken them now, or given them heat.

From several letters we are sorry to find that we have not made some of the modes of propagating plain enough, as we are asked if we really think small cuttings of such subjects as Geraniums are as good as large ones? and again, Do we think a pot of cuttings as good in the spring as the same number potted off in the autumn? We clearly stated that where there

was a reserve ground, and large cuttings could be obtained without interfering with the flower garden, they would be the best, and if each were in a small pot it would be better still. But, then, if we cannot do the best we must do the next best. We use small cuttings, and keep them generally in cutting-boxes all the winter, because if we used the smallest pots we could not by any means house the number we required. We give Geraniums from 1½ to 2 inches each, and Verbenas, Heliotropes, &c., much less, and contrive to give them more room after the days lengthen in spring, but the great proportion of them are seldom honoured with a pot of any sort. Dry season and altogether, the plants have done so well that many will not believe that these large Geranium plants were small short slips 2 inches apart in boxes in the middle of September, 1869. These little plants, just nicely rooted before winter, generally do well in the following season, and grow vigorously as well as bloom profusely. Our Verbenas when they succeed well are cut over in spring, much as we would do Mustard and Cress, for cuttings, for though the plants struck so thickly in autumn answer well, the spring-struck cuttings succeed better in our estimation. Whoever, then, has room and convenience cannot err if he can pot and establish in pots all his bedding plants in the previous autumn. We wish, however, to show that there need be no despair if we can find the means of wintering a great many thickly set in pots or boxes. We have frequently alluded to the best mode of taking up and wintering old plants of Geraniums.—R. F.

TO CORRESPONDENTS.

* * * We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By doing so they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

NAMING FRUITS.—We have repeatedly requested our correspondents not to send more than about six specimens to be named, for to identify them accurately requires much consideration, and consequently time. Yet we have now before us three baskets containing respectively twenty-nine, twenty-three, and seventeen specimens. From them add all such numbers we can only take a fraction for naming, and it annoys us not to be able to do all we are asked to do by our correspondents.

CLEANING LINUM AND PHLOX SEEDS (T. E. M.).—The best plan we know is to lay them on a floor, beat with sticks, and when all the seeds are out to sift through a sieve to free them of the husks; finally winnow. The wind will answer very well for a purpose of this sort. Having spread a cloth, let the seeds and dust fall from a height of 3 or 4 feet, and the chaff will be taken off clear of the sound seeds by the wind. We do not know any seedsman who purchases small quantities of seeds collected by private individuals. Write to some seedsman, telling him what you have to dispose of.

GATHERING QUINCES (Idem).—When they part freely from the tree, as they will do at the beginning of next month, they should be gathered, and not only on a fine day, but, if possible, after continued fine weather.

WINTERING CARNATIONS IN THE OPEN GROUND (A. H.).—Your best plan will be to plant them out, if well-ripened layers, in moderately light soil in an open sheltered situation, affording them the protection of hoops and mats in very severe weather. Could you not pot them and winter them in a cold frame?

GYMNOGRAMMA CALOMELANOS WITH PARTLY GOLDEN PINNÆ (Hafford-uddyn).—This is the first instance that we have known of a silvered-powdered Gymnogramma having both silver and gold powder on the under side of the pinnæ. What makes it more remarkable is that some pinnæ should be wholly golden-powdered. It is likely you would obtain a golden Calomelanos by sowing the spores of the pinnæ of that colour, and no doubt many silver ones.

REPLANTING BOX EDGING (Thomas Marsh).—You may now take up and replant the Box as you propose. There is no fear of its not growing, providing you use rooted divisions or slips, and water at planting if the ground be dry. If the weather be moist the watering will, of course, not be necessary. You may remove the very straggling growths, but that should be done at the trimming before planting, and no after-cutting with the shears is needed, or, if there be, the edging is badly planted. It will grow quite as well now as planted in February.

REPLANTING TULIPS (Idem).—You may now take up the Tulips that have remained in the ground all the year, removing them with a ball if they have rooted, and replant at once; or during the time they are out of the ground they should be carefully shielded from the sun and wind. We cannot answer questions privately.

DESTROYING HORNETS' NEST (Subscriber).—The best plan would be to dip some strips of paper in melted stone brimstone, set light to them,

and place them in the hollow in the old Apple tree, closing the hole so as to confine the fumes. This, of course, will need to be done after twilight. You must close every hole, or, if that be impracticable, pour in some spirits of turpentine, and close the opening.

KING OF THE FUCHSIAS (J. G.).—It is not a free-blooming sort, but does not require treatment different from that of other kinds. Why grow it in the stove? A light airy greenhouse, with a slight shade from very bright sun, is the best place for it.

TENANT REMOVING (W. B. B.).—If you pull up, cut down, or otherwise injure any of the trees or shrubs, planted either by your father or yourself, you will act illegally. You are not a nurseryman. Your landlord cannot be made to pay for the trees and shrubs. You have no right to remove the flagstone if fixed to the walls. You may remove the Cucumber frames. You must consult your solicitor on the other questions.

PAINTING A PEACH HOUSE (J. X.).—There is no objection to green paint in point of colour for the outside woodwork of a Peach house, but it is not durable. That paint is found to answer best which is composed of the most lead; hence white paint is the best of all next to red (which is a very objectionable colour); but we think a pale stone colour preferable, as it does not show dirt so soon as white. That kind of glass known as crown, having a green hue, is preferable to the white sheet; but we are using 26-oz. sheet glass for the roofs of Peach houses, and glazing the fronts with $\frac{1}{4}$ -inch polished plate glass. For a fernery we are using $\frac{1}{2}$ -inch rough plate; whilst for a stove we have $\frac{1}{2}$ -inch rough plate ground on one side for the roof, and glaze the sides and ends with $\frac{1}{4}$ -inch polished plate. A ray of light is of three colours.

EARLY PEACH TREES (Amateur S.).—Your espaliers are no doubt in an orchard or other house, for in the open air we think the espalier a very uncertain means of growing Peach trees. Two of the earliest early Peaches are Early Beatrice and Early Rivers, both good, and to succeed them you may have Early York. They ought not to be removed until the leaves have begun to fall.

INDIAN SHOT (CANNA) TREATMENT (Idem).—The varieties of *Canna* are much employed for subtropical gardening. You do not say whether your plant is in a pot or planted out, but we presume it is a pot plant. In that case you will need to continue it in a greenhouse during the winter, watering up to December, but not excessively. If the foliage be kept fresh, that is sufficient. Until the middle of February keep the plant dry, then repot it, and encourage growth by an increase of moisture and warmth, and, if possible, with bottom heat. If wanted for planting out of doors in summer, harden the plant well off before turning it out at the end of May or beginning of June.

BOXES FOR HOLDING USEFUL MEASURES.—We have to warn our readers that the quotation we made at page 184 from the "English Mechanic," does not give correct dimensions. The Editor of that journal has since published the following:—"We obtained the above-mentioned paragraph from a journal called the 'American Artisan.' As it appeared to contain what is simply a matter of calculation, it did not undergo the usual editorial criticism. In future we shall hesitate before we insert any valuable tables found in our transatlantic contemporaries." We are obliged to a correspondent, "A. L.," for bringing the above to our notice. He adds:—"Subscribers will do well, therefore, to put a note of warning against reliance upon it in the margin of their copies. I give an instance of error. A pint really contains 34.659 cubic inches, plus a very small quantity, which may be disregarded. The table states that a box of 4 by 4 by $\frac{1}{2}$ " = 68 cubic inches, will contain a pint. So it will, and nearly another pint."

DESTROYING WOODLICE (L. E. G.).—The best plan of destroying them is to place a little hay loosely round the sides of the structures they infest, and in the morning pour boiling water down the walls a little above the hay. This, of course, kills all it touches, and repeated several times will entirely destroy them, though they will in time reappear. When this method cannot be adopted on account of the boiling water being likely to injure plants, your best plan will be to place a boiled Potato wrapped lightly in a little hay in a small flower-pot, and put the pot on its side where the woodlice are troublesome. This trap should be examined every morning, and the woodlice secreted in the hay shaken into boiling water. A number of traps of this kind, put down every night and examined in the morning, will soon thin their numbers.

PETUNIA SHOOTS DYING (Idem).—We cannot account for your Petunia dying back, but think it is owing to the flowering shoots being broken off. The plant will probably die back to the shoots at its base, to which we should cut down.

RABBITS ATTACKING WELLINGTONIA GIGANTEA (T. Wilson).—Although the Wellingtonia is not so much destroyed as many other trees by rabbits still it is subject to their attacks, and we have seen every twig, leader and all, eaten off a number of very promising young trees, the bark being also nibbled off, but the spongy bark of older trees they do not meddle with. Where rabbits and hares are numerous, we would not advise you to leave your specimen trees unprotected. We think a piece of galvanised wire-netting, 2 feet or 2 $\frac{1}{2}$ feet high, fixed to the inner side of the iron fence which protects the trees from the cattle, will be all that is wanted. This would admit air to the lower branches, and be altogether better than woodwork. The netting must be sunk an inch or two into the ground; or, what is better, if a board be first sunk in the ground, the edging of the netting might be fixed to it; but we do not recommend any deep digging near the Wellingtonia, as its roots are so near the surface. Be satisfied with merely inserting the netting an inch or two, and examine it occasionally in order to stop any attempts at burrowing under it. We are glad to hear you have so fine a tree so far north; it is well worth taking care of. It is unaccountable, but nevertheless true, that rabbits have a propensity to attack choice single specimens; where there are a number of plants of one kind the probability is they will all escape, whilst a single tree is sure to become a prey. In our own case we find nothing escapes their attacks excepting, perhaps, the common Elder, Box, and Rhododendron ponticum, and even the last-named is not always safe.

TORTOISE (Notice).—We are not aware that tortoises benefit a garden. They live upon Lettuce leaves, Sow-thistle, and other succulent vegetable produce. They should be taken in-doors during the winter, unless there are large heaps of leaves in which they can bury, for they are torpid throughout the winter.

PLANTING AN AVENUE (Violet).—Without knowing more of the size of the avenue, we could say little as to grouping it prettily. In an exposed

bleak place, Pinus Pinaster and austriaca would do well; and Deodars and Wellingtonias might be tried, but neither should be planted thickly. We have seen fine effects made in the sides of avenues, where, as in your case, Rhododendrons would not grow, by planting such Pines about 35 feet apart, and then clothing the ground with a carpet of Laurels kept cut every year.

LIST OF ROSES (M. B.).—I am asked to name twenty-four Roses "the best for exhibition in all colours, and that are hardy and free bloomers." I could diversify the colours more if I were allowed to name some Tea Roses; but as nothing is said about them, I shall only name one, Sombreuil, white, which is very hardy, a free and constant bloomer. Then have Charles Lefebvre, Marechal Niel, Senateur Vaisse, Souvenir de la Malmaison, Comtesse Océide de Chabrilant, La Ville de St. Denis, Pierre Notting, Alfred Colomb, Madame La Baronne de Rothschild, Madame Victor Verdier, Triumphe de Rennes, Madame Boll, Prince Camille de Rohan, Coline Forestier, Dr. Andry, Marguerite de St. Amand, Gloire de Dijon, Lady Suffolk, Marechal Vaillant, Madame Boutin, Jules Margottin, William Griffiths, John Hopper, and Mademoiselle Marie Raby. I add a surplus of good Roses—Gloire de Vitry, Duchesse de Cuyllus, Baron Gonnella, Lord Clyde, Leopold Premier, and Baron Adolphe de Rothschild. I name some of the best Tea Roses in delicate colours—Devoniensis, Souvenir d'Elise, Souvenir d'un Ami, Madame Willermoz, Madame Margottin, and Adam. The new Tea Rose, Marie Sisley, has just bloomed well, and is extra fine. The plant is small, and I can say nothing of its growth. Marechal Niel must have a wall. My best plants are on the front wall of my vineery. They are on the Manetti stock, and grow and bloom well. The best plant of it that I ever saw is on a low Briar on a vineery wall out of doors, at Mrs. Oliver's, at Child Okford. The blooms grown there were by far the finest that I ever saw—like large bells. It is a famous Rose for a hot town garden. If it is objected to, select Duchesse d'Orleans for light colour, or Lord Clyde for deep colour. All the Roses named are here on the Manetti, and do well. It is right to say, that although Alfred Colomb is one of the fullest and finest of the show Roses, it does not always in the fore part of the season bloom freely.—W. F. RADCLIFFE.

IVY-LEAVED GERANIUM (W. M.).—Your specimen is not one of the Ivy-leaved varieties.

GRAPES (W. G.).—The small Grape is the Royal Muscadine. The other we do not recognise; it is certainly not a Muscat. Send another bunch with one or two leaves.

MELON DE NAMUR PEAR (G. B.).—We do not know it.

PEARS FRUITING IRREGULARLY (C. W. H.).—Being able to secure blossom regularly throughout, one would suppose there should be fruit also. We believe your trees fail to fruit, excepting at the extremities of the branches, from a want of equalisation of forces. Better fruit spurs are produced at the points of the shoots, perhaps through their being better exposed, and thus better matured, &c. Young trees frequently bear only partially; when, however, they have filled their allotted space, and by carefully summer-pruning the young shoots the active forces of the tree are equally distributed throughout, you will find fruit produced quite regularly all over. Bending down the branches as you propose, we do not think would be of much service. We attach far more importance to the summer pinching and regulation of the leaves or lungs of the tree.

STORING FRUIT (R. J. S.).—The conditions most conducive for the preservation of fruit are a dry atmosphere and a cool equal temperature with darkness. Light hastens decay; so does a close, warm, damp atmosphere. It is well, then, to keep your fruit-room tolerably dark, cool, and airy. We would not be at the trouble, however, to barricade the windows to any inconvenient extent. We do not know where you can obtain a fountain like that referred to. The design was American.

GARDEN LOSSES IN FRANCE BY THE WAR (Edm.).—We have no statistical information on this subject, but we see that it is stated in the *Journal de l'Agriculture*, that the French farmers have lost more than £163,000,000. We deplore as much as you do the unnecessary and terrible contest, but our columns must not be opened to the subject. There would be no wars if the only gladiators were allowed to be monarchs and their ministers.

"O, if I were King of France,

Or, what's better, Pope of Rome,

There would be no fighting men abroad

Nor weeping maids at home.

All the world should be at peace,

Or, if kings must show their might,

I'd let those who make the quarrels

Be the only ones to fight."

SELECT CLEMATISSES (Q. Q.).—C. Jackmanni, which you know, is one of the best, and another of Mr. Jackman's raising—viz., Beauty of Surrey, pale blue, with smooth and stout petals, is fine. Lady Londesborough, raised by Mr. Noble, Bagshot, with pale lilac flowers, is large and showy, and so is Miss Bateman, white. These are four fine Clematises, but we do not think they would do for trellises in an exposed situation on a hill top. If planted against a trellis this autumn they would not require pruning next spring, nor would they flower to any great extent next season. A good rich light loam is the best for them. Probably the finest of the Clematises is Excelsior, double, bluish mauve, with a flame of brown along each petal; stamens white. To do well in cold situations they require an aspect between south-east and south-west. Where they require protection in winter they will do little good in summer, but for young plants a slight protection is good early in spring.

SPANISH AND ENGLISH IRISES (Idem).—Let them remain in the ground, and mulch it with well-rotted manure or leaf soil. From one year's growth they will not have spread so much as to need taking up and dividing; we like good clumps of them, not stragglers. To be seen to advantage, a mass is best.

SIRKIM RHODODENDRONS REPOTTING (An Old Subscriber).—The best time to repot them is in spring, just before they begin to grow. We would not cut in the plant of Dalhousie until spring, and then do not repot until it has made fresh growths 3 or 4 inches long.

LILIUM ACERATUM AND LANCEIFOLIUM TREATMENT (Idem).—Pot them now. Turn them out of the pots, remove the drainage, all the old soil that comes away freely, and all the offsets not of a flowering size. Pot the bulbs in well-drained pots, using a compost of one-half light turfy loam, one-fourth old cow dung or leaf soil, and one-fourth sandy fibrous peat, with a free admixture of sharp sand. Allow the roots a moderate

amount of pot-room, and pot so that the crowns may be barely covered with soil. Allow for about an inch of top-dressing to be applied in spring when the shoots are about 6 inches high, doubling the quantity of cow dung along with the loam and peat named for potting in. Winter the bulbs in a cold frame, protecting them from frost. They will need but little water during the winter; merely keep the soil moist. When they are growing freely water copiously, but avoid saturating and souring the soil by frequent heavy waterings; and if you can afford a cold pit or other cool place, with plenty of light and air, they will grow strongly and flower finely. The main point is to give encouragement when they are starting and up to full growth, and do not disturb the roots by frequent and needless repotting and shifting. Keep the plants free from insects.

EDGING TILES (A. W.).—There are no better tiles for edgings to walks or borders than those made of fire clay. You may obtain particulars from those who advertise in our pages.

TRANSPLANTING EVERGREENS (S. H. S.).—When removed there ought to be good balls with all evergreens of considerable size. We would advise planting now, only the ground is so very dry that it would be difficult to take the plants up with a ball, and they would need to be well watered after planting. If you have rain with a ball, that is quite as good as digging round each plant and leaving it a year. No good is done by digging round the plants in autumn, and then waiting until spring in the hope of a ball, for at that time they will be in little or no better state than when they were dug round. A year is necessary to secure roots near the stem. If you do not remove them this autumn, do not remove them before March. Early in autumn and late in spring are the best times for transplanting evergreens; the autumn is to be preferred if the weather is moist and mild.

VARIOUS (Idem).—It is not too late to put in cuttings in boxes, placing them out of doors in a warm situation, but protect them from frost, and house them early in November. The proper time to put in cuttings of *Calceolarias* is from the present time until frost occur, inserting them in a cold frame in a dry, sheltered situation, having about 6 inches of soil, and over that an inch of sand. The cuttings may be put in about 14 inch apart, and should have a good watering; afterwards they need abundance of air and protection from frost. There are two ways of forcing *Rhubarb*, one by placing boxes or pots over the crowns, so as to enclose them, and then covering up with stable litter in a high state of fermentation, to cause the speedy growth of the *Rhubarb*. The other plan is to take up the roots and place them in a house or shed having a temperature of 50° to 60°, just covering them with soil. You may practise either of the modes named from the middle of November to March. *Salvia patens* is freely propagated by divisions of the roots; but both cuttings and seeds answer very well. The insect on your *Fernis* is not a thrips, but a male aphid; both are destroyed by fumigation with tobacco. The insect is probably brown scale. The best remedy is to cut off the fronds most infested and burn them, and to pick off the soft insects with the point of a knife—a tedious but safe mode of clearance. Insect-destroying compounds will also rid you of them. The best way to utilise a piece of ground for growing vegetables for a family, is to trench and manure it well, and plant it with the kinds of vegetables required. The piece of ground is so small, that it could hardly be wrongly planted with a vegetable liked by the family: Potatoes or Cabbages for instance. The fumigating of the conservatory with tobacco will not injure the fish in the aquarium, but with sulphur you would not only kill the plants, but jeopardise the fish.

SNAGS ON FRUIT TREES AND LIST (In Amateur).—The espalier Pear and Plum trees kept closely pinched through the summer should not have the snags cut off until the leaves fall, and then you may cut each shoot to within an inch of its base, or, if there are spurs, down to them. The pyramid Apple, Pear, and Plum trees planted in ground deficient of vegetable matter, would not be improved by a dressing of lime, though it would do no harm. Chalk would be better, covering the ground an inch deep with pieces between the size of walnuts and hens' eggs, and then mix it with the soil as well as you can. If your soil is light a good dressing of marl would be better. The most profitable Apples and Pears to be trained as oblique cordons on a wall having an east aspect but exposed to the north, would be—Apples: Red Astrachan, Summer Golden Pippin, Margil, King of the Pippins, Sam Young, Golden Pippin, Scarlet Nonpareil, Braddick's Nonpareil, Cockle Pippin, Sykehouse Russet, Court of Wick, Calville Blanche, Kedleston Pippin, Mannington's Pearmain, White Nonpareil, and Sturmer Pippin; kitchen Apples, Lord Suffolk, Nonsuch, Gravenstein, Dumelow's Seedling, Bedfordshire Foundling, Bess Pool, Striped Beefing, Rymer, and Northern Greening. Pears: Beurre Giffard, Bea Chrétien, Beurre d'Amanlis, Louise Bonne de Jersey, Conte de Lamy, Baronne de Mello, Beurre Clairgean, Beurre Diel, Dr. Trousean, Thompson's, Alexandre Lambré, Beurre d'Arenberg, Alexandre Bivort, and Zéphirin Grégoire.

FOSTER'S BOILER (T. Cor).—We sent your letter to Mr. Pearson, and the following is his reply:—"I have two of the boilers at work, and intend to have another, as they are all that I stated. Unless Mr. Cox's boiler is under the house itself, it is not likely to work if uncovered with brickwork, except at a great disadvantage. The smoke ought to be carried round, and over the outside, as in a saddle boiler. It will also act better with coal than with coke. If well set I am sure there is no boiler equal to it, unless he has one of too small a size. Mr. Foster made some little ones I never did like. Mine cost £19, and they are all I could wish.—J. R. PEARSON."

MELONS (Q. Q.).—Meredit's Hybrid Cashmere is a good fruit, not large, as you say, but with two fruit or so on a plant it attains a good size. It is to some extent a continuous bearer, the plant, unlike many other varieties, growing when the fruit is swelling. However, some persons like Melons to be small and rich; others care not how large they are, nor how much sugar is required to make them palatable. Heckfield Green-flesh or Hybrid is an excellent sort, little, if at all, different from Meredit's; but whether the one or the other be grown, with fair cultivation a good crop of Melons, good in appearance and quality, will result. If anything, the Heckfield has the better constitution.

SMALL GREENHOUSE (B. S.).—We approve of all you have done and propose doing, except adding a fourth of leaves and rotten vegetables to your Vina border. Instead, we would use two-thirds of the marly and sandy fresh loam, and one-third of equal parts of boiled bones, old

mortar rubbish, charcoal free of dust, and the pigeon dung well exposed to the air. We would add no other animal manure, but you may mulch the border with horse droppings. You had better have two or three squares of glass to open at the apex of the roof, in addition to those at the end, or have the proposed openings at the top of the wall. We would plant Barrington Peach, Moorpark Apricot, and two Black Hamburgs for one house, and Black Espérance or Royal Muscadine for the other. Plant the Vines as soon as you like, the others by the end of October. Protect the Vine border after planting.

FLUE-HEATING (W. E. C.).—In such a case as yours, the flue would do very well, but for a couple of yards after entering the house we would make it brick-on-bed, and cover with strong tiles. In a close chamber beneath your Cucumber-bed, strong slate would be the best covering, and that about 4 inches from the top of the flue. On the slate place 2 or 3 inches of drainage below the soil, and an inch above the slate have two or three upright drain-pipes, by pouring water down which you will obtain a moist heat from the slate, either for bottom heat by plugs, or top moist heat by opening the plugs. If economy is your object, a wall bounding your chamber, we would fill-in all round your flue and for 4 inches over it with flints, brickbats, &c. piled as open and as loosely as possible, and then finish with an inch or two of concrete for the soil to lie on, having previously fixed a few upright drain-pipes amongst the rubble, for the purpose stated above, avoiding pouring water at any time directly on the flue. In your proposed quite open chamber, and in this rough open one of brickbats, &c., it would be well to have openings to let out heat to the atmosphere when wanted in a cold day or night. By cementing the bottom of your bed you can always clear out the soil without any trouble. You could place evaporating pans on the end and back flue where open and exposed. We think the flue would be ample for the place, but if you have the small boiler and pipes doing nothing, you might fix the boiler over the fireplace. Such a boiler so placed might heat another small house.

HEATING A PIT IN SEPARATE PARTS (Fior).—You can carry out the desired arrangement on your proposed plan by having a valve on your flow-pipe as it passes into No. 2 pit, and though not absolutely required, it would be as well if you had one on the return-pipe likewise. This is all very well having the boiler at one end, and as you wish the place next the boiler to be generally heated; but you cannot heat the further pit without heating the nearer. If you had placed the boiler where the two pits or houses meet, and taken a T down and return from it with a valve on each, you could heat either part separately just as you liked. You could do the same thing without valves, in the way you allude to, by taking the flow-pipe from the boiler into a cistern—say 12 inches square by 12 deep, and placed some 12 or 18 inches above the flow-pipes in the houses. From that cistern take a flow-pipe for each house, and have plugs to fit them, and shut or open as you like.

BOILER FOR SMALL GREENHOUSE (A. B.).—A very small common saddle-back boiler, exposing 2 square feet of surface to the fire will be best. Any of the boiler-makers who advertise in our columns can supply you.

HEATING FROM HOUSE BOILER (W. S.).—The height of the greenhouse floor above the kitchen floor is of little consequence. The great point is to have the pipes in the greenhouse higher than the top of the boiler. A flow pipe taken from that which goes to the top of the house would go to the greenhouse on the right level—that is, rising a little. The valve at A would be useful in directing the flow horizontally instead of vertically, and might be opened as soon as the flow took place. On that down pipe to the greenhouse you must place your valve or stop-cock. It would be of little or no use as you show it on the return pipe at F. There would be a little risk of a careless person leaving the valve on the vertical pipe shut. To prevent any unpleasant contingency, and as there seems to be a little distance from the boiler to the greenhouse, we would cut out an opening in the top of the boiler to screw in a 1-inch strong gas pipe, make that the flow to the greenhouse, and have a return of the same size screwed into the present return pipe to the boiler. These could be packed in a box of sawdust. Let them be joined with cup ends to 3-inch pipes in the greenhouse, two of which would keep out frost, but three the length of the house would make all more safe. Even then it would be well to have the pipes in the greenhouse rising to the further end, say 3 or 4 inches, and at that end fix the smallest gas pipe, taking it up as high outside the house as the height of your hot-water cistern. We are thus particular because, though we have seen different levels heated horizontally from one vertical pipe, the heated water has such a tendency to rise, that the lowest levels have the most sluggish circulation.

NAMES OF FRUIT (J. B.).—Brown Turkey Fig. (A. H.).—If the flowers are small and of a deep red colour, we should say it is Red Roman Nectarine, a clingstone variety unworthy of cultivation. (Harrison Weir).—We cannot recognise the variety. (H. M. G.).—Pears: 1, Flemish Beauty; 3, Navez Peintre; 5, Beurre d'Amanlis; 7, Pomme Poire (Apple); 8, Seckle. Apple: 1, Broad-eyed Pippin. Your examples are so small and scrubby, possessing no characteristic features, that it is next to impossible to recognise them. (J. F. Lombard).—Pears: 1, very beautiful fruit, which we do not recognise; under what circumstances was it grown? 2, Althorp Crassane; 3, Doyenné Blanc; 7, Fondante d'Automete; others not known. (J. W. Laurie).—Apple not received. Pears: 1, Easter Beurre; 2, Black Achan. (J. P.).—Apples: 2, King of the Pippins; 3, Brabant Bellefen; 6, Rymer; 8, Dumelow's Seedling. Pears: 4, Beurre de Rance; 7, Haecon's Incomparable; 9, Easter Beurre; 1, Beurre Bosc. (Scyber).—Pears: 1, Beurre d'Amanlis; 2, Althorp Crassane; 3, Marie Louise.

NAMES OF PLANTS (M. R.).—1, *Platyloma falcata*; 2, *Pteris cretica*; 3, *Doodia caudata*; 4, *Polypodium loricum*; 5, *Davallia bullata*. (A. Constant Reader).—1, *Origanum*; *Tonrefortii*; 2, *Pentstemon gentianoides*; *Crataegus*, name next week. The Fern was *Asplenium Ruta-muraria*: by us. (A. Lancashire Lad).—The Fern was *Asplenium Ruta-muraria*: quite true. The scrap of plant sent was not that of the true Pepper plant, but of a shrub, *Schinus Mollis*, the leaves of which have a warm peppery taste, so giving rise to the name. (Memorandum).—1, *Miranda hians*; 2, *Bihisus Rosa-stansis fl.-pl.*; 3, *Begonia xanthina amorea*; 4, *Liaaria Cymbalaria*; 5, *Calathea bicolor*; 6, *Aspidistra lurida variegata*. (M. H.).—1, We do not recognise this Composite at present; 2, *Euphatorium salicifolium*. (Subscriber No. 38.).—*Muhlenbeckia complexa*. (James Carter, Ifford).—Both are *Enothera missouriensis*. (A. Sayer).—Sweet Scabiosa, *Scabiosa atropurpurea*.

POULTRY, BEE, AND PIGEON CHRONICLE.

THE BIRMINGHAM SHOW OF 1870.

An examination of the Birmingham schedule for this year does not reveal any marked novelties as on former occasions. The Council apparently consider that they have now arrived nearly at perfection, and that their long experience and reflection have at length resulted in the "very height of acme," beyond which poultry schedules can no further go: hence their programme is in most particulars similar to that of last year. I confess I think the Council are mistaken. Many and great are the real improvements they have introduced into poultry exhibitions, most of which have been approved and copied by all others of any standing; but it seems to me the show is yet trammelled and injuriously affected by the set traditions of other days. I give my difference of judgment in all humility, but it is the result of several years' observation, and has been confirmed by most of those to whom I have spoken on the subject. The one great fault universally remarked of the Birmingham Show is the immense number of inferior specimens, which make the exhibition unwholly, and render an inspection of it physically exhausting. It is understood that the subject last year engaged the attention of the authorities, and the remedy they devised was to raise the entry fees by the amount of *sixpence*! It need hardly be said that the result, though in the right direction, was not appreciable; and I am more and more convinced that the radical root of the evil is the antiquated sovereign subscription (a system exploded everywhere else), which groups most of the entries into clusters of four pens. The effect is that every exhibitor makes up his four entries if possible, and in order to do so sends often inferior birds merely for sale; whilst, on the other hand, to my personal knowledge, individuals who have possessed a single pen only, which would have been a real attraction to the show, have been deterred from sending by the knowledge that the venture would cost them 23s. The problem is to get as many good pens as possible, and to weed out the bad ones, without pecuniary loss: and I feel convinced, as do most to whom I have mentioned the matter, that to abolish subscriptions altogether, to give each exhibitor only one admission ticket (as at present the tickets are given away wholesale), and to charge, say, 12s. for a single, and 7s. 6d. for every subsequent entry, would to a great extent accomplish all these objects, and raise the tone of the show materially. Perhaps, indeed, it would then be too perfect, and those who had been so long connected with it would have to follow the example of the celebrated mechanic who spent all the ingenuity of his life upon a garden engine, and then died just as he had finished polishing the handle. Nevertheless I make the suggestion, and perhaps it may be found worth considering.

Regarding details, as already said, there is little this year to remark. In most of the leading varieties there are cups and five other prizes for the cockerel and pullet classes, with three prizes for each class of old birds. In Buff Cochins, however, owing to the liberality of amateurs, there are cups and four other prizes for the old birds, and I expect the result will be such an array of Buffs as even Birmingham can rarely boast. I fear our Light Brahma friends will be really savage, this variety being cut down to three prizes each for the old classes, and four each for the chickens. The simple truth is, it is useless for anybody to talk as if such and such prizes were "due" to any variety whatever. The only way to get good prizes is to fill large classes; and the fact is that where the prizes are equal, on an average the Dark entries are about double the Light. It is no fault of the breed; but an examination of any catalogue will show that town amateurs form a very large portion of poultry fanciers; and as no very light fowls can be kept in a town to be shown with credit, the classes will always be smaller. Take White Cochins, White Dorkings, or White Bantams—the result is always the same, and for the same obvious reason.

By the liberality of amateurs, again, there are this year four classes of Malays, of two prizes each. This will rejoice the heart of "Y. B. A. Z.;" and as there are thus eight prizes I hope on this occasion there will be rather over eight pens, if it be only for the look of the thing, and to keep each other in countenance. I cannot help thinking this breed is deteriorating very much in size as well as in numbers. It used to be a large variety, now I rarely see a Malay cock without thinking of "the tall thin gentleman with the shiny boots on."

The great blot of the schedule is the fact of there being only one class, of three prizes, for "any other variety," cock and hen having to be shown together. Every show in the kingdom, almost, gives more than this; and when we consider that Andalusians, Minorcas, Laghorns (which are now beginning to be known in England), Sultans, Silkies, Japanese, Black and Cuckoo Cochins, Guinea Fowls, and many other varieties have no other place of refuge, I cannot help thinking that the printer's imp must have feloniously abstracted three or four lines of type from the sheet before it was printed.

In the other poultry classes it is worth remark that Aylesbury Ducks have only four prizes, while Rouens have six. Time was when it was all the other way; but the Rouens first challenged, then equalled, then passed their rivals, not only in number but in weight, and the prizes now adopted may be considered to settle the point that they have now decisively won the first place, both in popularity and utility. The fact is another illustration of the argument above regarding white fowls.

In Pigeons, six classes for Carriers, and no less than ten for Pouters ought to bring a magnificent array for competition. A five-guinea cup for Blue or Silver Runts, given by Mr. T. D. Green, is rather a novelty in a Pigeon show, and I shall expect to see some big birds. A cup and four classes for Antwerps show the rapidly increasing enthusiasm in favour of this symmetrical and intelligent variety. The other classes are almost precisely the same as formerly.

In conclusion, let me express a hope that the Council will again secure a copy of the magnificent poster relating to the New York Show, which attracted so much attention last year.—L. WRIGHT.

CLASSES FOR WHITE BANTAMS.

A CORRESPONDENT signing himself "WHITE BANTAM," asks for separate classes for that variety. The truth is, White Bantams are becoming so scarce, that when they have separate classes there are never sufficient entries to pay the prize money. This has been the result at the Bristol and Clifton Show, and it is the intention of the Committee to strike out the class. At the last exhibition there were only five pens entered to compete for three prizes, respectively £3, £1 10s., and 15s. If "WHITE BANTAM" will communicate with me at once, I will endeavour to have the class retained in our next prize list, which will be shortly issued. At the same time I would be glad to hear from any amateur who will raise subscriptions for special cups for any particular variety of poultry or Pigeons at our next Show. The Committee will be glad of any such assistance.—E. CAMBRIDGE, *Cotham Brow, Bristol.*

DERIVATION OF CRÈVE-CŒUR.

In your answers to correspondents you seem to imply that the name of this breed is derived from the form of the crest, as a cloven heart. You must allow me to differ from this. There is a town in Normandy of that name, and it is from thence, as in the case of the Dorking, that the name is taken. I should add that the Caumont, Houdan, and Gournay fowls are, in the opinion of M. Jacques, "veritables ramifications du Crève-Cœur." I can bear testimony to the valuable properties of this handsome breed. They lay a large number of very fine eggs, and keep on laying through their moulting time. I have some now running under bare poles, ragged-looking creatures, yet laying every day, or nearly so.—D., *Deal.*

ORNITHOLOGICAL SOCIETIES' SHOWS—PRIZE LISTS.

I AM glad to find that such societies are increasing; but I should like to draw the attention of the secretaries and committees to the desirability of having some person appointed to unpack all specimens sent by exhibitors as soon as possible after their arrival, and to give food and water to all of them, as they suffer much from thirst, especially Pigeons, when they have to travel a long distance. I hope the Sheffield Committee will set an example to other exhibitions, and also be well supported, as some of the prizes are greatly in advance of previous shows at other places, those for the Rabbits and cage birds especially.—BIRD FANCIER.

THE SOUTHAMPTON POULTRY SHOW.—In the schedule we notice a very marked improvement upon that of former years.

as at this Show two years ago, when both the Patagonian of 14 lbs. weight, and the Belgian Hare Rabbit of 9 or 10 lbs., were sent for competition. May I suggest to exhibitors the desirability of their not speaking to or interfering with the Judge when in the discharge of his duty? To say the least of it, it does not look well, and I hope this hint will be sufficient.—C. R.

STOKESLEY AGRICULTURAL SOCIETY'S POULTRY SHOW.

On the 22nd the Stokesley Show was held. The poultry were well shown in wire pens under cover, and the entries in most of the classes were large. *Dorkings* were few in number and not good. *Spanish* were also not good, with the exception of the hen in the second-prize pen. *Game* were large classes and in fine form. Mr. Blackburn's second-prize cockerel, although undubbed, was a most remarkable bird and will be heard of again. In *Hamburgs* the mistake was made of showing Pencilled and Spangled birds together. If committees cannot afford to have four classes they should put all the Pencilled together and all the Spangled together. There were fifteen entries, and not a good pen. Adult *Brahmas* were of very moderate quality, but the chickens were not far from the mark. The *Variety* class was very strong—thirteen entries. The first prize was given to a first-rate pair of Light *Brahmas*; here a mistake was made, for there being a class for Brahma chickens they should not have been allowed in this class. The second prize was given to the best pair of Golden Poland chickens we have seen this season. There were also Houdans, Crève-Cœurs, Spanish, and Black Polands noticed by the Judge. Among *Ducks*, except the first-prize pens, there was nothing worthy of notice; but the locality has been long celebrated for its Geese and Turkeys, supplying all our noted exhibitors with their prize birds, and on this occasion it surpassed itself. There was so little difference in the *Geese* that the whole were weighed, when the scales showed a difference of 2 lbs. Whites were first in both classes; the second prize in the adult class also went to Whites, Greys only coming in second. In the young class *Turkeys* could not be surpassed at any show.

Pigeons formed a very fine collection. The first-prize Fantails well deserved their position, as did the Jacobins. In the "Variety class" a very good pen of Magpies was first, Black Trumpeters being second.

In the one class for *Rabbits* there were nine pens, consisting of Himalayans, Angoras, and Lops, among which were some very fine Rabbits.

SPANISH.—1, J. Fuller, Yarm. 2, Miss Flintoff, Newby. DORKINGS.—1, E. Barker, Stokesley. 2, Mrs. Storey, Stokesley. *Cock*.—1, Rev. J. E. Newton. 2, E. Barker. *Chickens*.—1, E. Barker. 2, Rev. J. P. Newby. *Game*.—*Willow-legged*.—1 and c, T. Blackburn, jun., Great Broughton. 2, W. Gattenby. *Yellow-legged*.—1, Lox, Stokesley. 2, Withheld. *Cock*.—1, M. Peiron, Great Aylton. 2, T. Blackburn, jun. *Chickens*.—1 and c, T. Blackburn, jun. 2, W. Gattenby. *HAMBURGS*.—*Silver-pencilled or Spangled*.—1, W. Dale, Danby, Yarm. 2, H. Garbutt, Yarm. *Golden-pencilled or Spangled*.—1, G. Garbutt, Yarm. (Poland) c, Lady D. Yeoman, Whiby (2); J. Fuller; G. Seely. *BANTAMS*.—1 and c, E. Barker, Stokesley. 2, T. Blackburn, jun. *DUCKS*.—*Any Breed*.—1, Mrs. Fidler (Aylesbury). 2, J. Mitchell, Castleton (Rouen). *Ducklings*.—1, Mrs. Storey, Stokesley. 2, Mrs. Jackson (Aylesbury). *GEESE*.—1, Mrs. Storey (White). 2, Mrs. Braithwaite, Stokesley (White). *GOSLINGS*.—1, Mrs. Storey (White). 2, Mrs. Hindson (Grey). c, Mrs. Braithwaite (White); Mrs. Storey (White). *TURKEYS*.—1, Mrs. Braithwaite. 2, W. R. L. Hopkins, *Poult*.—1, Mrs. W. Ward, Bannid Flat, Whiby. 2, H. Elthf, Seamer. *he* and c, Mrs. Storey.

PIGEONS.

FANTAILS.—1 and 2, T. C. Taylor, Middlebrough. *POUTERS*.—1 and 2, T. C. Taylor. *CARRIERS*.—1 and 2, T. C. Taylor. *JACOBINS*.—1, R. Pearson, Danby. 2, W. Dale. c, J. Garbutt, Farncliffe. *TOMBERS*.—1, T. Robinson, Fryup Head, Castleton. 2, J. Garbutt, c, W. Rudsdale; T. C. Taylor; W. Carter, Staunton. *ANY OTHER VARIETY*.—1, W. Dale. 2, W. R. L. Hopkins. *Poult*.—c, W. Rudsdale; W. O. Garbutt (Barbs and Tarbits).

RABBITS.—*Fancy*.—1, W. Cross, Raswarp Hill, Whiby (Black and Dun) 2, J. T. Ranson, Stokesley (Himalayan). *he*, G. Skeen, Stokesley (Himalayan). c, W. Carter, Staunton.

Mr. Samuel Barn, Whiby, was the Judge.

WETHERBY POULTRY SHOW.

The Show was held on the 23rd inst., and was a complete success. *Geese* came first in the list. Both the winning pens were Toulouse of great size and weight. The *Aylesbury Ducks* were good in beak and plumage, likewise the ducklings. There was but one pen of *Turkeys* of the Cambridge variety, but they were very fine. *Cochins* were poor, but the *Spanish* were very good, notably the chickens. The most striking pens of all were those of the *Dorking* chickens, which were of extraordinary size. The *Game* were good in both classes, but with the exception of the Silver-pencilled birds the *Hamburgs* were poor. The first prize in the "Variety class" was taken by Brahma chickens of great merit, and some of the *Bantams* were very good, although the *Game* were rather late in feather. There were also a few *Pigeons* and *Rabbits* in the class for extra stock.

GEESE.—1, O. A. Young, Driffield. 2, J. Simpson, Spofforth. *he*, T. Ripley; W. Wheelhouse, Linton. *DUCKS*.—1, O. A. Young. 2, H. S. Thompson. *Ducklings*.—1 and 2, O. A. Young. *he*, H. S. Thompson. *TURKEYS*.—1, Mrs. Gunter. *GUINEA FOWLS*.—1, O. A. Young. *COCHIN-CHINAS*.—1, Messrs. Pickard, Thorner. 2, R. R. Farrer, Green Hamerton. *Chickens*.—1, O. A. Young. *SPANISH* (Black).—1, Messrs. Pickard. 2, O. A. Young. *Chickens*.—1, Messrs. Pickard. 2, T. Beaumont. *he*, J. Foot, Boakings. 1, Mrs. Gunter. *Chickens*.—1 and 2, T. E. Kell, Wetherby. *he*, R. R. Farrer. *GAME*.—1 and 2, J. Watson. *he*, T.

Hawkes, Hunsingore. *Chickens*.—1, J. Watson. 2, J. Robshaw, Whixley. *he*, R. R. Farrer. *POLANDS*.—1, Messrs. Pickard. *HAMBURGS*—*Golden*.—1, G. Allen, Collingham. *Chickens*.—1, O. A. Young. *Silver*.—1, H. S. Thompson. *Chickens*.—1, J. Watson. 2, O. A. Young. *CHITTEPATI*.—1, Triffitt, Catta. *Chickens*.—1, J. Watson. *BARNDOR or CROSS BREED*.—1, Mrs. Gunter. 2, O. A. Young. *Chickens*.—1, Mrs. Gunter. *ANY DISTINCT BREED*.—1, R. R. Farrer. 2, H. S. Thompson. *Chickens*.—1, Knowles, Wetherby. 2, J. Watson. *BANTAM*.—*Silver or Gold-laced*.—1, O. A. Young. *Black*.—1, J. Watson. *Any other Variety*.—1, O. A. Young. 2, J. Watson. *Cockers*.—1, J. C. Taylor. 2 and 3, O. A. Young. *EXTRA STOCK*.—*Rabbits*.—1, G. Chambers (Angora). *he* (Spanish).—1, Watson. 2, J. Watson. 3, R. Vincent. 4, W. H. Roberts, Spofforth. *he*, O. A. Young.

JUDGE.—Mr. E. Hutton, Pudsey, Leeds.

WELSHPOOL POULTRY SHOW.

This Poultry Show in connection with the Montgomeryshire Agricultural Society was held at Welshpool on the 23rd inst. The *Dorkings* and "Any Variety" classes were well represented. Subjoined is the prize list:—

GAME.—*Black or Brown Red*.—1 and 2, E. Pugh, Welshpool. *he*, Capt. Beck, Galsfield. *Cock*.—1, Capt. Beck. 2, E. C. Pugh. *DORKINGS*.—1, 2, and *he*, Miss Williams, Henllys, Berriew. *SPANISH*.—1, P. L. Edwards, Montgomery. *HAMBURGS*.—*Black*.—1, T. Morris, Henfoes. *Gold or Silver-spangled or Pencilled*.—1, J. Morris, Welshpool. 2, W. Rogers, Welshpool. *ANY OTHER VARIETY*.—1 and 2, Miss Williams. *he*, Miss Williams; F. Williams, Kerry. *DUCKS*.—*Rouen*.—1, Capt. Beck. 2, W. Yearels, Spring Bank. *he*, Miss Williams. *GEESE*.—1, Mrs. Lloyd, Mydod. 2, G. Evans, Moelygarth. *TURKEYS*. 1, Miss Williams.

JUDGE.—Rev. A. G. Brooke, Rayton XI-Towns, Salop.

BRECONSHIRE AGRICULTURAL SOCIETY'S POULTRY SHOW.

The first show of poultry was held in the Cattle Market, Brecon, on the 21st inst. It was well conducted, and great interest was shown by the Committee in the welfare of the poultry entrusted to their care.

In the class for *Red Game* the birds were very poor, but the *Dorkings* were nearly as good as we have seen this season. The *Dorkings* were numerous, and some of the birds good; and the winning *Cochins* were both Buff, the first-prize birds being chickens, and the second adults. The local cup was won by a pen of *Dark Brahmas*; the second and third prize birds in the Brahma class were both Light, and all three pens were very good. The first-prize *Silver-spangled* were the only birds of merit in the *Hamburg* classes. The *Game Bantams* were in good numbers, the first being *Black Reds* of good quality, and the second *Brown Reds*; and in the "Variety class," Blacks were first and *Rumpless* second. There were some excellent *Ducks*, both *Aylesbury* and *Rouen*, and the local cup for aquatic birds was won by the *Aylesburys*. The *Geese* were large and in excellent order; white *Emden* first, with *Toulouse* second; and of the *Turkeys*, Blacks were first and handsome Whites second.

GAME.—*Black or Brown-breasted Red*.—1, Withheld. 2, W. Williams. *Any Variety*.—1, G. S. Cole, Llanelly. 2, J. Mitchell, Birmingham. *SPANISH*.—1, T. A. V. Vastalyfara. 2, W. Davies, Brecon. *DORKINGS* (Any variety).—1, E. Shaw, Plas Wmot, Oswestry. 2, R. Rees, Dorigan. 3, Rev. H. Price, Llanfynyach. *COCHIN-CHINAS* (Any variety).—1, — Thomas. 2, D. W. J. Thomas. 3, J. P. Gwynne, Holford, M.P., Heolias. *BRAHMA POOTERS* (Any variety).—1 and Special prize for best pen of Fowls, Rev. J. Bowen, Treffarnne. 2, Rev. N. J. Ridley, Newbury. 3, T. A. Dean, Moreton-on-Lugg. *he*, Rev. L. U. Jones, Llanugast, Brecon; Rev. J. J. Evans, Cantref. c, G. J. May, Neath. *HAMBURGS*.—*Gold and Silver-spangled*.—1, J. H. Howe, Newport, Manchester. 2, Miss G. E. Palmer, Lichborne, Warwick. *he*, W. White, Gloucester. *ANY OTHER VARIETY*.—1, Mrs. E. Williams, Henllys, Berriew, Montgomeryshire (Crested). 2, J. H. Howe. 3, Rev. N. J. Ridley, Newbury (French). *GAME BANTAMS*.—1, Mrs. E. C. Phillips, Yennfych, Brecon. 2, — Lewis, Abergavenny. *he*, J. Mayo, Gloucester; F. Cooper, Cirencester. c, E. C. Phillips. *Any variety*.—1, S. & R. Ashton, Mottram, Cheshire (Black). 2, F. Cooper (Rumpless). *SELLING CLASS*.—1, J. P. G. Holford, M.P. (Dorkings). 2, H. E. Thomas, Brecon (Cochin-China). 3, F. W. Garbutt, Newport (Andalusian). *he*, J. H. Lanford, Rustington, Bristol (Polish). c, T. T. Evans; E. Webb, Brecon (Cochin-China). *EXTRA CLASS*.—Prize given by C. A. Wood, Esq.—1, T. Gabriel, Devynock (Spanish). 1, D. W. J. Thomas (Cochins). 2, Rev. H. Price, Llanfynyach (Dorkings). *he*, H. E. Thomas (Cochins). c, H. E. Thomas (Cochins); E. C. Phillips (Duckwing Game); W. Parker, Brecon (Game Bantams). *DUCKS*.—*Aylesbury*.—1 and Special prize for best pen of Ducks, E. C. Phillips. 2, D. Llan, Bardwick, Gloucester. *he*, E. C. Phillips. c, Holford. *Bantam*.—1, W. Cooper, Abergavenny. 2, E. Shaw. *he*, Rev. J. J. Evans; W. Lewis, Abergavenny; — Richards, Llanfaes, *Selling Class*.—1, E. Shaw (Rouen). 2, J. P. G. Holford, M.P. (Rouen). 3, J. J. Evans (Rouen). *SWEETSTAKES*.—1, E. C. Phillips (Game Cock). *GEESE*.—1, R. Rees. 2, T. Edwards, Brecon (Grey). *he*, R. Rees; E. Shaw (Toulouse); T. E. Trev, Rhydymed, Brecon. *TURKEYS*.—1, Mrs. G. Holford (Black). 2, R. Parry, Penlan, Brecon (White).

JUDGE.—Mr. E. Hutton, Pudsey, Leeds.

WALSALL POULTRY SHOW.

This formed part of the Staffordshire Agricultural Society's Exhibition, and took place on the 22nd inst. It was a decided success. The day was remarkably fine, and the visitors were so numerous that it was almost impossible to pass through the poultry tent, although it was unusually spacious. The show of poultry was unquestionably good, though, perhaps, somewhat reduced as to the number of pens, from the fact of three or four other noted shows taking place the same week. With the exception of *Turkeys*, all birds shown were to be of this year, yet, whether by negligence or design, several old birds were exhibited, and necessarily without success. *Game* were good, *Spanish* equally so, but in this class the most barfaced ease of trimming took place that has been noted for many months past, instant disqualification ensuing. Many good *Grey Dorkings* were shown, and one pen of capital White. *Buff Cochins* were, with the exception of

the prize pens, not so perfect as expected, but the Partridge-coloured were first-rate. The *Hamburgh* classes were exceedingly strong. The Duke of Sutherland took all the principal prizes with really grand pens. Some very good *Brahmas*, both Light and Dark, were shown, but mostly too young to be in good show trim. It will take at least a month, perhaps six weeks longer, to bring them to perfection. *Turkeys, Geese, and Ducks* were strong classes as to excellence, but the more than questionable ages of some of the so-called Goslings caused considerable merriment among the bystanders and loss of expenses to the contributors. The "Variety class" was unusually good, there being far too many perfect pens to do justice to all; but as the awards were restricted to two prizes, high commendations and one very high commendation were all that could under the circumstances be given, much to the expressed regret of the Judges. The management of the birds devolved on Mr. Thomas Rogers, of Walsall, who well fulfilled the triple duty of packing, repacking, and feeding the birds.

GAME.—*Black-breasted and other Reds.*—1 and 2, W. H. L. Clare, Twyross, Atherstone. *Drab.*—1, Draycott, Radlett. *Another Variety.*—1, W. Duensing, Newport, Salop. 2, J. Mitchell, Moseley, Birmingham. *he, J. Brasington, Longton.* **SPANISH.**—1, H. F. Cooper, Walsall. 2, J. H. Dawes, Moseley Hall, Birmingham. *Disqualified, J. F. Silthoe, Penn Fields, Wolverhampton.*—1, "trimmed." **DORKINGS—Coloured, except Silver-Greys.**—1, H. Pickles, jun., Earby. 2, C. Havers, Inglestone. *he, J. Watts, Hazelwell Hall, King's Heath, Birmingham.* *Silver-Grey or White.*—1, Miss E. Williams, Bentley, Berrys. **COCHIN-CHINAS.**—*Buff.*—1, W. F. Ryland, Erdington, Birmingham. 2, G. Sidgwick, Ryddlesden Hall, Keighley. c. J. Stephens, Walsall. *Brown, Partridge-feathered, or other Varieties.*—1 and 2, J. Stephens, *he, C. Sidgwick, BRAHMA POOTRAS.*—*Dark.*—1, E. Leech, Rochdale. 2, G. F. Whitehouse, King's Heath, Birmingham. *he, S. A. Cooper, Walsall.* *Light.*—1 and 2, Mrs. A. Williamson, Queenborough Hall, Leicester. *he, H. Dowsett, Pleshey, Chelmsford.* c. A. O. Worthington, Newton Park, Burton-on-Trent. **HAMBOURG.**—*Gold-spangled.*—1 and *he, Duke of Sutherland, Ryddlesden Hall, Keighley, Yorkshire.* c. W. K. Tucker, Ipswich. *he, Pickles, jun., Silver-spangled.*—1 and *he, Duke of Sutherland, 2, H. Pickles, jun., Golden-spangled.*—1, Duke of Sutherland. 2, T. May, Wolverhampton. c. G. F. Whitehouse; T. Boulton, Hinford, Stoke-on-Trent. *Silver-spangled.*—1, Duke of Sutherland. 2, G. Brown, Sandhills, Walsall. *he, H. Pickles, jun.; G. Brown, TURKEYS.*—1, F. E. Richardson, Bramshall, Uttoxeter. 2, E. Leech, *he, Rev. E. C. Perry, Selchorth Vicarage, Stafford; Rev. J. H. Holliday, Holliday House, Northwich, Cheshire.* c. W. S. Scatton, Hartwell, Aylesbury. 2, E. Leech, *DUCKS.*—*Aylesbury.*—1, E. Leech. 2 and *he, Mrs. Scamsons, Rouen.*—1, S. H. Stott, Quarry Hill, Rochdale. 2, E. Leech, *he, Duke of Sutherland; S. H. Stott, c. A. O. Worthington.* *Any other Variety.*—1, J. Stephens. 2, A. O. Worthington. **ANY OTHER VARIETY**—1, Duke of Sutherland (Black Hamburghs). 2, H. Pickles, jun. (Silver Poland). *he, Miss E. Williams (Crève-Cœur).* *he, A. D. Payne, Lyth Hill, Shrewsbury (Malays); Miss E. Williams (Houdans); J. Watts (Black Hamburghs).* c. J. Stephens (Bantams).

Mr. Edward Hewitt, of Birmingham, and the Rev. G. A. Crooke, Ruyton XI-Towns, Salop, were the Judges.

WOODSTOCK POULTRY SHOW.

This was held in Blenheim Park on the 20th inst., and was the largest yet seen at Woodstock. The *Tycons*, *Aylesbury* ducklings, and *Rouen Ducks* were good. In the "Any other variety" Duck class most of the honours went to the Black East Indians shown by Mr. W. R. Pratt. The *Geese* and *Dorkings* were very fine.

SPANISH.—1 and 2, Mr. King, Oxford. **DORKINGS.**—1, Mr. Hunt, Thrup. 2, Duchess of Marlborough. 3, Mr. Salter. *Chickens.*—1, Mr. Salter, Oxford. 2 and 3, Duchess of Marlborough, Blenheim. c. Mr. Woodford. **BRAHMAS.**—1, Hon. Mrs. Devereux. 2, Col. Thomas. *Chickens.*—1, Hon. Mrs. Devereux. 2, Col. Thomas. **COCHINS.**—1, Mr. Johnson. 2, Mr. Salter, Oxford. **HAMBOURG.**—*Spangled.*—1, Mr. King. 2, Mr. Scott. *Pencil.*—1, Mr. Salter. 2, Mr. Amies. *Chickens.*—1, Mr. Amies. 2, Mr. Hunt. *Game.*—1, Mr. Hunt. 2, Mr. Woodford. *Chickens.*—1, Mr. Hunt. 2, Mr. Woodford. **BANTAMS.**—1, Mr. King. 2, Mr. Quarterman. **ANY OTHER VARIETY.**—1, Mr. Stevenson. 2, Mr. King. **GESE.**—1, Mr. Sanders. 2, Duchess of Marlborough. 3, Mr. H. Barnett. 4, Mr. G. Blake. **DUCKS.**—*Aylesbury.*—1, Mr. Quarterman. 2, Col. Bowyer. 3, Duchess of Marlborough. *Ducklings.*—1, Mr. Amies. 2, Mr. Bateman. 3, Col. Bowyer. *he, Mr. Quarterman.* c. Mr. Woodfield. **ROUEN.**—1 and 2, Mr. Salter. *Ducklings.*—1, Mr. Hunt. 2, Mr. Woodford. *he, Mr. Pratt; Mr. Quarterman.* *Any other Variety.*—1, Mr. Pratt. 2, Mr. Lester. *Young.*—1, 2, and *he, Mr. Pratt.* **TURKEYS.**—*Black.*—1 and 2, Duchess of Marlborough. *Grey.*—1 and *he, Col. Bowyer.* 2, Duchess of Marlborough. **PIGEONS.**—1, 2, and 3, Mr. Salter. *he, Mr. Salter; Mr. Pratt.*

SPECIAL PRIZES given by the Duchess of Marlborough for a collection of poultry.—1, Mr. Woodford. 2, Mr. Hunt. *he, Mr. Pratt.* Champion prize given by the Earl of Jersey for best pen of young poultry.—Mr. Amies (Aylesbury Ducks). *Old.*—Duchess of Marlborough (Black Turkeys).

Mr. H. Yardley, of Birmingham, was Judge.

USES OF CARBOLIC ACID.

In "our Journal" of September 2nd, 1869, reference was made to the employment by "APICOLA," of a piece of sponge dipped in carbolic acid, and inserted in a fumigator, whereby the use of burning material to produce smoke was rendered unnecessary. I have now to add, that by the aid of a feather having its tip wetted with the acid most operations in the apiary may be comfortably performed. If it is desired to examine a Woodbury hive, the procedure may be as follows:—Open the central hole and touch the bees that crowd around it with the acid, and they will immediately descend helter-skelter amongst the combs. In the next place gently raise the top board just enough to allow the feather to be drawn all round between it and the frames. As soon as this is done the board may be removed, and the frames elevated, using if necessary the feather to quiet and disperse any angry groups that threaten to be troublesome.

During the swarming season I have found the acid a useful

auxiliary. You can chase the bees with it upwards or downwards at pleasure, from the stems of bushes on which swarms have settled, and from which they cannot be shaken. When lodged in the decayed heart of a tree to which there is access only by a small hole, the swarm can be brought to the outside by simply tying the feather on a flexible rod, and thrusting it beyond them. When far down in a chimney they can in the same way be driven up towards the top until they are within reach.

The feather and acid are also of great service when cutting out combs from the roof of a house; for in a few seconds any comb to be removed can be cleared of every bee, thus leaving the operator a freedom he would not otherwise enjoy.

The acid, no doubt, has an unpleasant odour, but its influence, when brought in contact with the wood or sealed combs in the interior of the hive, is rather beneficial than otherwise. It evaporates rapidly, and a few hours suffice to remove all evidence of its presence. Hives frequently subjected to its odour flourish amazingly, and I can well believe that it acts as a powerful agent in checking incipient disease. I have always a phial or two of it standing in my bee houses, and for a long time, when manipulating bees, I have had recourse to it alone, discarding all fumigators, whether in the shape of pipes or cigars. By thrusting a feather moistened by it into the mouth of a common straw hive, and slowly drawing it round the edge of the interior, it also answers to the preliminary of blowing a whiff of smoke in at the entrance previous to the turning-up of the hive in order to drive it.

By a little practice skilfully directed, I have no doubt that with the help of the agent referred to, any tyro would soon be able to control his bees in any situation, and direct them when they have swarmed round the thick stems of bushes into the skep or box placed near them which they are intended to occupy.

As an attraction or guide, it is desirable on setting down the skep or box to take from the cluster a handful of bees with a twig or spoon, and shake them into it. These pioneers raise a hum within, and the swarm enters more readily. This prerequisite is especially useful if the domicile intended is new, and has not been previously occupied. Bees run much more quickly into a hive to which remnants of comb adhere, than into one that has never been tenanted. Sometimes a swarm clusters all over and around the skep in which an attempt has been made to lodge them, but I have always found it a simple and easy process to drive them towards and in at the entrance with the carbolised feather.—R. S.

OUR LETTER BOX.

NORTHALLETON SHOW (W. J. S.).—We never had any notice of this Show in our columns. If a show is not of sufficient public importance to be advertised, it cannot deserve to be permanently recorded.

RUBARB BED IN POULTRY-YARD (F. C. H.).—Let the fowls run over it if they are not pests so far as the productiveness of a garden is concerned, but they are enemies to neatness. We are not sure they are not at times beneficial.

BREEDING COCHIN-CHINAS (Enthusiast).—We advise you to use a Lemon cock, at any rate for this next season; it will neutralise the effect of the Cinnamon. Cinnamon is not a favourite colour, but in Cochins classes for "Buff and Cinnamon" the common wording colour does not count, size and symmetry are essentials. Also straight combs and plain heads—i.e., not vulture heads.

FEEDING DORKINGS (C. W.).—Let them have a dry dasy rut with plenty of grass and other green meat; feed on ground oats mixed with milk, kitchen and table scraps, and meat chopped fine. You may feed this way for a month, and may twice a-week throw down a handful of peas to keep plumage. When you send them to the show wash their legs and feet quite clean. Let them have a basket that will allow them to stand upright comfortably, and let them have plenty of oat straw in it. It is always advisable to put fowls that are going to be shown together in a small pen for a few hours every day for a week before the show. They learn to know each other, and if they do not agree they will never be successful.

FRENCH BREEDS OF FOWLS (W. L.).—All the French breeds are good layers, and if any fowl has a speciality for laying in the winter, it is the Crève-Cœur. It also lays a very large egg. They are all non-sitters. The hardest is the Houdan, next the Crève-Cœur. The La Fleche are by no means hardy. We have kept Crève-Cœurs in confinement for many years, and they do well. An experiment, however, proved they lay one-third more eggs when at liberty than in confinement. You may safely choose either Houdan or Crève-Cœur. We think on the whole we prefer the latter. If you live in a town black plumage is preferable to black and white.

CHARACTERISTICS OF BLACK HAMBOURGERS (T. E.).—Perfectly black plumage, striking white deaf ear the size of a fourpenny-piece, well piked comb seated firmly on the head, and not too large, dark legs.

GAME FOWLS EOUPE (G. R.).—Your fowls are suffering from roup. Put none of them in a room, they will get worse. Give them all a dose of castor oil. Discontinue the maize. Wash their faces and nostrils with cold water and vinegar. Give pills of euphor only, each pill the size of a golden pen. Keep the houses and runs very clean. Give bread steeped in strong ale for food in damp and cold weather. Keep the diseased cock separate from the others. Baily's pills are to be had at most chemists, or at 113, Mount Street, London, W.

BILLS OF DUCKS (Sheffield).—No weight would justify a judge in giving

a prize to Aylesbury or Ronen Ducks with bad bills. The bills should be wetted and then rubbed with pumice stone till the outer skin is removed. Some rub them with sand. It improves the bills of Ducks if they are allowed to run in meadows when the cold dew is on the grass. Dark water makes dark bills, especially pent water. The colour of them is improved by having stone grit in the water.

FOWLS FOR FAMILY USE (A Monthly Reader).—You may depend upon it that no fowl will do so well in confinement as at liberty, and no fowl suffers so much from being shut up as a Poking. The fertility of eggs depends much on weather, they fail more frequently in severe, especially snowy weather, than any other; they are also frequently frosted and chilled. You cannot expect to have good sitters when you mix breeds as you do. You have Silver Hamburgs, they are non-sitters. It is very likely among the seven mixed breeds you have others. You are wilfully causing that of which you complain. Situated as you are, we see no necessity for mixed breeds at all. There is no breed that will produce eggs and chickens without proper feeding and painstaking. Where this is carried out any breed will do well. It would be far more satisfactory to us to keep only one breed. You have probably been led away like many others. When complaining you had no eggs, you were told it was because you had no Hamburgs, you bought some; still wanting eggs you were told of another breed, and you still want eggs. There is, however, a light breaking-in upon you. You say you will have earlier eggs because you have earlier pullets. You are right, and we tell you the sooner they begin to lay, the earlier they will be broody. Feed your fowls well, gather the eggs as fast as they are laid, and keep the earliest pullets every year for stock. We advise you to keep to one breed. Dorkings are best, Brahma Pootras the least trouble. We conclude as we began, never shut up a fowl if you can allow it to be at liberty.

OWL PIGEONS (A. Jackson).—The classing of Owls does not so much depend on colour as size and appearance. The African Owls are exceedingly diminutive, they to English Owls are what Short-faced Tumblers are to their longer-faced brethren. Yellow is a colour sometimes met with in English Owls. Most probably yours are English. The colour of the eye in Owls should be pearl or gravel.

DIARRHŒA IN POUTERS (H. V. S.).—Put a little sulphate of iron in their drinking water sufficient to give a decidedly inky taste. Feed entirely on old beans for a time, crum them if necessary. Put down their throats each day three hits of omentherm the size of a pea. Cleanse and lincwash the loft thoroughly, sprinkle the workwood with chloride of lime, and separate the diseased from the healthy. Pouters are very liable to diarrhœa.

SEPARATING POUTERS (P. G.).—It is not at all necessary to separate Pouters during the winter. The great Scotch fanciers do not, they merely turn the pens inside down, or remove all places of laying.

POINTS OF LOP-EARED RABBITS (A. B.).—Lop-eared Rabbits are generally judged from the seven following points when for all properties. 1st. Length of ear from tip to tip; 2, width of ear; 3, colour, as blue and white, black and white; yellow and white, grey and white, tortoiseshell or self; 4, position of ears; 5, size of eye, and the larger the better; 6, carriage of the body; 7, size. It is not often that a Rabbit is perfect in all these points, yet the nearer it approaches perfection the better, and such a specimen is of great value.

CIDER MAKING (C. T.).—The quantity of apples required for making a gallon of cider depends upon the soil, season, and the kind of apple employed, but we know it has been calculated that one peck of the best cider apples ought to yield a gallon of juice. In the grinding the fruit should be reduced as nearly as possible to a uniform consistence, in such a manner that the rinds and kernels may be scarcely discernible from the general mass, the operation proceeding slowly, with a free access of air. **Preparing the ground fruit.**—The pompage should be carried to the press in from about eighteen to twenty-four hours, and a square cake or cheese made of it by placing very clean sweet straw or reeds between the alternate layers of pulp, or pompage, or by putting it into haircloths spread upon the vats, and placing them one upon another; they are turned up on the sides, and cover over the pulp, so as nearly to meet in the centres. They should be laid very even, and ten or twelve may be laid over each other in regular layers, the square frame of the press being raised with them, keeping the pile of a uniform size. Upon the whole a strong board is placed, wider than the pile, on which the blocks of the press rest. It is of the utmost importance that the straw or reed, where it is used, should be sweet and perfectly free from fastness. Particular care ought also to be taken to keep the hair cloths sweet by frequently washing and drying. To this cake or cheese, after standing awhile, a slight pressure is at first to be given by lowering the screw of the press, which must be gradually increased as the cakes become drier, until all the must or juice is expressed, which is usually completed by a long lever and windlass, after which the juice must be strained through a coarse hair sieve, and put either into open vats or close casks. **Fermentation.**—Fermentation should not, by too much heat, be carried on too rapidly, nor by extreme cold too slowly. The degree of warmth may be understood to be between 40° or 50° of Fahrenheit's thermometer. When the liquor appears tolerably clear, and has a piquant viscus sharpness on the tongue, then the least hissing noise heard in the fermenting liquor in this state shows that the place in which it stands is too warm, and that air must be admitted. This is the critical moment for racking the liquor, which is done by drawing off the pure part into open vessels, which must be placed in a more cool situation for a day or two, after which it may be again barrelled and placed in some moderately cool situation for the winter. The casks into which the liquor is put, whenever racked off, should always be previously thoroughly scalded and dried again, and each should want several gallons of being full, to expose a larger surface to the air. Having attended to these rules so far, the cider will require very little further attention beyond filling up the vessels every two or three weeks, to supply the waste by the insensible fermentation, until the beginning of the succeeding March, at which time it may be reasonably expected the cider will be bright, pure, and in a fit state for its final racking. This should be done in fair weather; but should the cider not prove as bright and of as good a colour as desired, put 2 lbs. of lump sugar into a hoghead of cider. If you wish the cider to be of a higher colour than the fruit gives it, melt 1 lb. of loaf sugar in a stewpan over a clear fire, stirring it frequently until it comes to a very dark brown colour; then take it off the fire, and as it cools add some cider by little and little, continuing to stir it till it becomes a thin uniform fluid. About a pint of this colouring to a hoghead of cider is sufficient. Soon after the spring racking the casks may be gradually stopped by first laying the cork on the bung-hole, and in the course of a

few days forcing it very tightly into it, covering it over with melted resin, or any other similar substance. **Bottling the Cider.**—This should be done a month after the spring rackings, when the liquor has acquired in the cask its highest degree of perfection; then, when the weather is fair, let the bottles be filled, setting them by uncorked until the morning; then let the corks be driven very tightly into the necks of the bottles, tied down with small strong twine or wire, and well secured with melted resin.

BLACKBERRY WINE (Jane).—Put fully ripe blackberries into a large vessel with a tap to it; pour on as much boiling water as will cover them, and, as soon as the heat will permit, bruise them well with the hand till all the berries are broken; cover them, and in about three or four days, when the berries rise to the top, draw off the clear part into another vessel; add to every ten quarts of the liquor 1 lb. of sugar; stir it well in, and let it stand a week or ten days to work. Draw it off through a jelly-bag. Steep 4 ozs. of isinglass in one pint of sweet wine for twelve hours; then boil it slowly till dissolved; put it into one gallon of the blackberry-juice; boil them, and put all together. Let it stand a few days, and bottle.

OBTAINING AN EARLY SWARM (Super).—You had better take off the super at once, and weigh the stock hive, if its nett contents are less than 17 to 18 lbs. the bees should be fed by means of an inverted pickle-bottle filled every evening until they attain that weight.

METEOROLOGICAL OBSERVATIONS

COVENT GARDEN MARKET.—SEPTEMBER 28.

The demand is steady, but very low prices are realised, although the general description of produce is better than it has been for some time past. Peaches and Nectarines continue to be well supplied, and late varieties of Dessert Plums are abundant and good. Potato trade heavy; large quantities are offered both by rail and coastwise.

From observations taken near London during the last forty-three years, the average day temperature of the week is 61.5°, and its night temperature 42.6°. The greatest heat was 77°, on the 9th, 1861; and the lowest cold 25°, on the 11th, 1860. The greatest fall of rain was 1.00 inch.

COPINGS FOR WALLS.

THAT walls are to a garden copings are to walls—namely, protection. The one is of little use without the other. I do not think a garden is of much use without a substantial wall, or its near relation a good, thick, well-kept hedge—it matters but little which, so far as protection or shelter goes; but a wall can be used for growing fruits, some of which cannot without such aids be produced in perfection in our climate, whilst

a hedge can be used for no such purpose, takes up as much space as the wall, and requires as much support from the soil as do the trees that are grown against the wall: hence there is more to be said in favour of a wall than a hedge. But some contend that walls do not break the force of the wind so well as a hedge. There is a difference in circumstances. A walled space enclosed on every side must at all times have a sheltered part, for when the wind is blowing from, say, the west, the east side of the wall, as well as the ground, will be shielded from the wind's violence for a considerable distance. "But the wind is only diverted, the current is made to whirl past the obstacles (the walls) to its straight course, and the garden is in no respect better, if so good, as a space unenclosed, or one enclosed by hedges." That the currents of air are made to take a different course by walls to what they would were there no obstacles to the wind's direct course no one can doubt; but that does not mean that the subjects within the enclosure are exposed to an increased violence of wind, for the wind being diverted from its course, it follows that its force is either broken, directed upwards, or turned backwards from the obstacle against which it strikes. If the wind be driven upwards by a wall we know that the space for a considerable distance on the other side will derive considerable benefit, or be protected from its violence; for it is an error to suppose the wind runs up one side of a wall and down the other. If, on the other hand, the wind is thrown back, the force is broken, and the subjects on that side must feel its effects in being driven from the object against which the wind strikes.

Now, if walls are no protection, if they do not afford shelter to the space they enclose, how is it that the subjects on them are so much earlier and less damaged than those growing in open spaces? How does it happen that in unenclosed gardens the fruit is driven from the trees if strong gales occur when it is fit, or nearly so, for gathering? If walls are the cause of so much mischief by creating currents, how is it that the fruit on the trees grown against them are seldom, if ever, injured by winds? They receive its force, and sustain no damage from its violence. I cannot understand the ideas some have of walls, but I do know that unless walls are covered with trees—i. e., foliage, the winds glide from them in a way not beneficial to the plants in the ground adjoining. The wind increases in force as it runs along the wall, and it tears up whatever is in the ground near; but cover the wall with trees in leaf, or when

leaves are not there, with innumerable small branches or obstacles to the wind's running along, and its force is broken by the surface with which it comes in contact. A bare smooth surface such as a wall is of very little use in breaking the force of wind, but anything covered with foliage, whether it be a hedge or fence, is good, for the innumerable obstacles to the free passage of the wind diminish its force and reduce to a minimum the injury it does. And so it is with walls—covered with foliage they are unequalled for protection, but when bare their utility is questionable; indeed, they are then no better than a hedge, for though the hedge allows the air to pass through, the wind's force is broken, and what is lost in the space required for the roots of the hedge-plants is not more than that wasted by the exercise of the wind's force against the wall. But what has that to do with copings? Simply this, that if there is no need for walls, there is less for copings.

Walls should always be coped, otherwise the wet enters the upper part by the joints of the masonry, destroys the mortar, or whatever is used to bind the materials together, and this gone the wall soon crumbles and falls. If a wall be worth building it is worth coping, and in such a manner that the rain falling on it will run off clear of the wall, for when the coping is no wider than the wall, the latter is very little better than a wall uncoped. The rain or wet runs down one or both sides of the wall, and from the wet the mortar soon perishes and falls off, the material of which the wall is constructed being often seriously damaged.

The coping should be wide enough to cover the wall and project somewhat on both sides. There is some difference of opinion as to how much projection the coping ought to have. Some advise a considerable projection, and others but little. From the experience of both wide and narrow projecting copings I am persuaded that the latter are preferable. Two inches' projection, I am convinced, is sufficient, for a considerably wider coping than that deprives the trees of the rains and dew so refreshing to their foliage, and I am of opinion that one good natural wetting is worth half a dozen artificial ones. A wide coping not only keeps the rains and dew from the trees to a considerable extent, but the water from the coping is made to drip clear of the trees, forming all along the wall quite a channel, throwing the soil upon the lower branches, and spoiling the fruit, besides making the ground at the foot of the wall wholly unsuitable for the growth of Lettuces, &c. I am aware that some advocate a wide coping, on the ground that it checks the passing upwards of the heat. This is, no doubt, a consideration, and into it I shall enter hereafter; but a permanent coping with 2 inches' projection is all that I have found necessary for the wall—and for the trees, too, except at certain seasons.

The best coping of all is stone. It need not be more than 3 inches thick, and it ought not to be flat, but being three-quarters of an inch less in thickness on one side than the other, the water will run to that side, and the underside of that having a small throat or groove about half an inch from the edge, it will keep the water from running down the wall. The coping should have cemented joints,

The incline should be to that side of the wall of the least importance; for instance, when a wall runs east and west the coping should fall to the north, whilst if it runs north and south the coping should incline to the west, it being presumed that the east side is for Plums, Cherries, &c., and the west for Pears.

Some prefer the coping highest in the centre, with an incline to each side. This I think quite unnecessary, a flat coping with the needful incline being, in my opinion, preferable. If anything, I would have the coping hollow in the centre, inclining from the sides to the middle, along which there might be a groove falling to a certain point, from which the water could be conveyed to the ground by a spout. This would do away with drip from the wall altogether, and the expense not being much more, I would strongly advise its adoption as the best plan of all.

Next to stone, Portland stone cement coping is desirable. It closely resembles stone in appearance, is very durable, and, I am obliged to add, expensive. Slate forms a first-class coping, but is very poor in appearance compared with either stone or cement, and unless well secured is liable to get displaced. Tiles made of fireclay answer admirably. They require to be well burned, and if blue all the better. When they are red I have not found them stand frost for any great length of time. The blue colour, I believe, is given in glazing by the agency of salt used in the burning. They are usually 2½ inches thick. Very thin or light copings of any kind have a mean appearance.

As regards other copings besides that formed on the wall it is important to have one specially for the protection of the trees, for heat has a tendency to ascend, and if it be prevented doing so it cannot pass away so rapidly. Another advantage of what I shall term a tree coping is checking the downward passage of cold air, for as it is the tendency of heated air to rise, so is it of cold air to descend. In spring when frosts prevail a coping is very valuable from keeping the blossom and young fruit dry, in which state they are not so liable to injury from frost. A third advantage of this kind of coping is, that in autumn we may secure the trees having more heat and dryness than where no provision of the kind is made, and not only make certain of the full ripening of the fruit, but also of the wood for another season fruiting. It may be said, if a coping of this kind is necessary (I do not say that it is, but I consider it an advantage), why not have it permanent? I consider that it deprives the trees of the rains and dews when making their growth and swelling their fruit, and that in winter it is wholly unnecessary, the trees being all the better of its removal, for nothing in my opinion is so destructive to insect life as frost and rain.

The sort of coping I would have is a moveable one that could be put up one day and taken down the other. So far as I have experience no material is better than wood. It is lighter than many others, and when well painted lasts a long time. An inch-deal 11 inches wide answers perfectly. This width I think needful for Peaches, Apricots, Pears, and Plums, as the latter two often have their spurs some distance from the wall; but I have known 9-inch boards employed with good effect. They should be planed smooth and well painted. There is some difficulty in fixing them so as to look well. There is no question that brackets are best, but even these are very ugly if left after the coping-boards are removed, hence the supports of the coping-boards ought not to be fixtures, but, like that they uphold, be removable.

This may be effected in a variety of ways, but a good method is to fix to the face of the wall pieces of iron 1½ inch by half an inch, and 13 inches in length, with a square hole at the top 1½ inch by three-quarters of an inch, and another of half an inch, 9 inches from the top hole, with two holes for bolts to drive into the wall. The plate will on the face have the appearance of A. The plate should be let into the under side of the coping up to the top of the upper square hole, and before driving in the bolts a space an inch longer, and the same size in other respects as the upper hole, must be cut out of the face of the wall 1½ inch deep opposite to where the plate is to be fixed. The distance apart ought not to exceed 6 feet. Wrought iron is most suitable, and should be well secured by the bolts above named. These plates are to remain permanently fixed to the wall.

The brackets are of cast iron, and though they are not different in pattern from those for shelves, instead of screw-holes, they have at the top a lug 1½ inch long one way, and 1½ inch the other, and a stud at the bottom which fits the

lower square hole in the plate. The use of the lugs will be seen on reference to B.

To fix them, all we have to do is to put the top lug through the top hole in the plate and let it drop; it will hang by the lug and cannot by any possibility fall out, and the bottom lug drops in the lower square hole in the plate. The coping-boards are then put on and will fit exactly beneath the coping;

having an incline outwards, the water will drop clear of the trees. A screw will keep the board from being dislodged, a hole being at the end of the bracket, that is within an inch of the end. The whole can be taken down and put up at will, has a neat appearance when up, and there is no ugly projecting support when taken down.

The time to use the coping-boards is in spring when the blossom is approaching expansion, continuing them until danger from spring frosts is past. They may be again used in autumn when the fruit is ripening until the leaves fall, after which they should be taken down.—G. ABBEY.

BEDDING GERANIUMS.

As it is the fashion just now to report in your pages about these favourites of the garden, I feel constrained to say a few words about those which I have found answer best with me, and those which I think most promising for the future. I will begin with stating that the soil of my garden is a rich clay loam of some depth, resting on a subsoil of cold blue clay of a very unctuous character. I wish all persons in telling their experience with Geraniums or other flowers, would also describe the soil in which they grow them, otherwise their experience, however carefully reported, is of little practical use to your readers.

I may also state that my garden aims to combine something of the landscape as well as of the flower garden. There is as little formality in it as possible, but every available nook or projection in the shrubbery or the drive which leads up to the house by a winding curve is made use of to assist the general effect by a series of surprises, as it were, so that whichever way you look there is something new and diverse from anything else in the garden. I avoid as much as possible great masses of flowers of the same kind, which, to my taste, appear vulgar and offensive. Also here and there, backing up or dividing the beds, which are devoted specially to the display of any particular kind of flower, are mixed borders, which afford relief and lead on the eye to other beauties *en petite masse*. My friends admire very much in my garden the use I make of atumps, of which I have several surrounded with borders, the general effect being that of huge nosegays of various Geraniums or other flowers of differing foliage and bloom, so arranged as to bring out strong contrasts of colours.

Owing to the kindness of a friend, who is well known in the floricultural world, but who shall be nameless here for obvious reasons which he will appreciate, I have been able to enjoy and to test the value of a great number of Geraniums and other flowers, which, but for his goodness, I should, perhaps, never have possessed. Some of these I will now proceed to describe, only let your readers bear in mind what I said regarding the soil in which they are grown. In moist seasons they would, doubtless, vary in their growth. As it is, they have not grown at all rampantly, neither have they suffered from drought, as my neighbours' plants on different and lighter soils have done.

I begin with the Tricolors, which I admire exceedingly, and to which I assign the palm of beauty over all Geraniums. I have tried the following:—Mrs. Pollock, Sophia Cusack, Lady

Cullum, Defiance, Sultana Valida, Queen Victoria, Sir Robert Napier, Louisa Smith, Prince of Wales, Oberon, and Titania. Of these, the best in every way I have found to be Sir Robert Napier, by far the most distinct of this class. There is an indescribable depth and richness in the foliage, which makes it a very striking plant; but its greatest merits are—first, the facility with which it can be propagated, every cutting rooting easily, whether in the greenhouse or in the open ground; secondly, the remarkably full and vigorous habit of the plant. In these respects it is just the reverse of Mrs. Pollock. There is no legginess at all about it, and in the multitude of side shoots it throws out, it beats almost every Geranium I know. Of the rest, Mrs. Pollock comes second, but a long way after it. Prince of Wales is gorgeous as a pot plant, but it has done nothing out of doors, having, in fact, dwindled away rather than increased in size. The same may be said of Sultana Valida, Titania, and Queen Victoria. The others have done fairly, Oberon giving me a few nice cuttings well struck; but none of these do I consider promising, except as single specimens for pot culture. Titania is lovely as a pot plant; so are Defiance, Lady Cullum, and Sophia Cuesck.—B. & W.

(To be continued.)

MELONS OUT OF DOORS.

In the hope of eliciting further information from some of your correspondents on this subject, I send you a short account of the results attending my cultivation of out-door Melons this season. I should say that the idea of growing Melons in the open air was first suggested to me by a letter which appeared in the *Gardeners' Chronicle*, of December, 1869, relating the grower's own experience in the matter, from which it seemed he had not been successful last season owing to the early frosts, but thought another year success might be accomplished.

Determined to try what could be done, I wrote at the beginning of April to Messrs. Carter for a shilling's worth of the hardy ridge Melon, called Acharapennischer, a name not easily pronounced, and with greater difficulty spelt, and more easily sneezed than either. However, what's in a name? The proof of a Melon is in the eating. For my shilling I got eight seeds, which I placed in a pan, in a bed made-up for other Melons. Of the eight seeds seven came up, and in course of time the seedlings were potted off, though unfortunately three met with an untimely death from scorching. The remaining four plants were turned out at the end of May, on three little ridges, made as for hardy Cucumbers, of about 2 feet in depth of warm manure and 1 foot of common garden soil. The position was in the middle of the garden with no wall near, and on a bank sloping from the south, no other spot being just then available. A little hand-glass was put over each, and as the plants grew it was lifted higher and higher to allow them to extend.

By the third week in June they were well established and setting fruit. No particular attention was paid to them beyond an occasional watering, and, therefore, they did not probably set so many fruit as if the blossom had been carefully impregnated.

The first Melon was cut the first week in August, but it was not weighed or measured owing to my absence from home. At a rough guess I should say it weighed between 3 and 4 lbs. A second was cut the third week in August; it weighed 4 lbs. 15 ozs., and was 25 inches in circumference. A third, cut September 7th, weighed 4 lb. 8 ozs., and measured 24 inches round. A fourth (the largest of all), cut September 17th, weighed 7 lbs. 2 ozs., and measured 27 inches. A fifth, cut September 28th, weighed 6 lbs. 8 ozs., and measured 26 inches. There are three yet remaining, though not nearly equal in size to the above. The vines have almost withered, but I have replaced what remains under the hand-glasses, and I doubt not the other Melons will ripen well. Of course size is no criterion of goodness, but these Melons were as fine in flavour as any I ever tasted. I had two lots of green-fleshed Melons under glass this year, but the out-door Melons were quite equal, if not superior to them in flavour. The flesh is a bright orange, firm but melting, juicy, sweet, highly flavoured, and eatable down to the rind. The fruit is round, rough-skinned, and slightly netted. The season has, no doubt, been exceptionally favourable to the growth of out-door Melons; but I believe in most summers, especially in rather a better situation, they will be found to do equally well. I should add that the opinion as to their flavour and appearance can be verified by many gentle-

folks and gardeners of the neighbourhood who have seen and tasted them.—G. J. BLOMFIELD, *Norton Rectory, Iminster, Somerset.*

MUSHROOMS IN A LONDON CELLAR.

[THE following answer to "E. S." will be of interest to many of our readers.]

THERE can be no question as to your being able to grow Mushrooms in a London cellar, provided it is moderately dry. Taken all-in-all, a good cellar deep enough down to maintain a pretty uniform temperature is about the best place for growing Mushrooms all the year round, as it is cool in summer so that the Mushroom beds may be open, and warm enough in winter to suit the Mushrooms, especially when a little covering of sweet hay or straw is put on the beds, if the place should be rather cold. A temperature of from 50° to 55° in the atmosphere, with from 10° to 15° more in the bed, and a rather still atmosphere, are about the best conditions for free Mushroom growing.

Now with regard to your first question—Whether to make the beds on the floor or on shelves? I do not think there is much difference, all things considered. It is easiest, and requires no additional outlay, to make the bed on the floor; and there is this advantage, that the beds may be deeper than those which temporary shelves would well support, and if you are a fresh hand, I would advise you to try beds on the floor before going to the expense of making platforms or shelves one above the other. However, if resolved to make the most of your room, you could have a bed on the floor, and as many beds on shelves above it as you could find space for, provided each shelf bed were about a foot in depth, and there were a space of from 24 to 30 inches between the beds to allow of headway and ease in examining the beds. If satisfied with a bed on the floor, it should not be less than a foot in depth, but if from 15 to 20 inches deep it would bear all the longer, and maintain for a longer time a mild uniform heat. The width of the beds is of little consequence; if ranging from 4 to 5 or 6 feet they will be easily examined; if wider you will have to step on the beds at times. Hence if the width of the cellar would permit of it, I would prefer having a walk—say 24 to 30 inches wide down the middle, and a bed of 4 or 5 feet in width on each side, in preference to having one bed of 8 to 10 feet in width. If the beds are made flat you will require something, as a board, to keep up the side or sides, but you may dispense with that if you please by building your bed in a slope considerably the highest against the back wall, and coming down to the floor. In this case the pathway would not require to be so wide. I have tried both modes, and cannot say which is the better for beginners. I prefer the flat beds.

Premising merely that you have much room, I would advise you, instead of making your beds all at once, to have from two to four successions.

I will now allude to the second inquiry, "What is the best method to pursue?" This involves also the best material to be used. Some time ago I described the different means to be adopted with different materials. In London the best and most easily obtained material would be horse droppings, with about half their bulk of short littery matter mingled with them, and if obtainable, about one-quarter of rough fresh fibry loam; but it is not always to be had, and we have had fine beds without any. Its chief use is preventing violent heating, and thus more strength is left for the production of Mushrooms. The most economical way to use the droppings, &c., where the quantity is small, is to add a few inches every alternate day to the bed, beating it well, until the requisite depth is attained. This plan might not be suitable for a cellar, if the material had to come through or close to the house, and it might be advisable to have enough to make a bed or a part of a bed at once. In this case collect or purchase as many droppings, &c., as you get well, let them be thrown in a place where no rain can get at them, then put them into a heap to sweat and heat, which will also make them as much drier as will be more suitable for a bed at once. After remaining in the heap three days or more they will mostly be in a good condition for forming the bed, and should be placed in layers about 3 inches deep, one layer being well beaten before the other is added, and so going on until the bed, if flat, is say 10 inches high at the front, and 14 inches high at the back. Much depends on the beating, as the air, being thus to a certain extent excluded, the heat will be less violent, but it will continue much longer. Most likely at first, though the material is dry rather than very

wet, the heat will be too strong, and must be carefully examined from day to day, either with a thermometer or with trial sticks, before inserting the spawn. If the sticks when tried are about the heat of new milk, or the bulb of the thermometer a few inches below the surface stands at from 80° to 90°, and especially if the heat is gradually declining, you may spawn with safety. This fall in the temperature is a matter of importance, for, if the heat is increasing, it will become too much for the spawn, and you may look in vain for Mushrooms; 80° and falling may be considered a safe heat to spawn at.

The spawn, if good, may be broken in pieces a little larger than walnuts, and placed firmly just beneath the dung at about 8 inches apart. If you place it deeper, the stirring of the bed might excite fresh heating. It is better to leave all solid and smooth to prevent this heating, and if on daily examining the bed you find the temperature still inclines to fall, then you may add from 1 to 2 inches of pure droppings all over the bed, and beat it firmly, which will slightly raise the temperature and encourage the spawn to run freely. If after this you find the temperature remain uniform, or if anything slightly declining, then the bed may be earthed over with from 1½ to 2 inches of good soil. This soil should be somewhat damp, but not wet, so that it may be beaten firmly together. When this is done make the surface smooth, water it with a fine rose, and shortly afterwards draw a clean spade firmly over it, so as to leave a clean, smooth, firm surface, which will enable you easily to clean the beds afterwards with a hair broom when necessary.

Several times, notwithstanding every care, I have had to take out the pieces of spawn because the bed became too hot. With the care alluded to above, I should say that this was necessary in the case of one out of two hundred beds. In a cellar there is no absolute necessity for covering the beds, but I have found a little covering of hay, straw, or even a mat a little raised over the bed a great equaliser of heat and moisture. After earthing, when the spawn is running, the heat will be gradually increased, but not to an injurious extent, and that is always a sure sign that the spawn is running; but if after earthing-up the bed should seem to be getting rather cool, a little covering will help to raise the temperature a little so as to produce the desired result. When watering is necessary, it is well to give the water at back and front, and make a few holes with a pointed stick over the surface instead of puddling the surface all over.

If I knew better the conditions under which you are placed, I might be more particular, but attention to the above details will enable anyone to have Mushrooms in a cellar, if ordinary care be taken.

I will add, that mere slap-dash work is of no use in Mushroom-growing: the fresher the material, if you can prevent it heating too much, so much better for the Mushrooms; too much heat after spawning will render useless the best bed; too much dryness in the material will starve the spawn, unless there are free waterings, a rather difficult thing with beginners. Too much moisture in the materials will also kill the spawn, from being too wet. I have had fine beds in wet material by wrapping each piece of spawn in a handful of dry litter; this, however, is better avoided. Where droppings cannot easily be obtained, littery dung watered and worked until sweet, will grow first-rate Mushrooms, cased or not cased with horse droppings. On the whole, however, nothing beats horse droppings, and a little short litter to keep the droppings open; and the better fed the horses are, the more likely are the Mushroom beds to flourish.—R. FISH.

CYCLAMEN PERSICUM.

It may interest the lovers of Cyclamens to know how quickly they may be made to flower from seed. I sowed a packet of seed on the 26th of February this year, and my first Cyclamen was in bloom on the 12th of September. I raised more than a hundred plants from the packet of seeds, and the greater part of them are now showing flower buds. They have been kept, since sowing, in a Cucumber house until about a month ago, when the most forward were moved into a cool house. They have received no peculiar treatment, merely potting whenever they required it. The largest are now in 48 pots.—AN AMATEUR.

THE FLOWER SERMONS.—In the journal of September 22nd I find a communication by "A CONSTANT READER," page 225, in which he says that Jones, of Nayland, delivered some of

them, and that he would be glad to learn if either Jones' or any of the others' have been published. On referring to the works of Jones, of Nayland, eight volumes, Rivington, 1826, I find in vol. iv. sermon 1, "On the Religious Use of Botanical Philosophy," preached on Mr. Fairchild's foundation at the church of St. Leonard, Shoreditch, on 1st of June, 1784.—E. HURST.

STOCKS FOR APPLE GRAFTING.

"READER," page 243, inquires about various stocks. I offer my experience for what it may be found worth.

English Paradise, as far as I have been able to prove it, appears to me to be only the Barr Knot, and the French Paradise a *mélange* of sundries, two of which are varieties of Doucin—*i.e.*, the broad and narrow-leaved. The Stübert, *alias* Harvest Logging, Avant tout Léatif, and Dutch Creeper (?) is a very early Apple, often called in nurseries Dutch Cedlin, and is here in great request, although why, I am rather puzzled, as it is a very secondary sort—"soon ripe and soon rotten." None of the above are worth anything for growing healthy trees upon, and I may say the same of two kinds called the Broad and Narrow-leaved Nonesuch English Paradise; these grow the first-year's shoot well, but afterwards get so stunted as to be useless. "Amongst the faithless, faithful only" is the true Pommier de Paradis, or Malus præcox, from the Caucasian Mountains. This is a free-growing hardy stock, on which the Apple grows healthily, and bears abundant fruit of high flavour and enlarged size.

As to the Crab stock, so called, this is not raised from seeds of the wild Crab, as "READER" supposes, but is the produce of seed washed out of the pomace after cider has been extracted. The seed when sown and grown produces three qualities of stock—*i.e.*, the first culling, robust free growers, with strong roots, and fit to work orchard trees upon. The next, or second size, are nice finely-rooted plants fit for garden trees, of medium growth. The third, or small size, are generally surface-rooting stocks, fit to produce nice healthy free-bearing trees of a dwarf character. None of the above will produce fine fruit, and often not so fine either in size or flavour as the true Pommier de Paradis. I send you samples from Crabs, also from the Pommier de Paradis, to show the difference.

It must be borne in mind that Apples worked on the Pommier de Paradis require strong damp soil, and the same holds good with Pears worked upon the Quince stock.—JOHN SCOTT, Merriott Nurseries, Somerset.

LAPAGERIA ROSEA.

I HAVE now under my care, growing in a cool conservatory, and gradually covering a good portion of the roof, a plant of this fine greenhouse twiner. It came into my hands in 1865, and was then a plant about 18 inches in height, growing in a 48-pot. I planted it at the south-west corner of the conservatory, in a spot which gets some shade at the latter part of the day; and to receive the roots I made a small pit or tank, about 3 feet in length by 1 foot in width, and edged it with stone. The pit was made about 18 inches in depth, and one-third of it filled with brick rubble for drainage. The Lapageria was then planted in some bog peat, as spongy as I could get it, with which was mingled some rough sand. It soon began to grow, and flowered for the first time in 1868; since then it has bloomed yearly; and as the plant increases in size and strength, the flowers not only become more numerous, but larger and of finer quality.

My mode of treatment is as simple as it appears to be effectual. During the summer, at the growing season, I water plentifully; during the winter, when at rest, it is watered only occasionally—just enough to keep the soil moist. Occasionally I top-dress the plant with peat and sand as required; the constant watering during summer tends to wash away the soil from the roots. It is well to thoroughly top-dress at the beginning of winter, just as the summer supply of water is withheld; then the newly-added soil gets pretty well settled about the roots by the time growth commences in the spring.

I get a supply of flowers about nine months in the year; and it seeds freely, some of the pods hanging on the plant for a considerable time. The plant makes vigorous growth, and during the past summer has made shoots 16 feet in length. It has been in robust health, and made wood freely.

I find it necessary to shield the young growing shoots from the attacks of woodlice and snails and slugs. These young shoots

come up through the ground of a character similar to those of the Asparagus; and as soon as there is a slug or a woodlouse in the house, it will find its way to it, and eat away the tip of the shoots. If this happens, the growth of the shoot is checked directly, and it rarely if ever starts again. As soon as I perceive a shoot coming through the soil, I place a lamp glass over it, and keep it there till it has made sufficient growth to be out of reach of the foes.

I think a very pretty effect could be secured by blending the white with the rose-coloured variety in the interior of the roof of a suitable house. At present the former is very scarce and expensive; when it becomes cheaper, it will no doubt be grown as much as the other and older form.—GEORGE VEXNER, *The Grove Gardens, Hamwell.*—(*The Gardener.*)

ROYAL ASCOT GRAPE.

HAVING seen in THE JOURNAL OF HORTICULTURE that the Royal Ascot Grape has taken many prizes this year at various shows, and as it is again referred to at page 221, the following remarks may interest some of your readers.

Two years since I inarched Royal Ascot on Muscat de Sarnelle, growing in a ground vinery. This year I allowed it to bear eight bunches, which are now ripe. The ground vinery is 28 feet long. This year the young leading shoot is growing out beyond the vinery, and from it, for most of the way up, laterals have sprung, on each of which a bunch of Grapes appeared; all have been cut off but one, the berries of which are swelling rapidly, and should this fine season continue, I have no doubt they will ripen this autumn. The laterals growing on last year's wood were stopped three leaves above the bunches; during the summer young shoots sprung from the end of these laterals, on which bunches of Grapes came. They were again cut down to one leaf, but had I left the Grapes to ripen I should have had two bunches on the same lateral, one ripe, the other unripe, at the same time. This I consider one of the peculiarities of the Royal Ascot and worth recording, because Mr. Standish called this Vine a perpetual, and so it would be a perpetual if grown in Queensland or California, or in any country where there is no frost. The Vine came into flower a fortnight earlier than a Black Hamburg growing in the same border under another ground vinery with the same aspect.

The Royal Ascot is certainly a wonderful Vine to sprout and bear, a Vine well adapted to grow in any tropical country not too hot. Last year I inarched the Royal Ascot on a young Black Hamburg growing in an open border. On the shoot of this year's growth there is a bunch of Grapes now (28th of September), just colouring. The Vine is tied to a stake.—A. T.

MANAGEMENT OF CUTTINGS.

Is it right to allow cuttings to flag after they are taken from the plant? My gardener thinks so, but I think it is better not to allow them to feel the change more than can be avoided.—A. B.

[This is a question of some importance, and something may be said on both sides. In all milky-juiced plants and those that are very succulent it is often well to allow the cuttings to lie until the cut ends are dry. It is no bad plan in order to hasten drying and prevent the waste of juice, to stick the ends, as the cuttings are made, into fine charcoal dust. If allowed to bleed too freely the cutting is proportionably weakened, and the rooting process will be all the more languid. If such cuttings were inserted at once, the exudation of juice into the soil would afterwards be apt to make the bottom gangrene and decay. A dry base is therefore of importance in very succulent plants, but even then the drying should take place in the shade, and not in the sun, as the sun might parch and dry the part too much. Even in the case of succulent plants we never could see any benefit accruing from allowing the stems and leaves left to become wilted and flagged. We have seen whole bunches of cuttings of Geraniums made, and allowed to lie until the leaves left were all flagging. That such cuttings grow afterwards we know, because the juices and vital powers stored up are pretty good proofs against the unfair treatment given. In taking small side cuttings of such things we seldom considered any drying of the base necessary. In taking stronger, more succulent cuttings, if we deemed it advisable to let the cut end at the base dry for a few hours, we took care that the bulk of the cutting should not lose any of its juices, by slightly

sprinkling with water or shading the upper part of the cutting whilst the base was exposed.

Except in such cases, we should never think of drying the base of a cutting. Even in these cases we would secure the bulk of the cutting feeling as little as possible its severance from the parent plant. We know that many act differently, and allow the cuttings to lie a long time after being made, as if there were some virtue in this wetting and withering. They tell you that the cuttings strike root, and so they will in the case of things not easily killed, but it is in despite of, rather than as a general consequence of, the system adopted. In the summer and early autumn months you may plant a Geranium cutting, the stronger the better, full in the sun, and though the leaves will flag, the cutting will ultimately form roots and fresh leaves; but such a cutting will strike more quickly if put in a pot and placed under glass, and so top-sprinkled and shaded from strong sun that the leaves are never permitted to flag. It is true this coxing and nursing plan may easily be carried too far; too much closeness and too much shade will encourage the cutting to lengthen upwards, instead of rooting freely downwards, and hence the rough-and-ready system of planting at once out of doors is often as successful as when there is the above care carried to an excess of coddling. In all general cases we hold with you, that the cuttings cannot be too soon inserted when taken from their parent plant, and the less they feel the severance afterwards [the sooner will they strike roots.]

ABOUT POTATOES.

"MANY of them of good size, but very coarse," was the critical judgment lately passed upon a large collection of some fifty kinds of Potatoes that were staged at one of the meetings of the Royal Horticultural Society at South Kensington. This critique was just, but not sufficiently severe; for if it had proceeded to denounce in strong terms the far too prevalent practice of growing, and especially of staging for exhibition, the huge, ungainly, sunken-eyed, and altogether "coarse" samples of our noble tuber that some people seem to think the *ne plus ultra* of Potato culture, then would a service have been rendered to horticultural taste, and possibly our eyes might soon be rid of the sight of those ugly monstrosities ye call "exhibition" Potatoes. I do protest against the Potato being put on a level with Mangold Wurzel as a show-root, making size the criterion by which to judge of its merits. Nay, even in judging Mangolds some respect is paid to shape and outline; but a Mangold be it big, or little, is but a Mangold still; whilst there are Potatoes and Potatoes, the difference being just this, that whilst some are fit to go upon the table of an epicure, others are only fit diet for the pigs. The difference may be but trifling, but it is enough that it exists. If I were philosophically inclined, I might profitably moralise over the strange taste for mere size that seems to prevail among horticulturists. We have nearly gone mad in the pursuit of it in some things, and now find we have committed a huge blunder.

Big plants have had their day, and are now rather pook-pooked; big Cucumbers, also, are now looked upon as so much cattle-food by judges of taste; big Melons or other fruit must pass through the sharp ordeal of the flavour test; and so it is all through the piece. And now we have but to get rid of the strange anomaly of big Potatoes from our exhibition tables, and then we may well hope for the display in the future of such cultural results as shall both please the eye and delight the taste; and that such a reformation is near I have good reason to believe. Business pursuits took me a short time since to the classic regions of Oxford; and whilst there, how could I resist the temptation, so strong to me a "potato-ologist" (?), to drop in upon that celebrated cultivator Mr. Robert Fenn of Woodstock, and get a look at what he was doing in the way of raising new varieties, as well as note the results of his mode of cultivation?

Mr. Fenn is a strong advocate for what is known as the "ridge and trench system" of culture; which system, however, simply means that the ground, having been well prepared and manured during the previous winter, the line is laid down at intervals of 3 feet apart, the sets are then placed in a row alongside of the line, and about 15 inches distant from each other in the rows, and then the soil is thrown up over the sets with the spade, burying them to the depth of about 6 inches. Of course no earthing-up is needed, and the trenches in between are at any time available for the planting-out of winter crops. I have tried this mode of planting myself, on a

dry soil, during the past summer, with but indifferent results—that is to say, I obtained no greater produce out of a line so planted than I did from a line planted on the old method, and therefore I did not esteem the mode of cultivation a desirable one to follow. Naturally I felt desirous to note how Mr. Fenn's ridge-planted Potatoes turned out; so, when the inevitable refreshment had been partaken of, we turned out to the garden. He grasping his digging-fork with as much zeal and fervour as a soldier would his beloved rifle, and I, note-book in hand, to mark in permanent characters the results. But first I must state, to my great joy, I found Potatoes were grown both upon the ridge and the flat system in the old rectory garden at Woodstock; and after a fair comparison of the produce, we concluded that nothing was gained by ridging, as the crop in each case was about equal in a given length of row. The advantages of the ridge system appear to be two—first, a saving of seed; second, great convenience for putting out winter crops. The disadvantages are—first, more manual labour required in planting; second, a smaller crop from off a given space of ground. One thing, however, must not be forgotten. Mr. Fenn grows solely for comparison, and not for his own consumption, a few of the coarse, rank-growing varieties, of which we have far too many. His study and endeavour has long been to obtain sorts that produce but a medium green growth, and of such is the bulk of his crop; so that the necessity does not really exist for wide spaces between the rows, as the expansion of root fibres is pretty much regulated by haulm-growths. Hitherto, also, the grafting process has found in Mr. Fenn a staunch believer—not necessarily, however, in its capacity to produce great or beneficial results, but rather in its capacity to produce changes; and as I have not previously scrupled to express my doubts as to the results of any kind being obtained, the first thing to be done was to lift some roots of grafted samples, starting with Milky White, to show its natural character. We next lifted a root of the same variety grafted into a Fluke, and found the produce to be more rounded in form; there was a decided deviation both in shape and colour, the foliage also distinctly altered. Then followed Milky White grafted into Yorkshire Hero. Here the foliage presented a combination of both these kinds, but the tuber was decidedly indifferent.

Onwards, a handsome second early round of good quality was next raised, and was followed by the same variety grafted into Yorkshire Hero; that developed a later growth of foliage that was still green, and the tuber rather rougher and of coarser appearance, and showing no improvement. Yorkshire Hero grafted into Ouwards exhibited no change whatever.

Here we held a conference to discuss and compare notes; and this was the result of our conclusions: He to retain his belief in grafting, but that it produced in the Potato no beneficial results; I to forego my hitherto utter incredulity, and to recognise the principle of Potato-grafting, but with the belief that for the production of improvement in sorts thereby it was worthless.

Thus far we had cleared out of our way two important points of difference, and now turned to the more congenial, but not less interesting duty of lifting and taking notes of the seedlings and more recent kinds. I think we started with the Old Lapstone, the parent of a numerous progeny. Why, I was quite startled this year to note in my large collection how many of the sorts developed the Lapstone foliage, a growth that, once seen, can at all times be recognised—upright, stiff, with rounded incurved leaves—a most desirable sort of haulm to get to a good variety; but I fear that betwixt the sorts that now yield this form of foliage there is rather too much of the tweedledum and tweedledee difference. Here are a few of them: Lapstone, Haigh's ditto, Huntingdon Kidney, Rixton, Lady Paget, Pebble White, Crystal Palace, Ashtop Fluke (how Ashtop?), Daintree's Kidney, Yorkshire Hero, and Beaconsfield Kidney, which latter Mr. Fenn thinks, as I do, is just the old Pebble White, but having a rougher skin than the Lapstone. Mr. Turner's other new variety, Uoion, is an early round that closely resembles Walker's Seedling round in general features. The Waterloo Kidney, as usual, lifted a fine sample, and it is without exception one of the handsomest and best bred of the white kidneys that we have.

Now we come to one of Mr. Fenn's newest and choicest productions, the Rector of Woodstock, which is decidedly a good stock. It ranks as a second early, haulm of moderate growth, and turns out such handsome white round tubers, and (for we tasted them) of such excellent quality, that it must be pronounced in Potato circles a real acquisition. This Potato

has been the result of most careful selection, as some dozens of seedlings, all of the same family, were lifted, and all good, but the Rector was the best; and we were thus enabled to sign and seal Mr. Fenn's judgment, as well as that of the Fruit Committee of the Royal Horticultural Society, who last year awarded this variety a first-class certificate of merit. A fine seedling round, pink in colour, of handsome appearance and good cropper, is approved, and so is a handsome red kidney that is very promising. Then we came upon a batch of seedlings raised from that capital round variety Early Emperor, the pollen parent being Ouwards, and lift a red round, much like the Emperor parent, but it does not run out like that variety. This seedling was both handsome and prolific. Next was a pink round, much the colour of the American Rose. It was rough in skin, early, and handsome, and is named English Rose. This is a very promising kind also. A white round, with purple-blotched eyes, very handsome and promising, is next approved; and so is a peculiarly good-looking, rough-skinned red kidney, out of the same batch, that we dubbed Fenn's Bountiful, for it is a good cropper, and a real beauty. The last selected of this breed is a strong-growing white round, having pink eyes, which is very handsome, and will make a superb exhibition variety. One more seedling was from a cross between Shutford Seedling and Hogg's Coldstream. This was a fine white round that will by-and-by take a prominent place as a fine early. I think this is the one we dubbed, in a gallant spirit, Eliza Fenn, after Mr. Fenn's kind and hospitable better-half. Mr. Fenn grows altogether a large collection, having nearly all the best-known sorts that are in the market, and many of these also were looked over, but notes of them may well be left until some other time, when I may also embody with them mention of the results of my own trials. I must, however, not omit to bear witness to the great care and patient attention that Mr. Fenn bestows upon the culture of his favourite esculent, as also upon the still more difficult duty of selection. A high appreciation of beauty in shape and outline perfects his judgment; and so much did the handsome and almost perfect form of many of his new seedlings impress me, that when the next day, on passing through Reading, I looked in upon the show then being held, I became so shocked with a sight of many of the big, coarse, ugly Potato monstrosities there staged, as to have suffered for some time afterwards from Potato nightmare. I exhort people who will show Potatoes, in the future to have some regard for the outraged sensibilities of Potato critics.

Years ago, long before Moule's system of earth closets had been unearthed, Mr. Fenn put the system into operation at Woodstock. I saw his *modus operandi*, and can vouch for its simplicity, originality, and effectiveness. This is the source from which is obtained the manure that has for some years grown the Woodstock Potato, and capital stuff it is. The best time for its application is early in the winter, and then it becomes thoroughly incorporated with the soil. It, moreover, keeps the soil light and porous, and is altogether exempt from most of those objections that apply to other strong manures when used for Potato culture.

Mr. Fenn has three specialities, in each of which he is well posted—viz., Potatoes, Bees, and British Wine-making. Of the first I have written; of the second, I can only say that his hives are of the best design, full of busy bees, and that his honey is delicious; and of the third—well, readers should see and taste for themselves who can. The fine old rectory-house has its entire front enveloped with Grape Vines that are bearing, goodness only knows how many bunches; but we saw that on one chimney only there must have been at least half a hundred-weight of fruit; and then there is a large portion of garden-wall also covered with Vines, and from the entire produce I suppose will soon be brewed wine enough to fill the large cellars under the rectory-house.

Some day or other, perhaps, the Potatoes, Bees, and Wines will make a noise, for Mr. Fenn has a right to look forward for the fruits of his labours. May the kindly geniality of disposition that so strongly permeates the character of our Woodstock friend always be his! and when once more he shall shoulder the fork and go forth to his annual Potato harvest, may I be there to see!—SOUTHERN.—(*The Gardener.*)

VINE LEAVES AS FODDER.—The *Chemical News* quotes from *Les Mondes*, to the effect that Vine leaves and the cuttings of young Vine twigs are largely given in France to cattle, in a fresh state, and are also partly salted for winter forage. Since

France possesses 2,500,000 hectares of vintage ground, this new utilisation of material will furnish food for a great number of cattle.

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 5TH.

THIS was one of the most crowded meetings ever held at South Kensington. There was a fair display in the floral department, a large and excellent display in the fruit department, but, after all, the great attraction, there can be no doubt, was the exhibition of Fungi. Round these during the afternoon the visitors flocked, and it was only with great difficulty that a glance of them could be obtained. The value of Fungi as an article of food has never yet, save by a few, been fully recognised. They are rich in that most valuable constituent of all articles of food—nitrogen, that constituent which least abounds in the food of the people, that which is the most nourishing, and that which is also in many of its combinations the most poisonous. For this reason Fungi, with the exception of the common Mushroom, the Truffle, and the Morel, are ever looked upon with distrust, and justly so too, for even some of those best acquainted with the family have made mistakes which have nearly had serious consequences; but there are many species with well-marked characters—characters which cannot readily be mistaken when once known—that might be utilised as articles of food by those who seldom taste butcher's meat—and their number is too many—besides being dainty morsels for the rich. But, as Mr. Wilson Saunders well remarked, we must educate the eye to distinguish that which is wholesome from that which is unwholesome, and there is no better means of doing so than exhibitions such as that we now record; and it is only to be regretted that all who came to see, from the very fact of their number, could not see so well as it might another year be arranged that they should see. The table on which the Fungi are arranged might be so placed that it might be inspected from both sides, instead of from one only, and it might be stipulated that after the close of the meeting the exhibitors should not at once carry off their collections without affording the visitors a chance of inspection.

Prizes of £2 and £1 were offered for the best collection of edible Fungi shown in Class 1; and a prize of £5 was offered by W. Wilson Saunders, Esq., F.R.S., for the best collection of edible and poisonous Fungi arranged separately. There was no exhibition in Class 1, but there were three collections shown in Class 2. The Judges decided on giving equal first prizes of £3 to Worthington G. Smith, Esq., and Mr. English, of Epping. Mr. Smith's collection contained of *edible* kinds:—Fistulina hepatica, or the Vegetable Beefsteak, Agaricus Prunulosus, A. pantherinus, A. rubescens, A. grammopodius, A. procerus, A. nebularis, Boletus scaber, B. edulis, and Lactarius deliciosus. *Poisonous* kinds:—A. phalloides, A. muscaria, A. melleus, A. squarrosus, A. fascicularis, A. sinuatus, Russula rubra, Lactarius controversus, L. vellereus, L. torminosus, Boletus luridus, Cantharellus aurantiacus, and a few others. In addition Mr. Smith exhibited a number of Fungi not known to be either edible or positively poisonous. Mr. English's collection consisted of *edible*:—A. melleus, Prunulus, campestrius, nebularis, personatus, rachodes, Boletus scaber, B. edulis, Fistulina hepatica, A. nebularis, Russula alutacea, Hydnum repandum, Amanita rubescens, Marasmius oreades. *Poisonous*:—Amanita muscaria, Boletus horvius, Lactarius vellereus, Amanita phalloides, torminosus, Amanita pantherinus, Russula rosacea, Pholiota squarrosa, Polyporus rufescens, Boletus luridus, Tricholoma nudus, &c.

The second prize went to G. W. Hoyle, Esq., and Mr. Austin, Reading, for about sixty species, many of the specimens of which were very fine. Mr. Orchard, gardener at the Priory, Wimbledon, sent a beautiful specimen of Hydnum coralloides, found growing on an Ash; and Messrs. Cripps, Tunbridge Wells, a fine specimen of Merulius lacrymans, the dry-rot Fungus, which will be alluded to hereafter. Messrs. E. G. Henderson & Son had a fine dish of Agaricus comatus.

FRUIT COMMITTEE.—G. F. Wilson, Esq., F.R.S., in the chair. Mr. William Paul, Waltham Cross, again sent examples of his seedling Grapes, which, however, the Committee failed to appreciate. W. Looke, Esq., Cleve House, Seend, Wilts, sent a curious sport from the Muscat Citronelle Grape, which is a small white one; some of the berries on the bunches were black, some white, and some striped black and white. Mr. Bogue, gardener, Gorhambury Park, St. Albans, sent a bunch of a seedling black Grape, which was not considered of any merit. Mr. C. T. Wells, Southend, Essex, sent two large baskets of Muscat Hamburg and Black Hamburg Grapes grown in his ground vinerias. The Grapes were of excellent flavour, and were awarded a special certificate. Mr. J. Colborn, gardener to J. Blyth, Esq., Woolhampton, sent some fine large examples of Salway Peaches, which were awarded a special certificate. Mr. Prentice, gardener to the Earl of Lichfield, Shugborough Park, Stafford, sent beautiful examples of Barrington Peaches, which, however, had but little flavour. Mr. Cornford, gardener to H. Streetfield, Esq., Chiddington, Kent, sent excellent examples of Walbrton Admirable Peaches, which were awarded a special certificate. Fair examples of Late Admirable Peaches were likewise shown by W. Dodson, Esq., Wilderness Park, Sevenoaks.

Mr. Thomson, gardener to Mrs. Dixon, Stanstead Park, sent good examples of Black Hamburg Grapes grown in an orchard house.

Mr. Foster, Pillington House, Leigh, Essex, sent large fruits of the Salway Peach, but quite unripe. Examples of Madresfield Court black Grape were sent from the Society's garden, Chiswick, and met with the high approbation of the Committee. A dish of Fig Mouso bianco, a green-skinned sort with a deep red flesh, and of most excellent flavour, was also sent from Chiswick.

Messrs. Rivers & Son, The Nurseries, Sawbridgeworth, exhibited an interesting collection of small Apple trees on the Noneseuch Paradise stock, heavily laden with fruit, and of very fine quality; a special certificate was awarded. Mr. H. Moore, Bradley Green, Congleton, sent examples of some seedling Pears, which were not considered of any particular merit. Mr. J. Dennis, gardener, Dresden, near Longton, Staffordshire, sent a small seedling russet Apple. Mr. J. Wade, gardener to W. Napier, Esq., Ardmore Lodge, Isleworth, sent some fine examples of Callini and Gloria Mundi Apples. Mrs. R. C. Haase, Addison Road, Kensington, sent some splendid examples of Blenheim Orange and Allington Apples, for which a special certificate was awarded. Mr. Cornford, gardener, Chiddington, Kent, sent a collection of six sorts of Apples of high merit, for which a special certificate was awarded. Mr. Garland, gardener to Sir T. D. Ackland, Killerton, Exeter, sent an example of Doyenne du Comice Pear, weighing 1 lb. 4 ozs. Mr. Beech, gardener to the Marquis of Northampton, sent some curious malformations of Manks Codlin Apple. Mr. Fenn, Woodstock, sent a pie, made of his grafted Ribston Pippin Apple, which proved rather flat.

Messrs. Cripps & Sons, nurserymen, Tunbridge Wells, sent a dish of Surpris d'Automne yellow Raspberries. From Mr. Dancer, Chiswick, came examples of Sandall's Late Plum. Mr. J. Welsh, Holley Combe, Liphook, Hants, sent an example of Prince of Wales Melon, which proved of fair quality. Mr. Heath, Newton Lodge, Middlewich, Cheshire, also sent a seedling Melon.

Mr. Scott, nurseryman, Crewkerne, Somerset, sent a splendid collection of one hundred and forty sorts of Pears, all very correctly named, for which a special certificate was awarded. Mr. Hepper, gardener to C. P. Millard, Esq., The Elms, Acton, sent a dish of Tomatoes of enormous size, for which a special certificate was awarded. Messrs. Carter & Co., High Holborn, sent a very large and fine collection of Gourds, Potatoes, Carrots, Beet, &c., for which a special certificate was awarded.

On this occasion prizes of £3 and £2 were offered by the Rev. G. Kemp, for six bunches of Grapes grown in the open air without protection. The first prize was awarded to Mr. Hepper, gardener to C. P. Millard, Esq., The Elms, Acton, for fine and well-flavoured examples of the Royal Mascadine. To Mr. J. Norris, Francis Court, Broadclyst, Devon, was awarded the second prize for good bunches of the same variety. This class was exceedingly well represented, many of the Grapes shown being well-coloured and possessed of good flavour. Amongst the most meritorious may be mentioned large and well-coloured examples of Black Hamburg, sent by Mr. W. Wood, High Street, Ewell, Surrey; also large bunches of the same variety from Mr. Davis, gardener to P. Ganley, Esq., Roehampton Park, Surrey. Examples of Royal Mascadine came from Mr. Garland, gardener to Sir T. D. Ackland, Bt., Killerton, Broadclyst, Devon; from Mr. J. Trauter, Upper Assenden, Henley-on-Thames; from Mr. Miller, gardener to J. T. Friend, Esq., Northdown, Margate; Mr. R. Lloyd, Brookwood Asylum, Woking; Mr. W. Earley, Digswell, Welwyn; and Mr. Gayton, Chesham. Good examples of Bidwell's Seedling and West's St. Peter's were sent by Mr. W. White, gardener, Crossmead Gardens, near Exeter.

By the Society prizes were offered for a collection of Black Grapes, a collection of White Grapes, a single bunch of Black Grapes, and a single bunch of White Grapes. For a collection of Black Grapes Mr. Bannerman, gardener to Lord Bagot, Blithfield, Rugeley, was awarded the first prize for fine examples of Black Hamburg, Lady Downe's, Gros Guillaume, Mrs. Pince, Alicante, Black Prince, Blithfield Seedling, and West's St. Peter's. Messrs. Lane & Sons, Great Berkhamstead, were placed second with very fair examples. For the collection of White Grapes Mr. Douglas, gardener, Lovford Hall, Ilford, Essex, and Messrs. Lane & Son, were placed equal second, the first prize being withheld.

For the best single bunch of Black Grapes Mr. Mattam, gardener to C. Longman, Esq., was first with a splendid example of Black Alicante. Mr. Laytham, gardener to Messrs. Bertram & Roberts, Rockhills, Sydenham, was placed second for the same variety, a fine large bunch. For the best white bunch Mr. C. Turner, Slough, was first with a remarkable example of Muscat of Alexandria, perfectly ripened; and Mr. Mattam second with the same variety.

FLORAL COMMITTEE.—Mr. J. Fraser in the chair. Mr. William Paul sent a remarkably fine collection of Tea Roses, the majority of them in 6 to 9-inch pots. These were in beautiful bloom, and this for the third time during the present year. Souvenir d'un Ami and Madame Willermoz were very fine; and conspicuous among the others were Madame de Vetry, Jolie Mansais, Madame Maorin, Maréchal Niel, Madame Falcot, and Vicomtesse de Cazes. To these reference will be made hereafter. A special certificate was given. Mr. W. Paul also sent boxes of cut blooms, which were fine for any season, and particularly so for the present advanced period of the year. Maréchal Niel, Souvenir d'un Ami, and Bongere were very beautiful, and Madame Falcot and Madame Pauline Labonte were also noticeable as forming richly-coloured masses. A special certificate was awarded.

From Messrs. Veitch, of Chelsea, came a collection in which were several fine specimens of *Odontoglossum grande*, *Cattleya Devoniensis*, *C. hybrida*, and *C. Dominiiana lutea*; *Rodriguezia secunda* with half a dozen racemes of its rich rose-coloured flowers; *Rhododendron Lobbiai* with splendid scarlet flowers; *Lienala spinosa* and *Corypha Martiana*, two handsome Palms *Bactris maraja*, *Calamns ciliaris*, a very graceful species, and a handsome seedling form of *Adiantum capillus-Veneris*. This was named maximum and received a first-class certificate, as likewise did *Platyterium alicorne majas*, and *Corypha Martiana*. A special certificate was given for the collection. Messrs. Veitch also sent a basket of *Retinospora obtusa aurea nana* with beautiful golden foliage. For this a special certificate was awarded.

Messrs. Backhouse, of York, received a first-class certificate for *Senecio argenteus* with handsomely-cut frosted foliage, and the same firm had a second-class certificate for a free-flowering variety of *Aster longifolius*, with bright rosy lilac flowers with a conspicuous yellow eye.

Mr. George, gardener to Miss Nicholson, Putney Heath, sent seedling *Pelargonium* Fred George, a well-marked kind. Mr. Peeke, nurseryman, Tunbridge Wells, also sent seedling *Nosegay Pelargonium*, and a seedling crested *Pteris*. Messrs. Cripps, Tunbridge Wells, exhibited a most beautiful crested form of *Pteris serrulata*, called *cristata magnifica*, forming elegant tassels, likewise a yellow variegated *Cyprinus Lawsoniana* named *lutea*, and a stand of cut blooms of hybrid *Clematises*, to show their value for late blooming out of doors. Among them were several very fine varieties.

From Mr. W. Moore, gardener to C. Leach, Esq., Clapham Park, came a splendid group of *Nerines*, including the brilliant scarlet *Nerine Fothergilli* major and *N. cousea* major, *N. humilis*, and several obtained by hybridising and by seed. A special certificate was given. Mr. C. Turner, of Slough, sent a basket of *Tricolor Pelargonium* Mrs. Healdy, with the leaves beautifully coloured.

Mr. Green, gardener to W. Wilson Saunders, Esq., Hillfield, Reigate, sent a most interesting group of *Orchids*, among which were the *Phloxia cristata*, beautiful but fugitive in its flowers; *Zygopetalum rosstratum*, with a large white lip veined with lilac at the base; a very singular *Epidendrum*, with pale green transparent flowers; *Stenia fimbriata*; *Epidendrum nocturnum*, with long tubular yellowish sepals and petals, and a white lip; *Nestrophin antennifera* and *Trichoceras parviflorus*, both with flowers of a singular character, those of the latter bearing a close resemblance to a fly. *Spiranthes margaritifera*, another singular plant, and several others were shown in this collection, for which a special certificate was given; and a similar award was made for *Miltonia Morelliana*, with very large flowers measuring 5 inches by 3½ across. Mr. Green likewise exhibited *Genera fulvida bicolor*, with brilliant scarlet flowers, white at the back of the tube and mottled with white in the throat. A special certificate was given to Mr. Deuning, gardener to Lord Londesborough, Grimston Park, for a magnificent specimen of *Dendrobium chrysothis*, a species noticed in our report of the last meeting.

Messrs. E. G. Henderson & Son, Wellington Nurseries, sent a collection of plants including several of those exhibited by the firm at the previous meeting, a brilliant group of the *Glyceria Lily* (*Nerine sarniensis*); a fine group of winter-flowering *Trees Carnations*, the pretty little golden-leaved *Thyme*; *Tricolor Pelargonium* Miss Goring, which received a first-class certificate; and *Pleroma macrantha floribunda*, with splendid violet flowers 3 inches in diameter. For this a special certificate was given, likewise one to the collection. Mr. Perkins, nurseryman, Leamington, sent *Sedum Fabarium purpureum*, which is the same as *Sedum spectabile purpureum*, shown by Messrs. Henderson. *Wigandia imperialis*, a noble plant for subtropical gardening, was also exhibited by Messrs. Henderson & Son, and had a first-class certificate.

Dahlia Monarch, a large and fine dark maroon self from Mr. Rawlings, of Romford, had a first class certificate, and a like award was made to Mr. Parker, Maiden's Green, Winkfield, for *Yellow Standard*, primrose yellow. *Prince Imperial*, buff, with a deeper-coloured centre, from Mr. C. J. Perry, had a second-class certificate. Mr. Harris, of Orpington, also sent several seedlings. Mr. Rawlings exhibited a stand of bouquet Dahlias.

Mr. Parker, Victoria Nursery, Rugby, exhibited *Ivy-leaved Pelargonium Golden Queen*, apparently a very vigorous-growing kind, with large leaves edged with yellow, and large flowers, white tinged with pink. This received a first-class certificate.

Messrs. Standish & Co. sent a collection of *Retinosporas*, among which were several variegated forms, the pretty *R. cricoides*, *R. leycopodioides*, and others. For this collection a special certificate was given.

GENERAL MEETING.—W. Wilson Saunders, Esq., F.R.S., in the chair. Several new Fellows having been elected, and the awards of the Fruit and Floral Committees announced, the Chairman called on the Rev. M. J. Berkeley to comment on the principal subjects exhibited, and particularly the Fungi. With respect to these he (the Chairman), said that such exhibitions were of importance, because the eye must be educated to distinguish the good species from the bad; it was of great importance to assure the public that the names given were correct, and it was only by the eye being made well acquainted with the forms and characters of Fungi, that it could be hoped to turn them to the use of the public generally.

Mr. Berkeley said before noticing the Fungi, he would first make some remarks on the plants shown. In the first place he would direct attention to *Dendrobium chrysothis*, a specimen of which was exhibited at

the previous meeting, but it was evident there was a great difference between it and *D. fimbriatum*, in the flowers being produced on a leafy stem, whilst in *fimbriatum* they were borne on a naked stem; there was also a considerable difference in the substance of the flowers. Several of the plants shown in Mr. Wilson Saunders's collection were then noticed, especially *Trichoceras parviflorus*, which, it was said, would be an admirable model for an artificial fly, which would prove "very killing." Messrs. Standish & Co.'s *Retinosporas* were then referred to as being most valuable Conifers, from their being nearly if not quite hardy, and it was mentioned that though in the midland counties *Cyprinus macrocarpa* had escaped the severe frosts of past years, at Chiswick a fine specimen 30 feet high had succumbed. A new wood from Panama, called the *Cordoba* (?), was then noticed as fine for cabinet work, but notwithstanding its high colour, it afforded no dye. Some specimens of the *Manks Codlin* were then shown. These came from Mr. Beech, gardener to the Marquis of Northampton, at Castle Ashby, and all of them were Siamese twins.

Coming next to the Fungi, Mr. Berkeley remarked that there was a beautiful specimen of *Hydnum coralloides*, which is extremely rare in this country. There was also a fine example of the dry-rot Fungus from Messrs. Cripps, of Tunbridge Wells. This was by far too common, and he would recommend its being committed to the flames as soon as the meeting was over, as there were probably hundreds of thousands of spores in the specimen. When the wainscoting was removed from the old Palace at Kew, there was a specimen of this many feet in diameter, which Sir William Hooker described as presenting a beautiful appearance. A saturated solution of corrosive sublimate was a remedy preventing the recurrence of the Fungus for years; but it appeared from experience with railway sleepers that those so treated did not stand so long as if creosoted. Among the Fungi exhibited there were some extremely rare, and some he had never seen before. *Agaricus melleus* was labelled both as edible and poisonous; though it was eaten in Germany, he had little doubt its use was often attended with fatal consequences. Another species exhibited among poisonous Fungi was *Boletus luridus*; now he had some time ago received a letter from Sir Walter Trevelyan, stating he was in the habit of eating this species; at first he (Mr. Berkeley) doubted this, but on specimens arriving in good condition he found that they were the genuine *B. luridus*. Other Fungi noticed were *Marasmius oreades*, which was one of the very best; the gills were far apart, pale, not brown; *A. nularis*; *Boletus edulis*, known by its mild taste, and the strong network on its stem; *A. orella*, and *A. Prunulus* (not *Badham*'s).

It was absolutely necessary that one should have some knowledge of Fungi before eating them, but the same applied to everything else; for example, the Water Cress, Horseradish, &c., for each of which Brooklime, Avonite, &c., had been mistaken. Mr. Wortington Smith had done much by publishing illustrations of edible and poisonous Fungi at a moderate price, and which were excellent guides in distinguishing the one from the other.

Mr. Berkeley then referred to Professor Huxley's address to the British Association at Liverpool, particularly in respect to spontaneous generation and to the influence of Fungi in disease. With regard to the supposed origin of cholera from Fungi, although there could be no doubt choleraic matter formed a far more favourable nidus for the low forms of life than healthy excretions, yet it was one of those things that had still to be proved, and that with great precautions. The prevalence of erysipelas in hospitals might not improbably be due to the gelatinous globules, similar to those seen on meat in an incipient state of putrefaction, being carried up in the atmosphere, and alighting on the wounds of the inmates.

The Chairman having proposed a vote of thanks to Mr. Berkeley, which was carried unanimously, called on Mr. William Paul for some remarks on the Roses he had shown.

Mr. William Paul said—The Roses before you are part of a collection which is intended to bloom from the present time to Christmas. They are all Tea-scented Roses, and this is the third time this year that they have been covered with flowers—first in May, again in July, and now in October. The flowers now out are but the beginning of the third series; the later buds on the plants will continue to unfold for a period of two or three months. The plants before you have been kept constantly under glass, although I do not hold this to be an indispensable condition of success. I have flowered Tea-scented Roses equally well out of doors up to this period, but from October onwards it is best to place them under glass, or the frost and probable rain may mar the beauty of the flowers, if it do not destroy them. Of all Roses the Tea-scented flower the most continuously and abundantly in the autumn and winter. The plants now exhibited were kept in a cold greenhouse during last winter, the frost barely excluded. They were pruned in January; and after the first flowering, which took place in May, was over, the flower-spikes were cut off, and the plants were rested by withholding water. A new growth shortly followed, producing the second flowering in July. The flower-spikes were again cut off, the plants again rested by the agency of drought. The third growth took place in August, and the commencement of the third flowering is now before you. These flowers are not so large as those previously produced, but they are valuable, and will become more so as the flowers out of doors grow less and disappear. In their future a little heat will be employed occasionally to mitigate the effect of the superabundant moisture of autumn and winter.

The next meeting was announced for November 2nd, on which day large-flowered and Pompon Chrysanthemums, berried plants in pots, Potatoes, and dessert Pears form the principal subjects to be exhibited.

THE WILLOW HERB AS A BEDDING PLANT.

WITHIN the present month we have seen used with excellent effect the common Willow Herb, *Epilobium hirsutum*. As a broad mass forming the centre of a large bed margined with a belt of something in contrast with it, it was very striking, and at a distance we concluded it was the Variegated Mint; on nearing it, however, and seeing its delicate pink blossoms (which, by the way, should not have been allowed to show), we recognised the pale form of this old acquaintance. For all the purposes for which the Variegated Mint is used this is equally valuable, and, we think, rather more effective. We had not before seen it used as a bedder, and as some of our readers may, too, be unfamiliar with its capabilities in that way, we think it well to take this opportunity of making them known.—(*Irish Farmers' Gazette*.)

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

LISSOCHEILUS KREBII (Mr. Krieb's *Lissocheilus*). *Nat. ord.*, Oreliaceæ. *Limn.*, Gynandria Monandria.—Native of Natal. Flowers yellow.—(*Bot. Mag.*, t. 5861.)

CALOCHORTUS LEICHTLINI (Max Leichtlin's *Calochortus*). *Nat. ord.*, Liliaceæ. *Limn.*, Hexandria Monogynia.—The genus was first brought to the front by David Douglas, one of the martyrs of botany, but his discoveries have passed away from our borders, but are now reappearing. The present species, entirely new, is a native of the Sierra Nevada of California. Flowers white, with a purple blotch adjoining the nectary.—(*Ibid.*, t. 5862.)

LEPTOSIPHON PARVIFLORUS var. ROSACEUS (Rosa-flowered *Leptosiphon*). *Nat. ord.*, Polmoniaceæ. *Limn.*, Pentandria Monogynia.—“A most lovely representative of one of the most variable genera of hardy annuals.” The flowers of this variety are of various shades of colour, from pale to deep rose red. Native of California.—(*Ibid.*, t. 5863.)

PASSIFLORA ARBOREA (Tree Passionflower). *Nat. ord.*, Passifloræ. *Limn.*, Pentandria Trigynia.—Native of dense forests in the mountain districts of New Grenada, Ecuador, and Venezuela. Not so beautiful as the commoner species. Flowers greenish white.—(*Ibid.*, t. 5864.)

CLUSIA OBOVATA (Sweet-scented *Clusia*). *Nat. ord.*, Clusiaceæ. *Limn.*, Polyandria Monogynia.—“An inhabitant of the volcano of Cherqui in New Grenada.” Flowers pink.—(*Ibid.*, t. 5865.)

BARLERIA MCKENI (Mr. McKen's *Barleria*). *Nat. ord.*, Acanthaceæ. *Limn.*, Diandria Monogynia.—Native of Natal. Flowers purple. The district in which this *Barleria* is found appears to be botanically little known, and to abound in novelties. Amongst others which Mr. McKen has procured are two magnificent Heaths, a *Phenix* different from *P. reclinata*, and some fine *Oreliæ*.—(*Ibid.*, t. 5866.)

LEPTOSIPHON ROSEUS.—This is the same plant as noticed above. “If an exception be made in favour of the admirable *Phlox Drummondii*, none of the annual *Phlox*works are more popular, or so well deserve popularity, as the plants included in the genus *Leptosiphon*. Of dwarf and compact habit, yielding profusely their star-like blossoms of various shades, and of the easiest cultivation in almost any soil, it can scarcely be a matter of surprise that they have from their earliest introduction taken place in the first rank. For twenty years the genus was represented in our gardens only by the well-known *L. androsæceus* and *L. densiflorus*, with their white varieties. To these were at length added the charming *L. luteus* and its variety *anreus*, both introduced by Messrs. Veitch, of Chelsea; and another, though it may be hoped not a final addition, may now be chronicled in the *Leptosiphon roseus*, a most charming plant, closely related in habit to the two last named, which it equals, if not exceeds, in beauty and in usefulness.

“This elegant and attractive little annual differs from *L. anreus* almost solely in its colour, which is a most pleasing tender rose, a shade by no means easy to represent adequately on paper. Like that of its congener, its habit is very dwarf, rarely exceeding 3 or 4 inches, with similarly palmate foliage, the flowers being produced in clusters terminating the stems and branches. The elongated corolla-tube, so characteristic of the genus, is fully three times longer than the limb, which is about three-fourths of an inch in diameter. In most of the specimens the rose-colour is uniform, but in some there is an approach to a stripe, or flake, which, however, in no degree

detracts from the appearance of the plant. Well-grown, strong plants will yield their flowers for several weeks in succession. To obtain specimens, however, that will give the maximum number of flowers, it is essential with this, as with the other species, indeed with all other annuals, to sow thinly, or to transplant the seedlings while young to such a distance from each other as will afford full space for development. When the same care and attention that are bestowed on bedding plants are given to the hardy annuals, then, and then only, will their capabilities be discerned.”—(*Florist and Pomologist*, 3s., iii., 217.)

AMATEUR MARKET GARDENING.

It has now become a fashion for persons with independent means to plant fruit trees and to sell their produce; a few words of instruction may not be amiss to such who take pleasure in fruit culture and yet wish to derive some profit from their gardens.

APPLES.—These should be grafted on the English Paradise stock (the French Paradise stock forms pretty trees for small gardens), and cultivated either as bushes or pyramids. They should be planted 4 feet apart in rows, and the central space between the rows may be cropped with light crops, such as Onions, &c., for six, eight, or more years, till the trees meet. Their pruning should be of the simplest; from the middle to the end of June every young shoot should be shortened to half its length, and towards the end of August all the young shoots that have put forth since the June pruning should be shortened to three leaves. In winter a few autumnal shoots will still be found that require pruning, these should all be shortened to three or four buds; and if the trees are aged and a little crowded with shoots, they should be thinned with a sharp knife, and this will constitute the whole of the pruning for the year. If the soil be rich the trees may be planted 6 feet apart, or if planted at 4 feet apart, every alternate tree may be removed and replanted in fresh soil at the end of ten or twelve years. In all cases the soil should be solid—i.e., not dug, and if the trees bear too profusely so as to exhaust themselves, some decomposed manure, about five bushels to 25 square yards, should be spread on the surface in winter and left there. I have commenced with Apples because they are the fruit of the people, almost a necessary of life.

CHERRIES.—Those of the Duke and Morello tribe may be planted as bushes and pyramids, 4 feet apart, with advantage if grafted on the Mahaleb stock. The Heart and Bigarreau Cherries, unless double-grafted, do not do well as pyramids in gardens.

PEARS.—These should be grafted or budded on the Quince stock, otherwise their growth is by far too vigorous; they may be planted as bushes, and nothing in fruit culture is more beautiful than a Pear tree the size of a Gooseberry bush full of large fruit; 4 feet apart for bushes, and 6 feet apart for pyramids will be perfect culture.

PLUMS.—Next to the Apple the Plum is the most valuable domestic fruit, for it may be pre-erred all the winter without sugar or any expense, till Plums are again ready. The trees may be planted 6 feet apart, and if, as is the case with some soils, they make a vigorous growth without bearing fruit, the trees should be taken up early in November and replanted in the same place. If large trees are required, pyramidal Plums may be thinned out so as to stand 12 feet apart; their produce here by this course is something to wonder at; my trees are twenty years old. Pruning in all these cases must be that recommended for Apples.

In these short and rough notes, I have given, I trust, enough to guide those who wish to make their fruit gardens profitable. The taste for good fruit is every year increasing, and it seems as if there would always be a profitable sale for healthy fruit. I have only to note that, in the first week of this month (August, 1870), from 1000 to 2000 bushels of my Early Prolific Plums could have been sold in Covent Garden at a remunerative price; we had not a full crop, but the few hundreds of baskets sent up made me wish for more. Those who would like to know a fruit salesman, may apply to Mr. John Black, Covent Garden Market.

A few words as to market-garden planting will, I think, do good, and I give them as axioms:—Do not plant many varieties but find out by trial—i.e., planting several sorts, one tree of each sort, and closely observe them, and if you find one or two or three sorts more prolific than others, plant from fifty to five hundred of such a sort. About thirty years since I found that one tree of Louise Bonne Pear bore a crop when some hundreds of sorts failed. Our plantation of this sort on Quince stocks, for fruit for market, is now 5000 trees. And again, my Early

Rivers or Early Prolific Plum is so popular, that our plantation of bearing pyramids is now nearly 5000. Of new Pears for market, Madame Treyve is a great bearer, and most excellent Pear; Beurré de l'Assomption is large and good; Beurré Bachelier, Beurré Clairgeau, Beurré d'Amanlis, and Doyenné du Comice are good market Pears. Of Plums, Prince Engelbert, Belgian Purple, Reine Claude de Bavay, Angelina Burdett, Early Orleans, and Belle de Septembre may be planted as pyramids 6 feet apart with great advantage. I ought to mention here, that my plantation of Apple trees 3 feet apart is now ten years old and in full bearing, as are my Louise Bonne Pears, five years old, also 3 feet apart.—(Extracted from *Messrs. Rivers and Son's Descriptive Catalogue of Fruit Trees*, 1870.)

GROUND VINERIES.

THE ground-vinery system is so full of interest in itself, and offers such important advantages to those who garden on a small scale—i. e., to the many, that I fancy you will be glad to give publicity to the following statement.

There are two plans of ground vineries now proposed for acceptance. One is the plan introduced to the public by Mr. Rivers in his "Miniature Fruit Garden" some years ago, in which he recommends a framework of wood or iron in the form of a ridge, and glazed with glass. This is placed on bricks, and the Vine is trained under it on a floor of slate. The other is Mr. Rendle's plan, which for the frame of wood substitutes his patent bricks. These are built up according to the method shown in his published engravings and directions, moveable squares of glass are employed to cover in the enclosed space, and the Vine is trained within, as in the former case.

I have employed the plan recommended by Mr. Rivers for growing Grapes for two or three years with very fair success; but having occasion to lengthen my vinery, and not being able to procure any more of the iron frames for glazing which I had hitherto used, I sent for some of Mr. Rendle's bricks. I have two Vines growing side by side, and leaving one under glazed iron-ridge frames, I constructed over the other Vine Mr. Rendle's ground vinery of bricks and glass.

During the past summer I have been able to test the merits of the two plans, and in the interests of amateur gardening I proceed to tell you the results of the trial. I found Mr. Rendle's plan in every way superior to that proposed by Mr. Rivers. There was, first of all, an earlier development of the leaf and flower in Rendle's vinery, and a greater uniformity of temperature. As the season advanced the texture of the leaf, and its colour so much superior to that of the other Vine, have been a constant object of remark by myself and all who have seen the Vines, and, as a consequence, the Grapes are larger, they have ripened earlier, and have a colour, bloom, and finish which I fancy it would be difficult to surpass by any other mode of cultivation. The Vines are Black Hamburgh, and the Vine which has done so well in the Rendle vinery did not, when the two Vines were grown under the glass ridge, ripen its fruit so soon as the other.

I think, therefore, we have here a very good test of the respective merits of the two plans. I have called these methods of cultivation (between which I have drawn a comparison) by the names of Rivers and Rendle, not because there is any controversy between the two individuals as to the utility of their respective plans, but simply for distinction's sake. I know that Mr. Rivers thinks highly of Mr. Rendle's plant-protector system, and uses it.—W. E. CAPARN, *Draycot Vicarage, Weston-super-Mare*.

[Mr. Caparn sent us two bunches of Black Hamburgh Grapes; the berries on that labelled "Rendle" were larger, better coloured, and sweeter than the berries of that labelled "Rivers."—Eds.]

POMOLOGICAL GLEANINGS.

ECKLAND VALE APPLE.—Who can tell us the origin or the history of this Apple? During a short tour amongst the gardens of Ireland lately, the Apple which above all others attracted our attention, and which there seemed the most general favourite, was that called Eckland Vale. Its great size, its clear, handsome appearance, and its great productiveness on young trees and on old trees in almost every garden we visited, were very marked. The name was new to us; the Apple, however, had a somewhat familiar look, as if we had known it before under another name, yet never have we seen it, or one like it, so beautiful and fine as we found it at Mount Merrion,

near Dublin. Specimens before us now, which we picked at random from a small tree in the gardens there, are very large, upwards of 4 inches in diameter, rather flattened, or what we would call of the Pippin shape, slightly angular. The eye is large, pretty deeply sunk. Stalk deeply sunk also, about half an inch in length, the end just level with the base of the fruit. Colour pale greenish yellow, slightly flushed with crimson on the exposed side, and having a few small ferruginous specks over the surface, with a slight patch of russet near the stalk. The flesh is whitish, rather soft and light, not evidently intended to keep long, briskly acid in flavour, and delicate in texture. This is an Apple which, when cooked, will dissolve very rapidly and completely, thus fixing its place as a very excellent early autumn sauce Apple.

Brockworth Park Pear.

In the colouring of the fruit and some of its features it is very similar to the Wormsley Pippin and Stirling Castle. It differs from the Wormsley Pippin in having acid instead of sweet flesh, and in the stalk, &c.; and from the Stirling Castle it is likewise distinct. Some of the paler specimens resemble Small's Admirable, but it is not that. It was sent out, we are informed, from one nursery in this country a few years ago as Prizetaker, but that was merely a name adopted for trade purposes. In the gardens around Dublin it was said to be a Scotch Apple. At Belfast we were told it was an Irish seedling raised in that neighbourhood. Will some one clear up the mystery? Here is an Apple quite unknown in the London markets, but which would fetch the highest price in its season, and by its exceeding productiveness would well repay the grower.

BROCKWORTH PARK PEAR.—In September we are already so

well supplied with good and useful Pears, that new varieties seem scarcely to be required. It would appear, however, that good as our supply may be, and satisfied as we have been, there is yet room for improvement—yet room for another good Pear, Brockworth Park.

This is an English seedling, and far in advance of nineteenth-century continental trash which is year by year forced upon us. It is, indeed, a first-class Pear, and the standard is now placed high. It has been awarded a first-class certificate by the Fruit Committee of the Royal Horticultural Society. At the first glance it greatly resembles a pale Louise Bonne of Jersey. The fruit is large, pyriform, rather bulged in the centre. Skin smooth, pale yellow, slightly flushed and streaked with crimson on the exposed side. Eye small, close, segments of the calyx pointed, set in a shallow basin, the end of the fruit being frequently blunt. Stalk about an inch long, stoutish, obliquely inserted without any depression. Flesh white, delicate, buttery and melting, very juicy, rich, and vinous, exceedingly pleasant to eat, greatly resembling in texture the well-known Marie Louise. This we welcome as a valuable addition, and congratulate the raiser on his success. We believe it will be sent out by Messrs. J. C. Wheeler & Son, of Gloucester.

THE DODDERS.

LAST week the Dodder plant was found growing luxuriantly on the Hop, in this parish (Lamberhurst). It appeared to me to be the same variety that attacks the Clover. I am not aware that the Dodder has been found before as a parasite on the Hop, and there has been no Clover near the field in question for some years.—W. C. MORLAND.

[We have received another query relative to the Dodder, our correspondent asking, "Is there more than one kind of Dodder, or is the Dodder which I have had on my Parsnip crop here (Jersey), the same Dodder that attacks the Clover?" So far from there being only one, there are at least fifty known species of Dodder, *Cuscuta* of botanists, and all of them have been well described as "plants like fine, closely-entwined, wet catgut." The following is one of the more recently discovered:—

Cuscuta Californica, raised from seeds received from Mr. Hartweg, and said to be collected in fields near Sonoma, in California. This little parasite clings by its delicate thready stems to any branch or leaf within its reach. Its minute flowers are at first in close heads, but as it grows older they separate, and eventually form short loose racemes; their colour is white, and their smell very agreeable. Although Professor Choisy regards it as a true Dodder, it probably ought to con-

stitute a new genus; for it has but one style, the peculiar scales within the corolla of the genuine *Cuscutas* are deficient, and the upper part of the flowerstalk is fleshy and transparent. In the accompanying cut—1, represents a flower magnified; 2, a corolla laid open; 3, a pistil; and 4, a cross section of the ovary. The seeds should be sown along with those of some soft-

stemmed annual in pots; and when strong enough, and before it destroys the annual plant which it first grew upon, some softwooded shrub, such as *Lotus Jacobæa*, or *Pelargonium*, should be brought within its reach; it will soon adhere and grow freely upon it.

It is a free-blooming little parasite, more curious than ornamental.

The Dodder we have known on the Jersey Parsnips is the *Cuscuta epithymum*, or Lesser Dodder, and most frequents Furze and Heaths, but less frequently fixes on Thyme and some other plants. *Cuscuta europæa* is a much larger and more robust plant, having stout red stems, attacking especially the Flax crop, but it rarely occurs in England. Both species have been observed growing on Hop plants; and, in fact, if the seed of a Dodder be sown near any softwooded plants it will attach to them, and the juices of the Dodder partake in some degree of the qualities of the plants on which it is parasitical. The common name is thus explained in our "Wild Flowers of Great Britain:—"

"Dodder, the most common name in England, is derived from the Dutch and German name for the plant, *Dodern* or *Todern*. *Dodd* signifying a bunch; and *dot*, a tangled thread. Its ancient British name, *Cwlm y cadd*, tangle upon wood, and the French name *Goute de Lin*, a bit of flax, all refer to the form of the plant, which old Turner well describes as 'lyke a red harpe stryng, and it wydeth about herbes, folding much about them.' It is so destructive to the plants upon the saps of which it lives, that it has received the local names of Devil's-guts and Hell-weed."

WORK FOR THE WEEK.

KITCHEN GARDEN.

LET all *Asparagus* be cut down as soon as decaying, and the surface of the beds dragged off into the alleys with a rough rake or fork. The beds may have a slight salting at once, and decayed manure may be wheeled on them and spread as soon as an opportunity occurs. Pot and prick out sufficient *Cauliflower* plants immediately. A considerable quantity of *Endive* should be tied forthwith, in order to avoid any check to the heart through early frosts. All spare frames and pits should be taken advantage of. If they covered Melons or Cucumbers the haulm may be removed, and the strong *Endive*, half blanched, may be planted with good balls of earth as thickly as they can stand by each other. Do not, however, water them; if the soil is dry, so much the better. Make provision for protecting in frosty nights *Kidney Beans* in full bearing; their season may sometimes be prolonged for some weeks by averting a single night's frost. Continue to secure plenty of the August-sown *Lettuces*; an old frame or pit should be filled with the latest sowing. They may be pricked out as thickly as they can stand by each other, choosing small and compact plants. Let autumn *Lettuce* be tied up to blanch as soon as ready. Go over the *Sorrel*, and cut down all overgrown plants, to provide young leaves for winter supply.

FRUIT GARDEN.

The general impression among practical men is that autumn planting is superior to spring planting, and as an advocate of the former I would advise those who intend making new orchards, removing large fruit trees, or replacing decayed young ones, to commence preparatory operations immediately. In the first place secure fresh, sound loam, and if it can be obtained with some rough turf in it, so much the better; if not, it will do to mix rough stable litter, straw, or any other coarse material with the loam when filling it into the holes. The loam being provided, and thrown into a high and sharp ridge in order to throw off the rains, the next proceeding is to thoroughly drain the site intended for planting; without this all subsequent operations will only end in disappointment. Stations may then be formed by making a bottom of broken stone rubble, broken bricks, or other hard materials, placing a coating of cinders on this hard surface to prevent the soil from entering the porous materials beneath. As to depth, great moderation is advisable if the kinds are in any way tender and designed for the dwarfing system. For such, 18 inches in depth of soil will be sufficient, and if the ground is of a moist character, one-third of the bulk of soil should rise above the ordinary ground level; indeed, in all cases it is well to raise it considerably. A trench should be thrown out without delay round very large trees intended for removal. This will at once check late growth, and induce a disposition to produce fibres.

FLOWER GARDEN.

Trim and dress frequently during the decline of the season. Look well after choice seeds. Dablias should be earthed-up round the stems to preserve the crown of the root should any frost suddenly come. In consequence of the fine autumn a good quantity of seed will be gathered; choose a fine day, and cut that which is ripe: it may be gradually dried. Anriculas will require more attention now. Raise the frames on bricks, keep the lights off as much as possible, but always draw them over the plants in heavy or continuous rain. Plant offsets of Tulips as quickly as possible, and make preparations for planting the best beds towards the latter part of the month. All soft or diseased bulbs had better be planted forthwith. I fear many fine seedlings have been seriously thrown back, and in some instances wholly lost, by last season's blight, frost, and mildew. If the beds of Pansies for next year's blooming are not already made, lose no time in putting the plants out, that they may be established before frost comes. Take off all rooted layers of Carnations and Picotees, pot them in half-pint or pint pots, and place them in a frame for ten days.

GREENHOUSE AND CONSERVATORY.

Much has to be done in these and the other plant houses for the next fortnight. All pots should be washed clean and all insects extirpated. Should any plants prove so foul that some time must elapse before they can be thoroughly cleaned, they had better be removed to the plant hospital or some of the other houses where they will be out of sight and can do no mischief. Everything must now be made thoroughly clean, if success is to be obtained through the dull winter months. Above all things let the glass, both roof and sides, be washed; those who are unfortunately scant of labour cannot accomplish this, but the difference in point of success between a dirty roof and a clean one will be found enormous, all other matters being equal. Let everything liable to suffer from frost be housed immediately. A single night's frost will render nugatory the labour of many months. The tall Cacti should by this time have completed their growth; it is good plan to remove the terminal point from such as are still growing, and to diminish the supply of water; indeed, they will need very little, if any, between the end of October and January. Let them have abundance of light, which is of paramount importance in securing good bloom. Whatever watering may be necessary should be done early in the day, so as to allow of getting the superfluous moisture dried-up before night, for there is much more danger from damp among plants in flower at this season than from frost. Preserve a rather low temperature; and on cold, dull, cloudy days it will be advisable to use a little fire heat with air, so as to secure a moderately dry state of the atmosphere before night. Use fire heat very sparingly, however, and only when it may be necessary to prevent injury from damp, or to keep the temperature from falling below 40°. Where plants have been brought from warmer houses it will hardly be safe to allow the night temperature to average below 45°, but in houses containing a mixed collection of plants there is more danger to be apprehended from a high night temperature than from keeping it somewhat lower than may be suitable for some of the inmates.

STOVE.

The temperature of this house must, of course, decline with the decline of the year; as light is restricted, so, too, must be the heat. Continue to remove to a cooler house with less atmospheric moisture all Orchids which have thoroughly ripened their growths. The Cattleyas, when rooting freely, will continue to sprout buds from the base of the pseudo-bulbs if kept in constant excitement; this, although it increases the volume of the plant, robs the blossom. The *Aërides*, *Dendrobiums*, &c., will continue to enjoy a tolerable amount of both heat and moisture. In the growing or warmest house let 80° by day and 70° by night be the maximum for a week or two; for the other at rest, 65° by day and 60° by night will be sufficient.

FORCING FIT.

Frost may shortly be expected, and the pleasure ground and flower garden will then be stripped of its gay colours; how to preserve and encourage in doors a constant succession of flowers during the dull winter months becomes, therefore, an important consideration at this period. Part of this business may be accomplished by retarding autumn flowers, and part by genuine forcing. Success in the latter, it is well known, depends in no small degree on eligibility of the plants selected, as well as on the condition of the stock at the end of autumn. All plants intended for this purpose should have undergone a

preparatory course for weeks, nay for months, previous. An equally important concern is to provide a proper house or pit. In such a place three or four principles are of the greatest importance, and must be duly secured—viz., a sufficiency of atmospheric heat, a steady and permanent bottom heat of, as near as possible, 75°, plenty of atmospheric moisture at command, and abundance of light; in addition, a night covering would be a great acquisition. Those who cannot command such a perfect structure may resort to a pit heated by fermenting materials, the best and most enduring of which are tree leaves, more especially those of the Oak. Two-thirds of these, fresh from the trees, mixed with one-third of last year's stock in a half-perished state, and trodden firmly to the depth of 4 feet or more, will make a gradual and enduring warmth. A coating of tan may be placed over it for plunging. Some structure of this kind should be prepared as soon as fresh leaves can be obtained.—W. KEANE.

DOINGS OF THE LAST WEEK.

ANOTHER sunny week, but trying to most things not fully established. All the water we saved from the rains has been used-up for nearly a week, and but for the cooler, longer, and dewy nights we should be feeling very much the want of water. Partly owing to the heat and the dryness, we have been visited with clouds of *flies*. On the afternoon of the 28th ult. the air was filled with them. We could scarcely move without being covered, and eyes, mouth, and nostrils getting their share. On some places they formed large clusters like bees. The flies were about half the size of the common house fly, and brownish in colour. They have been more scanty since, though there were plenty of gnats and ephemeral flies that enjoyed their short existence in the sunbeams. It appeared, too, that in the afternoon numbers of the small greenish fly that have plastered the leaves of Turnips and Cabbages, rose on the wing for short periods. Altogether one might have supposed we were going to be visited with one of the plagues of Egypt. Every day we are reminded how dependant we are, and how even the most minute organisms and the smallest insects may render nugatory all our efforts. How soon the red spider and the green fly would, if left to themselves, leave little but a wreck in our vinerics and Cucumber houses! This season good fields of Turnips have here been the exception, not the rule; and even some of the best of these fields, after passing through the ordeal of possible attacks from the Turnip beetle and growing rapidly, considering the dry season, are now next to destroyed by whole clouds of a small greenish fly plastering the leaves. Caterpillars and a similar fly are causing sad havoc in the gardens in the neighbourhood, attacking everything of the Cabbage tribe and leaving little but weeks behind. A cottager told us lately that they had much reason to be grateful for the fine crops of early Potatoes, as they would be very expensive to purchase soon, owing to the devastations of the fly among the Greens of all sorts that would have helped in winter.

KITCHEN GARDEN.

Cabbages.—As already stated, we have scarcely suffered at all from caterpillars. Scotch Kale, Savoys, Brussels Sprouts, and Cauliflowers scarcely present a hole as marking where they had been present. All these, too, have escaped this little fly, though here and there patches are to be found. It has been worst on the young Cabbages just planted out and beginning to grow. The little point of growth in the heart and the smaller leaves round it would be covered with the flies, and these, if left to themselves, would soon suck out all the juices, and if the plant lived at all, it would either grow without a heart, or send up from the base two or three heads instead of one, and thus retard the time of cutting for use. By dusting, squeezing, and syringing with clear soot and lime water, we thought we had got rid of the intruders, but we find that others have come and taken their place. This week, too, many of the stumps of the Cabbages that were planted in the autumn of 1869, and which were looking so well, are becoming covered with these insects, and if let alone and no heavy rains come, they will soon be in as bad a plight as some of our best Turnip fields. We find that sewage water, if clear and not too strong, not only kills them but prevents them from coming. Even on young Cabbages it is quite as effectual as clear soot water. Fine soot is very good as a slight sprinkling. Neither that, however, nor the sewage water over the top or leaves would do where the vegetable was to be used soon afterwards.

It is always well to be learning even in little things, for, like

little insects, they may become of great importance. We have had no occasion to net from birds, game, mice, or rats seeds committed to the ground, since we dusted them with red lead. The most singular fact is, that hardly ever is a hole made to find out what like the seeds are. The instinct of the intruders seems to say to them, It would be dangerous even to hole the soil. So in the present case, could we do it without being uncomfortable to ourselves, we have a strong growing conviction that strong unpleasant scents would greatly deter our insect enemies from visiting us in their various transformations. It is often possible to secure a scent that would be distasteful to them and yet be encouraging to vegetation, such as placing strong soot water or other ammoniacal water in the evaporating pans of bothouses. The fumes of sulphur are as distasteful to many insects as they are to man, and if not presented too hot will do little injury to plants. We shall use the garden engine with not the most pleasant waters on our old Cabbage quarters, as we have enough to keep us going elsewhere until a cleansing rain shall come.

Potatoes should now be mostly out of the ground; and, especially where they are, owing to the dryness, taking a second growth at the roots, and are sending out fresh tubers from the old ones. The other day we saw young Potatoes as big as walnuts, some even as large as eggs, coming from the regular tubers, and these even not over-ripe. In all such cases the young tubers are waxy and watery, and the older ones are rendered hard and often stringy. It is best to take them up whenever this tendency manifests itself, as there can be no question the crop is otherwise greatly deteriorated in quality. In a few limited cases such an unfortunate occurrence may be turned to a beneficial result. For instance, we had lately sent to us a Potato plant of a late white kidney variety with seven or eight nice-sized tubers attached to it, and from each tuber there had come from one to three tubers from the size of marbles to that of walnuts. There were some six rows of 40 feet in length in this condition. As young Potatoes always brought a good price, especially after February, we advised to let them alone, merely giving them an earthing-up, removing the haulm as soon as it decayed, and covering the rows over with litter to exclude frost, and to dig out in spring for the new Potatoes. For private use such tubers, as now waxy Potatoes, could come in before Christmas, but old gardeners know that it is of little use to tempt with such things as early Potatoes until after the new year, or even till after parliament has met. Of course such Potatoes might not be so good as those grown during most of the winter in pits and frames, but having tried the plan several times they are very passable, and we should think much better than the old Potatoes which, it is said, are sometimes brushed and scrubbed to get the skin off, to look as if they were new and early. Our Potatoes have long been up; but if we had a few rows similar to those alluded to, we would have been tempted to let them remain in the ground until after the new year. In a similar case long ago we lifted the Potatoes in November, and put all the new growths in dry sand, and thus kept them until needed, but we did not think they were so good and sweet as those left as above on the plants during the winter. We thought them quite as good as the produce of Potatoes kept back and planted in the month of July. Of course it is only in a peculiar season that the tubers of the Potato put thus out the second growth of young tubers. Where the quality of the crop is considered the second growth should be avoided by lifting the crop earlier. There are still good breadths of Potatoes in the ground, and, less or more, these are attended with this second growth.

See last week's notes as to pricking-out Lettuces, Cauliflower, &c., and transplanting Lettuces half grown to where protection could be given to them. Sowed the last piece of Ruishees in an earth pit, so that a little protection can be given them if necessary by the end of the month. Forked in a dressing of lime in the ground intended for Cauliflower glasses, so as by frequent forkings to get all slimy enemies away. Earthed-up at once part of a Celery bed, it having been tied some time, and after watering with sewage, put a couple of inches or so of earth on some other beds to prevent the moisture escaping, except through the leaves, which it has done very rapidly of late. Before earthing-up, and as ashes at present are scarce, we strewed powdered lime over the bed, and threw it against the stems of the plants below the leaves, whilst these stems were damp with dew. This, as well as a little dusting of soot, will keep worms and slugs from rising and disfiguring the foot-stalks of the leaves. We have seen no grub in the Celery leaves this season, and we attribute that chiefly to the fact that the

little water we could give was from the house sewage, and to a slight sprinkling of soot over the foliage, which we think helped to deter the fly from depositing its eggs. Where the grub mines between the two skins of the leaf, and makes it alike a comfortable home and a rich dining place, there is no means of touching it there, and the only remedy is to crush and kill, or pick off the infested leaves and burn them. The Celery tied some weeks ago is now pretty well blanched at the centre. The tying also induces the centre to rise. As lately stated, much of our Celery has not been long planted, as we could not have watered it, but the plants were large, and with large balls, so that even for a day they scarcely felt the moving, and will come in before the earliest ones are used up. Thanks to shading, &c., though we could scarcely give any water, we do not notice a trace of a bolted head.

FRUIT DEPARTMENT.

Strawberries in pots for forcing we moved, so as to give more room to the large foliage, and thus help the ripening of the buds. Owing to the dryness we could not obtain early runners, but now the most of the plants are quite large enough to our taste. In moving, every vestige of a weed and runner was removed. No autumn could be more favourable for such plants, the bright sun beaming on them, and not a shower for more than a fortnight. By this time we have often had to turn the pots on their sides to prevent their being incessantly deluged. When such rains come in October, or the end of September, it would be well for the plants if we could take them under glass, so as to have an abundance of light and plenty of air. Few of us, however, are able to give them such good quarters. We have no doubt that many fine plants are injured by their being constantly wet, or when the pots are laid on their sides and are then struck with a sudden sharp frost, which affects the plants more than when the pot stood upright, as then the leaves would so far be a protection. We are quite convinced that many a plant that goes blind in the forcing house would have fruited but for the bad treatment it had in the autumn and early winter months. A plant exposed in a pit has a hard time amid changes of weather, temperature, &c., as compared with a similar plant growing in the open ground. It is difficult to know at times, with limited means, what to do with them. In the beginning of last winter we packed a great many pots with dry leaves in an earth pit covered with old sashes, leaving the tops of the plants exposed, and no place could have suited better, but the grass mice and rats were attracted by the mere protection, and, in spite of every scheme we could think of, they cleared out the buds of some hundreds of our best plants, whilst we do not think they ate a single bud of the plants growing in the ground out of doors.

Partly taught by the above circumstance, and partly owing to the wish not to have so many pots filled with Strawberry plants, thus saving the attention and labour requisite, we generally about this time turn out a good number of young plants into a piece of ground which has been well exposed to the air and enriched on the surface, planting them 6 or 7 inches apart, and raising them if we should want them in spring. Good runners planted out in September do very well for this purpose, but they do rather better, and are more easily managed, if before this planting-out they have made a little ball of roots in a small 60-sized pot. When planted out the fresh roots keep closer together, and the plants lift better for frames, pits, and for potting in spring. These do very well for the last crops in-doors when taken up about the end of March or the beginning of April. For all early work it is necessary that the pots should be crammed with fine healthy roots in September; in other words, that the plants be fully established in the pots before resting in the beginning of winter.

Proceeded with *gathering Apples and Pears*, and on the whole find them individually larger than we expected they would be. They swelled very much after the showers came, and now the bright sun is giving them a good colour. It is such a loss when good fruit drops; it seldom keeps any time, and always shows the blemish when cut or peeled. It is well to keep all fallen fruit by itself for earlier use. Such a plan would lessen the labour in a fruit room, where only the best fruit is placed. It is of little use storing up inferior fruit, which will have again to be shortly removed as useless. A few Pears on bushes are a little spotted this season, and housing what would not do even for stewing is of little use. Talking of stewing, a friend of ours mentioned the other day that the fine old stewing Pears seemed to be quite at a discount, which may be owing to the fact that our very best Pears when used when hard, before they begin to be the least mellow, turn out also the best when stewed.

Pine Apples grown by fermenting material should now have the linings well banked up, so that plenty of air may be given without lowering the temperature. Where fire heat is used there will be less difficulty. Those swelling will require a moist high temperature and more air as they approach ripening. Those intended for fruiting in spring should slightly rest, from having less water.

Late Melons must have a good temperature to swell them off, and if in frames will need the linings to be turned and banked up to the top of the frame. The same will apply to Cucumbers. Our first spring Cucumbers in a pit still keep on so well that we decline taking them out as yet, and, therefore, have turned out strong plants in a pit to give a late supply, and we will grow on in pots others to be turned out as large plants a month or six weeks hence, when the first alluded to are bearing. Winter Cucumbers, allowed to bear freely before Christmas, do not often bear freely afterwards.

Late Vines with the roots in borders out of doors will be the better of plenty of sun, but if heavy rains come they will do better if protected. Sashes raised above the ground would be best, waterproof cloth or shutters would be the next best. A makeshift may be made with rough covering, or roughly thatching with dry litter. See what was lately said about early-autumn planting. Vines, if the roots are protected from frost and wet, need be no exception to other deciduous plants. Early Peach houses may now be stripped of the leaves as soon as they ripen. If there is any spider or scale, it is advisable to syringe them well with soft-soap water, and clear soot and sulphur water. When clearing it is well to scrape off the surface soil, and to water through a rose with water near the boiling point, if the nearest roots are from 2 to 4 inches from the surface. The water will be cooled before reaching the roots, whilst any insects or eggs near the surface will be destroyed. Before colouring walls it is well to wash or syringe them and all woodwork freely with the hottest water. Every chink and cranny is apt to be a depository for insects and their eggs, and a little care in the way of prevention will always be better than getting rid of them when the crops are growing.

ORNAMENTAL DEPARTMENT.

The flower garden is still fine. Verbena beds are again, after recovering since the rains, feeling once more this sunny fortnight. Where water is as scarce as with us we would not advise planting many Verbenas. Ours were very good and most useful for cut flowers before the drought came, and then no mulching, &c., could keep them vigorous. A good watering once or twice a-week would have preserved them in health and bloom, but that we could not give them. All the varieties of Geraniums stood the weather well. We have had better beds during the season, but perhaps the best we have now after the second drought are two companion beds of Punch, which are one mass of brilliancy, and could scarcely have been excelled in the middle of August. Rubens, a favourite pink of ours for autumn, is good still, but some of the petals are bleached a little by the slight frosty mornings; as yet, however, we have suffered little. Even Calceolarias, passable in June, have rich masses of colour. To keep the beds somewhat in character we have cleared off the leaves of deciduous trees which had fallen, so far marring the effects of the flowers and rich green lawns, though in a few places feeling the effects of this bright weather. We shall not yet think of moving anything from the beds. We are still busy propagating, giving the cuttings a little heat. The first-put-in are hardening-off, and the intermediate ones have had the shading removed. We would give little shade to flower-garden cuttings if we had clean water to give more frequent dustings overhead from the syringe. From reasons previously detailed, taking small cuttings involves a little more care than if they were larger. We gave manure water to Salvias, Chrysanthemums, Geraniums, and large-flowering Pelargoniums intended for late blooming in pots, and kept potting and repotting Cinerarias and Primulas. We shall have some trouble with Violets, as from the dryness they were much infested with red spider in summer; Neapolitans suffered most. They are becoming better now from syringing. Plenty of flowers are coming on others, single and double.—R. F.

TRADE CATALOGUE RECEIVED.

W. Clibran & Son, Millbank Nursery, Warrington.—Catalogue of Dutch Flowering Roots, Roses, Pelargoniums, &c.

TO CORRESPONDENTS.

* * We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By doing so they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

BOOKS (R. F. Y.).—We never saw a separate copy of Abercrombie's "Seed Estimate." It was appended to one of his larger works, and they are long out of print, except his "Pocket Journal" and "Every Man His Own Gardener."

NATURAL ROCKS (J. E. W.).—We do not know of a vendor anywhere.

HEATING BY GAS (P. S.).—Procure No. 341 of this Journal. You will find in it engravings of gas stoves. If the house is large it will be more economical to have hot water or a flue, in the absence of definite information as to dimensions, &c., it is impossible to advise.

WHITE DOUBLE GERANIUM (H. Rising).—We have heard of but not seen one.

MARKETING FRUIT (F. P. G.).—If the fruit is of such good quality as you state, apply to Messrs. Webber & Co., Central Avenue, Covent Garden Market, London. As you live so far from town, the cost of carriage may render it more remunerative to dispose of your surplus produce in some market near home. The problem which you propose—to dispose of produce to the best advantage—is one which admits of a variety of solutions according to circumstances.

LAWN SAND (A. C.).—We know nothing about the article, and feel certain that no application which will destroy weeds will at the same time benefit the grass.

PRIVET EDGING (W. R. H.).—Privet would no doubt grow, but we think it would not be easily restrained even by the shears. We have, however, seen it kept neat at a height of 1½ to 2 feet, but that is much too high for an edging. Have you tried Ivy? We have seen it used with good effect. The small creeping kind of the woods is best.

PRUNING VINES (Young Beginner).—We have no fear of the mode of pruning you have been advised to adopt answering well, but we do not think it necessary with Vines so young as yours are; and the bunches from the large eyes, though larger, are often loose, and for many other reasons are not equal to those shown by the eyes at the base of the shoots; besides, you will have shoots that must crowd and interfere with the bearing shoots, therefore we should prune to two eyes, and, rather than have another shoot several inches above it, we would let one of the two shoots that come from the eyes be for wood, and the other for fruit. But even that is needless. One good shoot is enough for each spur, and retain as many spurs as can have proper exposure to light and air. It often happens when the system of pruning advised is adopted, that the eye left to form wood for another year's bearing does not break, or not strongly, and you have, as a consequence, an ugly bare length of spur, which it would require nearly a dozen years to form by the other mode of pruning. Your Vines have done well this season. Would it not be prudent to let well alone? We think, however, that you crop them too heavily.

GRAPES FOR LATE-HANGING (T. H. D.).—For hanging well the Madresfield Court Muscat is unequalled. We should have at least two of it, White Lady Downe's, and Trebbiano. They do not require more heat than Lady Downe's.

VINES (J. Leonard).—If there is a succession rod to take its place, you may cut out the old rod which has borne.

GRAPES SPOTTING (Allan).—We think your Grapes are affected with the spot, and in your case it appears to be caused by syringing after fumigation; besides, we do not approve of Vines, of which the fruit is not ripe, being kept without water for the last two months. That would cause them to go off as you describe when the weather became moister. The border ought to have had a good watering within the last fortnight, for in a dry border Muscats do not ripen well; indeed, to do them justice they require a good deep border, and an abundance of moisture while swelling the fruit.

HEATING A VINE BORDER (A. Clapham).—We should think that three 5-inch pipes would be ample. The size of your chamber is of less consequence than having the pipes not far from the covering, whether of stout slate or flagstone from 1 to 2 inches thick. At page 251, second column, you would see how you might rough-chamber such a place with clinkers or brickbats, but not covering the pipes deeply, and then have some fine gravel on the top. On that over the chamber you would require from 10 to 25 inches of good soil, and a fourth of equal parts of lime rubbish, bruised hoiled bones, and a little half-rotted manure well aired and dried, so as to be free from fungus spawm. Of course, if you use four pipes in the border you will have to heat them less. We are in doubt if we quite understand your object.

VARIOUS (Amateur).—Put in some buds next July on the bare portion of the stem of your tree, or cut it back to the lower portion. Place the glass covering over your Strawberries about the beginning of the year. Get your Peach tree into better health, and treat it well. Your fruits may have dropped through dryness at the roots, or too much vigour, or various causes which we cannot even guess at. Spur-in all the side shoots on your Currant trees pretty closely, leaving a framework of five or six branches only, and stop the points to one-half their length. For Gooseberry bushes leave more young wood, but thin the centre considerably.

EXHIBITION STANDS FOR ROSES AND DAHLIAS (E. M.).—The boxes may be made of inch deal, and the length for twenty-four Roses should be 4 feet; for eighteen, 3 feet; for twelve, 2 feet 2 inches; and for six, 1 foot 6 inches. Breadth in every case 1 foot 6 inches; height at back, 6 inches; height in front, 4 inches. We extract the foregoing dimensions from the excellent "Book about the Rose," by the Rev. S. Reynolds Hole, who adds:—"The covers, being 7½ inches in depth at the back, and 5 inches in front, 4 feet 1 inch in length, 1 foot 7 inches in breadth, and having a narrow beading within the four sides, half an inch from the bottom of the lid, overlap the boxes, leaving ample room for the Roses, and are secured for travelling by stout leather straps. Within the boxes some exhibitors have laths pierced at equal distances on a uniform surface of wood; but as Roses differ in size it is more convenient to have the facility of placing them where we please, and for this purpose it is desirable to have strong laths ¾-inch in depth, and 17½ inch in width) extending the length of the box. These laths should be six in number, and should be nailed on two strong pieces of wood, crossing the box one at each end, 2 inches below the surface. The upper and lower laths should be fixed one-eighth of an inch within the box, and the four remaining so arranged that there will be five interstices 14 inch in width—three for the Roses, and two merely to reduce the weight. There will be a space of 1½ inch between the laths and the upper edge of the box, to be filled as follows: Cover the laths with sheets of brown paper, two deep, and cut to fit the box, and upon these place the best moss you can obtain. The Roses are placed in tubes of zinc 4½ inches in length, 2 inches wide at the top, gradually tapering until they become 1 inch in width at the centre, the tops being moveable. This top is taken off, and the stalk of the flower being brought through until the Rose is held securely, it is replaced upon the tubes, previously filled with pure rain water." A stand for twenty-four blooms of Dahlias should be 48 inches in length by 18 inches in width from front to back. It should be raised at the back 7 inches, and 3½ inches in front. The holes should form three lines of eight each, and should be 6 inches from centre to centre, and 3 inches from the outside. The metal tube for the water may be 1 inch in diameter, and should fit into the holes of the board; the wooden tube to receive the bloom, and fitting into the metal tube, should rise 1½ inch above the board. The colour of the board should be a lively bright green. The dimensions of a stand for twelve blooms of Dahlias can be easily deduced from the foregoing. Such a box as that just described would be suitable for Roses if shown in single trusses; for single blooms of Roses the dimensions would be almost too large, while for bunches of three trusses it would scarcely afford sufficient space. For Roses the tubes may be fastened to the bottom of the box, not using a board as in the case of Dahlias, and the spaces filled up with fresh green moss. The most suitable colour for a box for Roses is dark green. You may use several boxes in showing a number of trusses or blooms. Chapin's cases are excellent, especially where flowers have to be sent to a distance.

CLIMBING ROSES FOR HIGH WALLS (E. M. E. A.).—Those mentioned are not all of them suitable. Retain *Marchal Niel*, *Lamarque*, *Climbing Devonensis*, a shy bloomer here, but a wonderful grower, and *Gloire de Dijon*. Add *Solfaterre*, yellow; *Triomphe de Rennes*, yellow; *Mdlle. Aristide*, pale yellow; *Céline Forestier*, yellow; *La Riche*, flesh white; *Académie*, white; *Ophiré*, orange and copper; and *Jaune Desprez*, red, buff, and sulphur. These will require some room to spread, as they are vigorous growers. Those marked with an asterisk will require much room overhead and on either side. They require but little cutting. Thin rootless wood, and merely top the shoots, whether extensions or fore-shoots, to the first good eye in sound wood. I did not cut my trees of *Céline Forestier* this year, and I never saw a more magnificent bloom. The yellow Tea-scented *Noisettes*, are, in my opinion, the most satisfactory Roses of the Rose kingdom. My trees of *Triomphe de Rennes* are at this time a wonderful sight. It is about the most satisfactory of all the yellow Roses.—W. F. RADCLIFFE.

PRUNING ROSES (Agnès).—As it is very difficult for a tailor to make a suit of clothes to fit everybody, so from different circumstances it is difficult to lay down any stiff rules of pruning. As a general rule cut out all weak and useless shoots, and such as awkwardly cross the other branches. Cut weak growers hard, and leave a liberal quantity of wood and of greater length on strong growers. If you find that the shoots which you call water-shoots bloom well from the sides, you should not cut them away. Apparently immature wood on a Manetti-stocked Rose will bloom abundantly if you cut the top of the shoot off, and cause it to break from the sides of the shoots. Soft shoots from the Briar will not always do this. If you find that cutting your Manetti Roses to 6 inches answers best, it is, of course, wise to do so. If the water-shoots on your standards are necessary to form the head let them stay, and cut them next spring, or shorten them after blooming is over.—W. F. RADCLIFFE.

PANSIES FOR BLOOMING IN SUMMER (Flora).—For spring you will need to have now good plants, fit for turning out where they are to flower when the bedding plants are removed. The beds should be well dug, and a liberal quantity of leaf soil and old rotting manure dug in, mixing it well with the soil. You must not expect the plants to continue blooming from spring until autumn. For summer flowering the cuttings ought to be put in now in a warm, sheltered situation, and be planted in spring in their summer quarters; and to make them bloom finely until autumn, it will be necessary to give liberal supplies of water in dry weather, and to mulch the beds about half an inch deep with short manure, which will be hidden by the foliage. Pansies are at the best very precarious bedding plants. They cannot stand the drought and heat of summer.

WINTERING GERANIUMS (Idem).—You would best succeed in wintering them in pots in the rooms, taking up the plants before frost, and placing them in light moderately dry soil. You could then pick off the old leaves as they become yellow, and cut away the shoots that damp off. They would not require much water, if any, between the time of potting and March, though a little might be given in mild weather to keep the shoots from shrivelling. You must keep frost from the plants; if you cannot, then the cellar would be the best place, removing all but the very small leaves, and storing the plants in dry sand. Only the roots should be covered. Examine the plants occasionally, and remove any damped leaves or shoots. There is little hope of your getting the cuttings taken from the plants to strike in a room, but you can, nevertheless, try it. Put them in light sandy soil.

LILY OF THE VALLEY SEED SOWING (F. C. H.).—By sowing the seed you will obtain plants, and may be fortunate in having something new. Keep the seeds in dry sand in a cool place, and sow them next March in

light sandy soil in a partially-shaded border, and cover with a depth of light soil about equal in thickness to the diameter of the seeds. Water in dry weather. About the third year they will flower.

CLIMBERS FOR A LOW WALL IN FRONT OF A LODGE (W. Armstrong).—We think you could not do better than plant *Cotoneaster* at the base of the wall, and it will cover it very closely like a carpet. *C. microphylla* would suit you best. It will need training, so as to cover every part of the wall regularly and quickly. For the lodge front, if the sun shine on it, we advise *Pyraeantha*, but if not, we should have *Ivy*. The Irish *Ivy* is good, and so is *Raxger's*, with fine h-b-l leaves. The *Yews* will bear any amount of cutting. It is best to cut them in spring before they begin to grow, and you need not be afraid of using even the saw. They will make fine shoots before autumn. We think the end of March or early in April the best time for heading them back.

PEACHES FOR WALLS AND TRAINING (J. M.).—There is very little room for selection when three kinds only are required, and we presume you do not want them to come in together, therefore we advise *Early York*, *Grosse Mignonne*, and *Barrington*. Three others equally good are *Noblesse*, *Royal George*, and *Violette Hative*. Fan training is the most suitable for out-door culture in England, as the trees vertically trained have the shoots much less vigorous at the base than at the top; indeed the lower branches not unfrequently die off altogether, and the trees are little better than standards.

BEEF FOR SPRING GARDENING (G. H.).—For this purpose it should be planted now where it is to remain, and so that the root will be covered, otherwise it is sometimes injured by frost. The old leaves ought to be left until spring, for they protect the plant, but in March remove them. It will be in good condition until the flower-stalks begin to rise, and after that we think it more suitable for the flower garden than at any other time.

DISTINGUISHING *SILENE PENDULA* FROM *S. PENDULA ALBA* (Idem).—The red sort has a much darker stalk than the white, whilst the leaves of the plant are of a deeper green. The latter variety is altogether lighter in appearance.

SHRUBS FOR THE FRONT OF A COTTAGE (A Cottage).—We think you will not find that you can have shrubs of the height you require without considerable cutting. Hollies would be most suitable, and we would have alternately pyramids and bushes, with opposite plants to match. We should have the plants 15 feet apart, putting in the first at 7½ feet from the cottage, and the last at the same distance from the road. If you should require six trees on each side, and commencing next the cottage, we would have *Gold-leaved (bush)*, *Hodgins's (pyramid)*, *Silver-leaved (bush)*, *masaderensis (pyramid)*, *Gold-leaved (bush)*, and *Hodgins's (pyramid)*, having the other side to correspond. Their distance from the walk should be half the distance they are apart, and they should be planted on grass. The earlier they are planted the better. You can cut them to any form, and have them of any height. They are best cut in spring, just before they begin to grow. The proper time to plant wall fruit trees is in November as soon as the leaves have fallen. With regard to your other question, you will find an article on the subject in a previous page.

GARDENIA CITRIFLORA SICKLY (Saccobium).—The cause of the plants looking sickly is probably want of heat, and the soil may have become sour from the plants having too much pot-room or defective drainage. We advise you to make the drainage good, and place the plants in a light, airy position in the stove, giving no more water than enough to keep the leaves from flagging. In February give them an increase of heat with bottom heat, if possible, and we have no doubt they will begin growing freely. Pot in March, removing from the roots all the soil that comes away freely, but be careful of them, and do not place them in pots larger than will hold the roots comfortably. They need a moist atmosphere and copious supplies of water.

HYDRANGEA NOT FLOWERING (Idem).—The plant could not be expected to flower this summer, as you cut it down last spring, and in so doing removed the flowering portion, for the wood of this year gives flowers the next.

ANECTOCYLUS DAWSONIANUS SICKLY (S.).—The best treatment you can adopt is to remove the plants at once and place them in fresh soil. Use a compost of equal parts of fibrous brown peat, sphagnum chopped up, and charcoal for the bottom of the pan or pot. Let the pot be efficiently drained, press the soil firm, and then surface with equal proportions of peat, charcoal, and silver sand. Keep the compost regularly moist, avoiding wetting the foliage, and take off the bell-glass every morning, wipe it dry, and replace it. It is desirable that the bell-glass should have a hole in the top; if not, tilt it a little on one side for a few hours every day.

TUSSELAGO FARFARA VARIEGATA, ALTERNANTHERA LINDENI, AND IRESINE AMABILIS PROPAGATION (O. W. M.).—The Tusseilago is increased by division of the roots in spring, dividing them into as many portions as there are growing parts, with some stem and roots to each. It is quite hardy, and likes strong, deep loam. The *Alternanthera* is increased by cuttings, which strike as freely as *Verbenas* in sand in a hotbed. The best plan is to strike cuttings now, wintering them in a warm greenhouse or cool stove. They will produce plenty of cuttings in February or March, and these, if forwarded in a hotbed, make good plants. *Iresine* is propagated in the same way, cuttings rooting very freely in a hotbed. *Alternanthera magnifica* has fine reddish bronze leaves, and is, like all the *Alternantheras*, useful for bedding out. It is raised like *Verbenas*, only it requires to be wintered in a warm house. You may increase them to a considerable extent by keeping them in heat.

EVERGREENS FOR TUBS (F. R. G.).—All things considered, we advise *Portugal Laurel*, *Laurustinus*, and *Hollies*, with *Sweet Bays* if the situation be mild. Handsome flowering evergreens will not succeed in tubs. We would have matched plants, two of each, and pyramid *Portugal Laurels*, *Gold or Silver-variegated Hollies*, and *Laurustinus*. They stand cutting well, and when in good foliage are very fine. You may select plants at most of the leading nurseries. We do not recommend dealers. Good plants of *Yucca recurva* are fine for tubs. They have a very distinct appearance.

APHIS ON BROCCOLI AND WINTER GREENS (J. B. S.).—The cabbage-plant louse (*Aphis brassicæ*) is making sad havoc in many places in the north, whole fields of Turnips being cleared off by them. We have it, and have tried lime, but without effect, the plague only comes on by

degrees. We do not think soot would be of any use. If we could obtain it we should use the ammoniacal liquid from the gas-works, sprinkling the plants all over, so as to wet every part; and if it were possible we would supplement with a drenching of liquid manure between the rows. With us the parents fly about in clouds, settling on the leaves they deposit their eggs, and the young soon hatch. We have had more insects this year than we ever remember.

PLANTS FOR CONSERVATORY (J. R.).—We should advise you to commence with a few of the commonest plants, which are, nevertheless, good:—*Acacia armata*, *A. oleifolia elegans*, *A. pulchella*, *A. magnifica*, *Chamaerops excelsa*, *Conozoma cordatum splendens*, *Citrus Aurantium* (Orange), *Cytisus racemosus*, *Dracena australis*, *Habrothamnus elegans*, *Hydrangea japonica* and var. *variegata*, *Kalosanthes coccinea superba*, *Myrtus communis* (Myrtle), *Nerium rubrum plenum*, *Polygala Dalmaisiana*, *Rhododendron javanicum*, *Princess Royal*, *Princess Alexandra*, *Jasminiflorum*, and *Vallota purpurea*. *Camellias* you may add advantageously as you feel disposed, also *Azaleas*, with *Primulas*, *Cyclamens*, *Cinerarias*, and *Calceolarias* you may have a nice show. We cannot account for the *Balsams* and *Primulas* failing. Much depends on the treatment.

HEATHS (Jay Cec).—Do not apply the liquid manure. If potted in fitting soil they will only require a regular supply of water.

SEEDLING HOLLYHOCK (Westmoreland).—Quite smashed. It should have been sent boxed in damp moss.

SEEDLING POTATO (W. Thomson).—The samples you sent us of the seedling you have named "Favourite," were mealy and well flavoured when boiled. The tubers were middle-sized, flattish-oval, eyes few and not deeply sunk, skin rough. They seem to be akin to the Forty-fold.

RAISING SUBTROPICAL PLANTS (A Subscriber).—Canas will succeed by both the modes you name—first, by securing the roots when they are taken up, and storing in sand in a collar, potting in March, and forwarding in a hothed; second, by sowing in a hothed in February, forwarding, and hardening well off before planting out. *Wignandia caracasana* is propagated by cuttings of the roots in a hothed in spring, and best by cuttings of the shoots. *Ferdinandia eminens* is also propagated from cuttings either at the end of summer or in spring. *Polymnia grandis* is increased by cuttings of the old plants placed in heat in spring, the cuttings being inserted in a brisk bottom heat. *Nicotiana*, or Tobacco, is raised from seed sown in light soil in a hothed in March, pricking off when large enough, growing in heat, and hardening off before planting out. The *Alternantheras* are propagated from cuttings put in new, or better in spring, in light soil, and placed in a hothed. All succeed in a light fibrous loam, with one-third leaf soil or well-rotted manure.

YOUNG FOREST TREES OVERGROWN WITH GRASS (Lieut. Col. H.).—If your communication had reached us two months earlier, we should have had no hesitation in advising you to clear the ground of all herbage; but now, as autumn is set in, we are afraid there is some truth in the popular notion of which you speak—that long, rank grass and other weeds afford shelter to the young trees; this they unquestionably do, but there are very few cases indeed in which the trees could do better without such shelter, if it were removed early in the summer, so that the young trees would become well hardened by gradual exposure to the autumn colds, so as to withstand the storms of winter. In your case we should be inclined to wait till spring, and then clear everything away, but not carrying anything off the ground. Assuming the trees to be 2 feet high and 4 feet apart, we would remove the long grass and weeds to the distance of a foot or more all round the collar of each plant, with a hoe or something of that kind, but not penetrating the ground so deeply as to injure the tree roots. We would leave the rubbish in heaps between as to injure the tree roots. We would leave the rubbish in heaps between as to injure the tree roots. We would leave the rubbish in heaps between as to injure the tree roots. In summer a few hoings in suitable weather will preserve neatness. Not knowing the character of the soil and other particulars of your case we can give no opinion of the soil and other particulars, but if it is damp and boggy, or even consists of dry peaty soil, Beech trees, which you speak of as forming part of the plantation, are the most insupportable of any, as that tree likes a chalky or dry stony soil. Where large breadths of moorland are planted without undergoing any preparation, merely planting on the thick grassy or mossy sward, it is good practice to clear the rubbish away with a hoe or something of that kind, once at least early in summer, leaving the later growth to form that natural shelter for winter, which, after all, is not without its advantages.

APPLES GRAFTED ON FRENCH PARADISE STOCKS (L. & W.).—The French Paradise stocks are employed by Messrs. Rivers, Sawbridgeworth, but not recommended, because they require a warm, generous soil and climate. They form very dwarf trees, but not of greater fertility than the best dwarf English Paradise—the Nonesuch, of which trees were exhibited at South Kensington on Wednesday last. These trees were 18 inches or so in height, two and three years old, and full of fruit. Some Apple trees on the French Paradise at Sawbridgeworth are from ten to twelve years old, and not more than 18 inches high. They are full of fruit. They have been lifted twice or thrice. Some of the trees are affected with canker, the great fault of this stock. On the Nonesuch Paradise, trees of the same age, and under the same treatment, are about 2 feet in height. They are equally loaded with fruit, and free from canker.

TREES FOR A SLOPING LAWN (Leadbeater).—We presume you would require principally evergreens with a few deciduous trees. Of trees proper, we would have Purple Beech, both the common Horse Chestnut and the pink, the Weeping Birch, the Elm, the Lime, the Fern-leaved Beech, the scarlet Oak, the variegated Sycamore, and the scarlet Maple. These we should place as near the outside as practicable. Then you will need the Mountain Ash, Stag's-horn Sumach, double pink, scarlet, and white Thorns, with the double Cherry, and Siberian Crab. Of evergreens we should have *Picea Nordmanniana*, *P. nobilis grandis*, *P. Pissapo*; *Cupressus Lawsoniana*, *Pinus Combra*, *P. excelsa*, *P. austriaca*, *Thuja Lobbi*, *Thujopsis borealis*, the American and Chinese *Ahor-Vite*, *Cedrus Deodara*, and *C. Libani*, with *Hollies*—Gold and Silver-variegated, *Hodgkins's*, and *altacerensis*—*Portugal Laurels*, Irish and common *Yew*. These well arranged would have a fine effect.

GARIBALDI STRAWBERRY (W. Thomson).—It is evident that you had Vicomtesse Horticulteur de Thury sent you. As for verifying the merits of new varieties, the editor who undertakes such a task would be a very unwise man.

POTATO (H. S. Cornuby).—We cannot profess to name Potatoes from a single example. Most probably it is a mere local variety.

APPLE JACQUES LEBEL (R. D.).—It is described in Downing's "Fruits and Fruit Trees of America" as being of much beauty, but of ordinary quality. "Fruit large, roundish oblate, lemon yellow, shaded with red in the sun, many grey dots. Stalk large. Cavity deep. Calyx half closed. Flesh white, tender, mild, subacid."

NAMES OF FRUITS (Richard Taylor).—No. 1, which you bought for Glou Morgean, is *Beurre de Capiaumont*; 2, *No plus Meuris*, we believe is simply the stock; 3, *Easter Beurre*, we believe is *Duc de Nemours*; 5, *Keswick Godlin*, is correct. (*H. L.*)—We believe the Crab is the *Yellow Siberian*; 2, the pale Apple is most likely a local kind; it resembles *Broad-eyed Pippin*; 3 is *Braddick's Nonpareil*. *Munche's Pippin* is not a synonym of *Margil*. (*W. W.*)—*Plum*: 11, *Coe's Golden Drop*. *Apples*: 1, *Court of Wick*; 2, *Winter Gold Pearmain*; 7, *Constanza*; 10, *Hawthornden*. *Pears*: 5, *Beurre de Capiaumont*; 8, *Easter Beurre*; 9, *Vicar of Winkfield*; 12, *Louise Bonne de Jersey*. (*Rev. H. H. Dombtrain*).—*Pears*: 1, *Comte de Lamy*; 2, *Beurre de Capiaumont*; 3, *Beurre diel*; 4, *Marie Louise*; 5, *Forelle*; 6, *Napoleon*. *Apples*: 2, *Wesh Pippin*; 3 and 9, *London Pippin*; 4, *Alfriston*; 5, *Royal Russet*; 8, *French Godlin*; 10, *Probably French Crab*; 11, *Ribston Pippin*; 12, *Hawthornden*; 13, *Like Biswingwood Russet*; 15, *King of the Pippins*; 16, *Aibans*; 17, *Yellow Inglesrie*. (*T. G. Bedford*).—*Empereur Alexander*. (*T. J. Herbs*).—*Apples*: 1 and 1, *Fearn's Pippin*; 2, *Hollandbury*; 3, *King of the Pippins*; 15, *Dumelow's Seedling*; 19, *Alfriston*; 18, *Rymer*; 20, *Blenheim Pippin*. *Pears*: 2, 4, *Winter Nohis*; 1, *Marie Louise*. *Peaches* cannot be named without the flowers and leaves. These were much confused, and several without numbers. Do not stick numbers on with pins. (*Without Name*).—*Apple*: *Longville's Kernel*; 14, *Court of Wick*. *Pears*: 20, *Althorp Crassane*; 62, *Hacon's* incomparable; 50, rotten. (*J. C. Bromley*).—The Bean is called the *Asparagus Runner*. The Apple we do not recognise. (*G. Birdhill*).—The Pear is *Flemish Beauty*.

NAMES OF PLANTS (A Subscriber, G. A. B.).—We cannot undertake to name florists' flowers. There are hundreds of *Geraniums*, and the only mode we can suggest of ascertaining the name is to compare it with the varieties in some good collection in your own neighbourhood. (*J. H. B.*)—Your *Fungus* is the *Fairy-ring Champignon* (*Marasmius oreades*), one of the best of edible Fungi.

POULTRY, BEE, AND PIGEON CHRONICLE.

LIABILITY OF SECRETARIES FOR THEIR MISTAKES.

I ENTERED two pens of birds for the Keighley Show, but the Secretary, Mr. R. Fawcett, never sent me labels for the hampers, consequently I was prevented showing my birds. I wrote for my entry money to be returned, but received no answer. I twice repeated my application, and threatened taking proceedings against him if the money were not returned in due course, but no notice was still taken, consequently I entered him in the County Court, where he was compelled to pay the money, together with the court expenses. I hope the above will be a lesson to others placed in a like position to myself.—JAS. GLESSALL, *Old Hall, Mithorpe*.

BIRMINGHAM POULTRY SHOW, 1870.

I FANCY that most exhibitors will agree with the remarks of Mr. L. Wright about the schedule for the present year, especially as regards the measures necessary to lessen the number of entries. It is a great mistake, I believe, to continue the present form of subscription and entries, with six admission tickets. It is well known that there is always a large sale at Birmingham; it is known, too, that with the enormous number of entries pens have received notice from the Judges, whilst their merits perhaps scarcely deserved it. Many exhibitors doubtless enter pens on this speculation, as they have four pens to fill up; and so, if we examine the entry list, fours, or some multiple of the mystic number, are the rule.

I have in bygone years in your columns complained of the illiberality of the Birmingham Committee to the exhibitors of "Any other variety." I consider that at Birmingham there should be at least two first, second, third, and fourth prizes, say £14. This is not too much. Considering that to this class we owe the introduction of the *Brahmas*, French fowls, and other now thoroughly established favourites, and considering that at many comparatively insignificant shows an equal amount is offered, I trust another year will mark a great addition to these prizes. Is it too late for the Committee to advertise that there will be two sets of prizes at the next show?

I have often thought that *Guinea Fowl* deserve a class to themselves at Birmingham. Surely *Japanese* (*Bantams*, I presume), have a refuge in Class 80; I cannot but think that *Silkie*s ought to go there also.

A few words about the *Malay* prizes. Birmingham does still retain classes for this breed, and during the past year and this the Committee have been assisted by exhibitors. I am bound to say that this year, in forwarding the amount collected, I expressed the hope that the Committee would apportion the

amount between first and second prizes more equally, and had hoped this would have been done. I am certain that last year entries were lost on this account. I am disposed to think it will lessen my entries now. It seems now-a-days legitimate to hit the poor Malays hard; but my good friend, Mr. L. Wright, would hardly have penned his few remarks about their entries last year if he had studied the catalogue of 1869. For instance, there are some classes of Malays that paid the Committee far better than did some of the classes of other breeds! This is a monstrous thing for me to state; perfectly untrue some may probably think the statement, but let me come to chapter and verse. Class 31, Malay hens over one year, had seven entries; or let me make the following table as a comparison:—

Class and Breed.	No. of Entries.	Amount at 3s. per pen.	Prizes offered.
		£ s.	£ s.
Class 17.—Cochin (White).—Cocks over one year.	8	1 4	5 0
Class 27.—Brahma (Light).—Hens over one year.	9	1 7	5 0
Class 37.—La Flèche.—Cocks	4	0 12	4 0
Class 38.—Ditto.—Hens	5	0 15	4 0
Class 47.—Hamburgs (Silver-pencilled).—Cocks	9	1 7	5 10
Class 70.—Game (Duckwing).—Hens	7	1 1	4 0
Class 74.—Game (White and Pile) Cocks		1 4	5 0
Class 31.—Malay.—Hens over one year	7	1 1	3 10*

I may mention that there are one or two other classes that only equal this Malay class—for instance, Class 19, White Cochin hens. I have purposely omitted the Polish. Alas! like the Malay, they are no longer fashionable, and I have preferred taking the fashionable varieties.

I will agree that the breed has deteriorated. Is it wonderful when of late so little encouragement has been offered to it?—Y. B. A. Z.

MALAYS—REVISION OF CLASSES.

I was much pleased with the remarks made by Mr. Wright in your last week's number about the Birmingham Show of 1870. Touching Malays, true it is that a few amateurs have again this year subscribed each a guinea rather than have the class expunged from the prize list; but surely these amateurs must feel disappointed at the manner in which the prizes have been distributed in the four classes—viz., £3 the first prize and 10s. the second prize. Without further comment, although there is no accounting for taste, as an exhibitor I infinitely prefer the first prize. Judging from what I have seen and heard, I think that Malays this year will be better represented than ever, and that, owing to recent importations, Mr. Wright will have no reason to think that the breed is deteriorating. Several amateurs have lately started Malays, and I trust that they will enter them for competition at Birmingham, and let the committees of other shows see that henceforth they will be deserving of a class to themselves, and not be obliged to take refuge in the "Variety class" to be beaten, as has often been the case, by Silkies.

It would indeed be a great boon if many committees would revise their poultry prize lists, and not issue the same, as is usually the case, year after year. Why should there not be a class at every principal show for Black Hamburgs, one for Polish of any variety, and one for French fowls of any variety? At the last three shows that I have attended Black Hamburgs and Silver Polish have been first and second in the "Variety class," and many really good pens of French fowls, Malays, Gold-faced Bantams, &c., have been obliged to be content with high commendations. I am satisfied that if these three classes I have mentioned were to be found in the prize lists for 1871 they would not only be well filled, and the show rendered far more attractive, but greater encouragement would be given to the breeders of these excellent varieties.—A. G. BROOKE, Ruyton XI.-Towns, Salop.

NEW POULTRY MARKET.—It is satisfactory to learn that a Poultry Market is in contemplation, the proposed site being a piece of vacant ground adjoining the Metropolitan Meat Market. This would be a valuable addition to our already existing organisation for the supply of animal food. Next, we should like to see good and cheap vegetable markets, in which the poorer districts of London are sadly deficient. Perhaps the formation of one for poultry will cause more attention to be

paid to their fattening, from neglect of which we lose an immense amount of good food; and, as a commercial question, it would amply repay any country gentleman to try the experiment, as recently detailed in this Journal. Some years ago a Mr. Brooke attended before the Food Committee of the Society of Arts, and gave some very valuable information on the subject, which he offered to make known to the country at large, by going down to various towns on their market days, and instructing the small farmers and cottagers. But no action was taken upon it, as ought to have been the case, and so a valuable opportunity was allowed to slip away.—(Food Journal.)

[It is stated by the City authorities that the piece of ground referred to above affords double the area of the spacious Meat Market, and it is even more conveniently situated for those who are likely to be purchasers of poultry, being in the immediate neighbourhood of the Farringdon Street Station of the Metropolitan Railway.—Eds.]

RULE AGAINST TRIMMING.

CAN you, or any of your correspondents, inform me how it is that the Committee of the Birmingham Poultry Show have not a rule against trimming? I was quite surprised and disappointed, when I looked over the rules for this year, to find that they should have omitted such an important one, more especially so, as the Birmingham Show is considered the leading one of the day, and one which should set an example to the smaller exhibitions. Honest exhibitors do not like to trim their birds, neither do they like to be beaten with birds with pickled feathers. I sincerely hope that the Manchester and other leading shows will adopt a rule against such fraudulent practices, or else honest exhibitors will give up exhibiting.—A DISGUSTED EXHIBITOR.

SELLING EGGS BY WEIGHT.

WHEN eggs were worth from 6 to 12 cents per dozen, it was a matter of no great importance whether they were large or small, but now as they range from 20 to 40 cents per dozen, there is an item worth looking after in selection. There is nearly a difference of half in the amount of meat to be found in different lots of eggs on the market, and justice can never be done to the purchaser until they are sold by weight. Eggs weigh usually 1 1/2 lb. per dozen, and at 40 cents per dozen are expensive meat. When sold for breeding purposes, the present custom of counting may be the best. There would be an advantage to the producer resulting from a change as above suggested as well as to the buyer, for then every keeper of poultry would seek such breeds as would produce the greatest number of pounds in eggs, while now a hen which is prolific is profitable, let her eggs be as small as those of the Partridge; the object being to get number, not size or quality.—(Ohio Farmer.)

PRIZES FOR ANTWERP PIGEONS.

I HAVE read in your pages various letters advising persons about to purchase birds for forming a flock to have the Antwerp on account of its usefulness, quick breeding, and numerous other good properties. I quite agree with the writers, having kept birds of that breed for some time; still there is one great drawback to persons who keep them as a hobby, and like to show them now and then in order to know the merits of their birds—it is that at few shows are prizes given for this class of Pigeons. Now, I think this is a mistake, and I imagine if the committees could only read the letters to which I have referred, they would soon offer prizes, if not cups, for this class.—H. P. RYLAND.

ECCLESFIELD (SHEFFIELD) POULTRY AND PIGEON SHOW.

THIS Show was held on the 29th ult., and was one of the sections of the Agricultural Exhibition, and although there was but one prize offered in each class, yet the muster in point of both quantity and quality was of a respectable character.

The adult fowls were generally good, though most were in deep moult. The *Cochins*, *Spanish*, and *Polands* were of high quality, and shown in the very best of bloom and condition. The first-prize *Dorking* chickens were dark Greys, of enormous frame and good shape, and there were also several grand cockerels, with bad pullets. The Spanish chickens were also of nice quality, but the

* In this case amateurs assisted the Committee to offer the prizes.

Game only moderate as a class, though several single birds were very fine. The *Hamburgh* chickens in the winning pens were all correct specimens, and the winners in *Game Bantams* also good birds. The single *Game cockerel* was a capital bird in form and style, but a little flecked in feather. The *Geese* were large, but did not match in colour. There was but one class for *Ducks*, and *Aylesburys* won the prizes. There were large and excellent pens of birds, and many more prizes might easily have been distributed in the class. In *Pigeons* there were some good birds, notably the *Carriers*, which were Black. The *Almond Tumblers* were good and the *Blue Pointers* in the first-prize pen were of great length of limb and feather, closely pressed by a pair of capital *Red-pied*. In the "Variety class," *Black Swallows* were first, and *English Owls* and *Ice Pigeons* highly commended.

DORKINGS.—1, W. HARVEY, Sheffield. c, T. W. Overman, Sheffield Lane, Paddock. *Chickens*.—1, W. HARVEY, he, F. Crawshaw, Lonsley. c, F. Crawshaw; J. Swift, Deardlands. SPANISH.—1, Burch & Boulter, Sheffield. he, E. Brown, St. Philip's Road. *Chickens*.—1, E. Brown, he, Burch & Boulter. COCHIN-CHINA.—1, W. HARVEY, c, J. Boler, Hilltop. *Chickens*.—1, Burch and Boulter. he, J. Tomlinson, Sheffield. GAME.—1, F. Moody, Treoton. c, J. Denton. *Cockerel*.—1, F. Moody. *Chickens*.—1, W. Holden, he, W. Holden; M. E. Chambers, Chapeltown. *HAMBURGHS*.—*Golden-spangled*.—1, W. HARVEY, he, Burch & Boulter. *Chickens*.—1, Burch & Boulter. *Silver-spangled*.—1, W. HARVEY, he, F. Turner, Sheffield. *Chickens*.—1, W. HARVEY, he, F. Turner. *Golden-pencilled*.—1, W. HARVEY, he, Burch & Boulter. *Chickens*.—1, W. HARVEY, he, Burch & Boulter. *Silver-pencilled*.—1, W. HARVEY, he, W. Stead, Owlerton. *Chickens*.—1, W. HARVEY, he, W. Stead. BANTAMS.—*Game*.—1, J. Uylett, Pitonoor. he, J. Boler. E. Moody; W. Topham, Sheffield. *Any Variety*.—1, J. Tomlinson. c, W. Topham. *ANY VARIETY*.—1, W. HARVEY, GEESSE.—1, G. JACKSON, Munsborough. he, W. Shaw, Drakes. J. S. Shillite, Sheffield. he, J. K. Straw, Shiregreen (Ronen); E. Temple (Aylesbury); F. Crawshaw. TURKEYS.—1, Mrs. Booth, Brightholme. he, Mrs. Booth; G. JACKSON. c, G. JACKSON.

PIGEONS.

CARRIERS.—1, W. HARVEY, he, E. Brown, Sheffield. **TUMBLERS**.—1, W. HARVEY, he, E. Brown; H. Brown, Walkley. c, J. B. Mabson, Ecclesfield; J. Rider, Middleton. **FANTAILS**.—1, W. HARVEY, he, E. Brown; H. Brown, he, R. Cauwood, Ecclesfield. **JACOBIANS**.—1, W. HARVEY, CROPPERS or PORTERS.—1, W. HARVEY, he, H. Brown. **ANY OTHER VARIETY**.—1, W. HARVEY, he, G. Milner, Grimsthorpe; E. Temple (White Trumpeters); W. HARVEY.

The Judge was Mr. E. Hatton, Padsey, Leeds.

LITTLEBOROUGH POULTRY SHOW.

The following awards were made at this Show, held on Sept. 24th:—

GAME.—1 and 2 C. W. Brierley, Middleton. *Cock*.—1, E. Aykroyd. 2 and he, C. W. Brierley. *Hen*.—1 and 2 C. W. Brierley. he, T. J. Sunderland, Halifax. **BRAHMS**.—1, R. Hutchinson, Littleborough. 2, W. Trevor, Rochdale. he, J. Yates, King's Heath, Birmingham; J. T. Travis, Rochdale. **COCHINS**.—1 and 2, J. Greenwood, he, C. Whitehead. **BANTAMS**.—*Game*.—1 and 2, J. W. Morris, he, F. Steel, Halifax. *Any other variety*.—1, J. W. Morris. 2, J. H. Pickles, Birkdale, Southport. he, S. & R. Ashton, Mottram. T. Dixon. **DORKINGS**.—1, W. H. King, Rochdale. 2, H. Pickles, jun. he, J. Stott, Healey. **SPANISH**.—1 and 2, C. W. Brierley. **HAMBURGHS**.—*Golden-pencilled*.—1 and 2, T. Wrigley, jun., Middleton. he, H. Pickles, jun. *Golden-spangled*.—1 and 2, T. Wrigley, jun., Middleton. 2, H. Pickles, jun. *Silver-pencilled*.—1 and 2, H. Pickles, jun. *Silver-spangled*.—1 and 2, H. Pickles, jun. he, J. Cockerott, Kedgeley. *Black*.—1 and he, E. Brierley, Heewood. 2, C. W. Brierley. **ANY OTHER VARIETY**.—1, P. Unsworth. 2, H. Pickles, jun. c, W. Unsworth; H. Pickles, jun.; B. Hurst, Rochdale. **SELLING CLASS**.—1, W. Trevor. 2, C. W. Brierley, he, S. Crossley, Rochdale; G. Taylor, Huddersfield; H. Pickles, jun.; J. W. Brierley.

LOCAL CLASSES.

GEESSE.—1, J. Shepherd, Smallbridge. he, R. Hurst; F. Lord, Littleborough. **DUCKS**.—*Aylesbury*.—1, J. Buckley, Littleborough. 2, M. A. Crossley, Littleborough. *Rouen*.—1, E. Hurst. 2, R. Hutchinson. he, A. Consterdine; J. Walton; E. Lord. *Any other variety*.—A. Consterdine. 2, W. Stewart, Rochdale. **TURKEYS**.—1, G. Taylor, Littleborough.

PIGEONS.

PORTERS.—1, J. Hawley, Bingley. 2, H. Yardley, Birmingham. **CARRIERS**.—1, J. B. Pinder. 2, G. Taylor, he, H. Yardley, he, A. Consterdine. **TUMBLERS**.—*Almond*.—1, J. Fielding, jun., Rochdale. 2, H. Yardley. *Any variety*.—1 and 2, J. Fielding. he, F. Moore, Burnley. he, H. Yardley. **DRAGOONS**.—1, J. Wild. 2, J. Stanley, Blackburn. *he, H. Harreaves, Burnley. he, F. Graham; J. Watts. c, P. Unsworth. FANTAILS*.—1, J. F. Lovelandside, Newark-on-Trent. 2, H. Yardley. c, F. Graham; J. Hawley. **BABBS**.—1 and 2, J. Fielding, jun. he, A. Dove, York. **JACOBIANS**.—1, J. B. Pinder. 2, J. Hawley. **ANSWERS**.—1, E. Lee, Colne. 2, J. B. Pinder. he, S. T. Heap, Littleborough; J. Oldroyd, Wakefield; he, J. A. Colbison, Halifax; J. Oldroyd. **TERNTS**.—1, J. Fielding, jun. 2, J. B. Pinder. he, F. Moore; he, H. Yardley; A. Dove. **TRUMPETERS**.—1 and 2, J. Hawley. he, P. Unsworth. **OWLS**.—1 and 2, J. Fielding, jun. he, J. Stanley; A. Dove. **ANY OTHER VARIETY**.—1, J. Watts. 2, F. Graham.

JUNGES.—*Poultry*: Mr. R. Teebay, Preston. *Pigeons*: Mr. Kidpeth, Handforth.

OSWESTRY POULTRY SHOW.

This Meeting was held on September 29th, and being favoured by most lovely weather, there was an extraordinary attendance of visitors. The *Dark Brahmans* formed one of the most praiseworthy features of the whole Show; and in the face of a good competition the Hon. Miss Douglas Pennant took both prizes with birds shown not only in the most admirable condition, but such as have not as yet been brought before the public this season. They will in all probability add yet more triumphs to that lady's yard, as the prohibitory price of £20 each couple prevented their immediate appropriation. Many of the *Cochins* shown were capital chickens; Mr. Sidgwick took the chief prizes for these. *Hamburghs* were among the gems of the Show, and as they appear to be so little known in this district, the anxiety evinced by the public for a close inspection of these particular classes was extraordinary. The *French fowls* had separate classes, and both breeds were well and numerous shown. An amateur may attend many shows ere he meets with so excellent a class for *Any other variety* as there was at Oswestry: every pen obtained the favourable notice of the Judge. *Geese*, *Turkeys*, and *Ducks*, as is always the case at Oswestry, were remarkably good. Although here and there was to be seen an

unexceptionally good pen of *Game fowls*, there was not nearly such excellence in these breeds as at former shows.

GAME.—*Black or Brown-breasted Red*.—1, M. A. Forde, Maghull (Brown Reds). 2, J. Mason, St. John's, Worcester (Black-breasted). he, Rev. F. G. Bentley, Felton Grange (Black-breasted). *Duckwing Greys and Whites, or Piles*.—1, W. Dunning, Newport, Salop. 2, Barker & Charnock, Illingworth. he, J. Mason. c, Miss Saddler, Whitechurch. *Any colour*.—1, F. Parlett, Great Haddow (Coloured). 2, Rev. E. Bartrum, Great Berkhamstead (Coloured). he, E. Shaw, Oswestry (Coloured); T. Briden, Erby, Skipton (Coloured). c, E. Williams, Henlys, Berwick (Coloured). **COCHINS**.—*Brown or Partridge*.—1, C. Sidgwick, Ryddlesden Hall, Keighley. 2, no competition. *White or Buff*.—1, C. Sidgwick (Buff). 2, J. Dove, Moulton (Buff). he, A. Darby, Stanley Hall, Bridgnorth (Buff). c, T. H. Readman, Whitby (Buff); D. Thomas, Brecon (Buff). SPANISH.—1, J. Boulton, Bristol. 2, Mrs. Clews, Walsall. he, F. James, Peckham Rye; E. Brown, Sheffield. **BRAHMA POOTRAS**.—*Dark*.—1 and 2, Hon. Miss D. Pennant, Penrhyn Castle, Bangor. he, E. Leech, Rochdale. c, Rev. J. Evans, Crompton Rectory, Brecon. *Light*.—1, H. Dowsett, Pleshey, Essex. 2, T. Deane, Witley, London. **COCHIN-CHINA**.—*Brown or Partridge*.—1, W. Speakman, Dodington Park, Nantwich (Gold-pencilled). he, H. Pickles, jun., Erby. c, H. Pickles, jun.; T. H. Readman, Stoke-on-Trent (Gold-pencilled); J. Platt, Bolton (Silver-pencilled). *Silver or Gold-spangled*.—1, T. May. 2, H. Pickles, jun. he, Duke of Sutherland; Ashton & Booth, Broadbottom, Mottram (Silver-spangled). **CREVE-COEURS**.—1, J. J. Malden, Biggles, Walsall. c, E. Williams, W. W. Spring, Faversham; G. Bennett, Grove-Shipfall, Hotters. he, W. G. Unwin, Birmingham. E. Williams, ANY OTHER VARIETY.—1, Duke of Sutherland (Black Hamburghs); 2, H. Pickles, jun. (Silver Poland); he, C. Sidgwick (Black Hamburghs); Rev. A. G. Brooke, Ruyton XI-Town (Malays); W. Gamon, Chester (Polonds) (2). c, A. D. Payne, Luth Hill (Malays). **BANTAMS**.—*Game*.—1, F. Steel, Halifax. 2, J. Adams, jun., Walsall. c, J. Teggin Cross Foxes, Guboven (2). *Any other Variety*.—1, T. C. Harrison, Hull (Gold-laced Sebrights). 2, C. Drake, Stoke, Ipswich (Black Brahmans). he, Rev. A. Brooke (Maltese). c, E. Lodge, Erby, Cheshire (White); H. Yardley, Birmingham (Gold-laced Sebrights); T. C. Harrison (Silver-laced). **TURKEYS**.—*Polts*.—1, E. Leech. 2, E. Shaw. **GEESSE**.—*Goslings*.—1, E. Leech (Toulouse). 2, E. Leech. **DUCKS**.—*Aylesbury*.—1, E. Leech. 2, J. Dove. *Rouen*.—1, E. Leech. 2, F. Parlett. c, G. Cottle, Westleton. **SELLING CLASS** (Any breed).—1, E. Shaw (Cochins). 2, T. Foulkes, Oswestry (Black-breasted Game). he, H. Yardley; J. M. Foulkes, Llandyfaelog Rectory, Montgomery (Light Brahmans). c, E. Williams (Dorkings); Rev. J. J. Evans (Brahma Pootras). **GAME**.—*Black-headed*.—1, E. Pugh, Welshpool (Black-breasted Red). 2, S. White. **OSWESTRY** (Black-breasted Red). *Any Colour*.—*Bullets*.—1, S. White. 2, G. Cottle. he, Rev. P. G. Bentley, Felton Grange (2). c, E. Shaw. *Cock*.—1, S. White. 2, E. Pugh. **DORKING**.—*Chickens*.—1 and 2, E. Shaw.

The Judge was Mr. Edward Hewitt, of Sparkbrook, Birmingham.

DERBY POULTRY SHOW.

This Show was exceedingly well arranged, and the competition was exclusively confined to birds of the present year; notwithstanding, the prizes were, as a whole, very well contested. Some very good *Dorkings* were shown, but it should be borne in mind by competitors that however perfect in other respects birds may be, malformations of any kind are always inadmissible. A few of the pens of *Game* chickens were really good, but the majority of those shown were scarcely sufficiently matured for the show pen. The *Hamburghs* were the best ever yet seen at this Society's shows, and were excellent. The *Brahmas* were also worthy of very high approval, particularly the *Dark-feathered*. A large entry of cross-breeds, shown entirely on their merits as table fowls, caused considerable interest. The *Geese* were one of the most meritorious classes in the Show, and embraced Toulouse, White, and Saddle-backed. The special prizes for three pens of poultry of any variety, shown by one exhibitor, brought a competition of seven entries, and visitors seemed to regard this portion of the Derby Exhibition with unusual attention. *Pigeons* proved scarcely so good as we had hoped to find them. The promptitude, care, and attention of the Committee in the general management could not be surpassed, and the summer-like weather caused an immense influx of visitors.

DORKINGS.—*Coloured*.—1, A. F. Hort, Aldersley. 2, Countess of Chesterfield. he, G. J. Mitchell, Newark-on-Trent. c, Mrs. Arkwright, Sutton Scarsdale. *White*.—1, J. Faulkner, Bretby. 2, W. R. Dick, Ticknall. **GAME**.—*Dark-breasted*.—1, C. Minors, Sudbury. 2, G. J. Mitchell. c, J. Faulkner. *White or Pile*.—1 and he, W. Hollingworth, Dale Abbey. 2, C. Spencer, Thilston. **HAMBURGHS**.—*Gold-pencilled*.—1, H. Hineckley, Radbourne. 2, J. Bakewell. he, G. J. Mitchell. *Gold-spangled*.—1, J. Bakewell. 2, H. Hineckley. *Silver-pencilled*.—1 and 2, H. King, Melbourne. c, J. Bakewell. *Silver-spangled*.—1, C. Picketing, Kirk Landley. he, H. Hineckley. c, J. Bakewell; A. F. Hurt. **COCHIN-CHINA**.—1, J. E. Story. 2, G. A. Crewe, Etwell. **BRAHMS**.—*Light*.—1 and 2, A. O. Worthington, Burton-on-Trent. *Dark*.—1 and he, A. F. Hurt. 2, Rev. E. Alder. c, Rev. E. Alder; A. O. Worthington. **CROSS-BRED**.—1 and 2, A. O. Worthington. **DUCKS**.—*Rouen*.—1 and 2, A. O. Worthington. c, G. J. Mitchell. *Aylesbury*.—1, J. E. Story. 2, and c, G. A. Crewe. **GEESSE**.—1, F. Potter, Harbottle Moor. 2, J. Faulkner. c, J. Milnes, West Hamlyn; G. J. Mitchell; G. A. Crewe. **TURKEYS**.—1, G. J. Mitchell. 2, A. M. Mundy. **SPECIAL CLASS FOR BEST THREE PENS OF POULTRY**.—1, A. A. O. Worthington (Light Brahmans). 2, Mrs. Arkwright (Game). 3, G. A. Crewe (Partridge Cochins).

PIGEONS.

ROCK or DOVECOCK.—1, G. J. Mitchell. 2, J. Faulkner. **ANSWERS or BELGIANS**.—1 and 2, Mrs. Arkwright. c, J. Langley, Mickleover. **TUMBLERS**.—1, Mrs. Arkwright. 2, F. B. Wright. **FANTAILS**.—1, W. R. Dick. 2, J. Wood, Spendon. **ANY OTHER VARIETY**.—1, Capt. Fountain, Derby (Black Pointers). 2, W. R. Dick (Yellow Jacobins). c, Mrs. Arkwright (3) (Maapies).

The Judges were Mr. Edward Hewitt, of Birmingham, and Mr. Edward Lowe, of Comberford.

CANARY BUG.

HAVE any of your numerous readers in the Canary fancy ever tried the following simple remedy for the destruction of that dreadful pest, the Canary bug? Obtain pieces of elder wood, force out the pith, pierce several holes through the wood, so as to enable the little animals easily to find their way into the hollow, shake or blow through the perches into a basin of

hot water at cleansing time, and the result will be, if in accordance with my experience, very satisfactory.—J. M. S.

[That little gentleman, the Canary bug, is naturally of a retiring disposition, and will retreat into any crack, however small. If there be any crevice, even if almost imperceptible, it will soon be tenanted when the pests make their appearance. It is quite unnecessary to make traps for them. Any which might explore the hollow perch would form but a very small part of the regiments quartered in every available locality; and accommodation, however kindly intended, would not be by any means an effectual check upon them. I would feel disposed to cut off every retreat rather than to find furnished lodgings for them. Fresh air, plenty of ventilation, clean nest-boxes, and constant changes of nest, will do more to prevent their appearance than any other treatment.—W. A. B.]

THE CONTESTS OF QUEENS.

This is a subject which has been ably and fully discussed by Huber, but in making experiments to verify his statements the same results have not always followed. In introducing a fertile queen to a hive presided over by another fertile queen, he mentions that both the stranger and the reigning queens were immediately enclosed by the bees, and that the queens were virtually forced to decide by a single combat between themselves to which of them the throne should belong. Now, when introducing a queen to a hive in the circumstances mentioned, and without any strange bees accompanying them, I have never seen either the reigning queen encased, or the question of empire decided by a fight between the two sovereigns. The stranger queen has been invariably strangled by the bees of the hive to which she was intruded.

It is different when the subjects of a stranger queen are also introduced with her. Both queens are then encased, and a combat may, perhaps, take place between them, although I have never seen one. There are many apiarians who have never seen a deadly struggle between two queens. The late Dr. Dunbar was very anxious to witness a royal duel, but although he watched for one for years, he never had the good fortune to be a spectator of the conflict. Yet anyone who chooses may with very little trouble obtain a sight of queens in mortal embrace. Whilst admitting that the mother bee may and does occasionally put juvenile rivals to death when coming or about to emanate from their cradles, I imagine that fighting proper only takes place between virgins. As I have occasionally exhibited their encounters to friends, a description of the process followed may not be unacceptable to some readers of the Journal.

During the swarming season young queens are always plentiful, and two or three can often be found in a hive shortly after the issue of the second cast. Take two of these queens and with a hundred or two of bees accompanying each, put these miniature swarms in separate small boxes. Then towards dusk, when there is no danger of the bees taking wing, dislodge the two hives upon a large table near the centre, and about 1 foot apart from each other. The two clusters so dislodged break up, and their spreading circles are soon merged in each other. If the two queens are watched, it will be seen that they are comparatively placid so long as their presence is unknown to each other, but the moment the track or trail of one is perceived by her rival, the wings of the discoverer are raised, her pace is quickened as if in search of something, and it may be she will halt in her course and utter the piping sound heard previous to the migration of an after-cast. In a little while the queens meet, and if the opportunity is favourable a death thrust is given, generally by the stronger making a side embrace and curving her sting under the abdomen of the weaker. The disabled queen is then treated as a dying bee, dragged to the edge of the table, and thrown over.

About a month ago I had two young queens in my glass nicomb, the one dark and the other bright-coloured. The dark was slender-made, and the younger of the two. I happened to observe the first meeting of these princesses. There was first a sudden halt, then measured looks, then a rush by the dark one on to the top of the bright-coloured, the head of the upper being towards the extremity of the under. But the embrace lasted only a second or two, for the dark-coloured queen immediately quitted her hold and rushed in perturbation over the comb.

The fear awakened never left her, the slightest pressure of the crowd made her move precipitately. The light-coloured, on

the contrary, seemed quite at ease, and never once pursued her rival, but merely give a scowl at her whenever she approached too near. I watched the proceedings a whole day and saw the queens often meet, but the moment their antennæ touched, the dark-coloured fled apparently in great fear. The bees, however, contrary to Huber's experience, manifested no desire to make the two queens fight, they never once enclosed them or drove them together, neither did they display the least agitation. Ultimately, when darkness set in, the dark-coloured, as I expected, was slain by the light-coloured. "Coming events had cast their shadows before."—K. S.

MAIDSTONE AND MID-KENT NATURAL HISTORY SOCIETY.

At a recent meeting of this Society, the Rev. Walter Mitchell Vice-President of the Philosophical Society of Great Britain, gave an address upon the "Geometrical Structure of the Hive Bee's Cell." He said he had adopted the above title, as there were 250 different species of bees in this country, not one of which possessed the geometrical accomplishment and very peculiar construction adopted by the hive bee. This we called the domesticated bee, because it always followed in the steps of civilisation, or rather preceded them, for in North America the red Indian knew immediately the hive bee was established in the forest that it would be shortly followed by civilised man. The bee's cell was the most marvellous thing in creation, as far as our wisdom was concerned, in interpreting the works of the Creator, for those marvellous cells were made of a substance which it was extremely difficult for the bee to procure, and out of this substance it manufactured its houses, its streets, and its city. This city had three different classes of inhabitants—the queen bee, a few hundred males or drones, and several thousand neuters or working bees. He then pointed out that a bee on a given excursion fixed on a particular flower when it was collecting pollen dust, such as a wild rose or a lily, and visited those flowers only. The other bees collected honey for mixing with the pollen, and for the winter supply, which is put in the cells and sealed up. There was no creature whose habits the ancients were so fond of investigating as that of the bee—Virgil had written a great deal about bees—but none of them could tell from whence the bees obtained their wax. Some supposed that it was pollen, but on modern chemists burning it, they found that while pollen gave off an ash, wax gave none. This problem was, however, solved by John Hunter, the celebrated naturalist, who, on dissecting a bee, found that in the abdomen there were certain small bags containing a white substance, which, on burning it in a candle, proved to be wax, and it was, therefore, an animal secretion. The bee, therefore, had a chemical manufactory. He then described how the bees, during the summer months, gorged themselves with honey that this secretion might be produced.

In the construction of its cells from this substance the bee showed marvellous geometrical skill. Not only had the bee, led by its divine instinct, to gather honey and store it for the winter, when it knew it could get no food out of doors, but it exercised great economy in the use of that precious substance out of which it constructed its cells. The cells consisted of a great number of hexagons, or six-sided figures. The wasp, which had been a paper-maker since the creation of the world, made his paper out of wood, but he placed his comb, not vertically but horizontally. He made hexagonal cells, but he only made his houses on one side of the street—not back to back, as the bee did, and he simply covered in the bottom of his cell with a flat piece of paper. He displayed in this a certain amount of economy, but not the greatest amount of economy. The bees' cell, on the contrary, was terminated with lozenge-shaped bodies—like the diamond panes of a window—which, when they put their cells together, formed the bottom of a house, on the other side of the street.

The lecturer then described how the great French naturalist, Réaumur, by the aid of an eminent mathematician, discovered that the measurement of these cells by the differential calculus was exactly $109^{\circ} 28'$, and that they gave the greatest possible internal space with the greatest economy of material. The lecturer said, therefore, he concluded that we had not yet discovered the marvellous mechanism by which the bee produced this wonderful arrangement; and, with regard to the theory of natural selection, suggested by Mr. Darwin, he pointed out that the bee could not derive its instinct from its parents, for the working bees were neuters. The bees were wonderful archi-

From observations taken near London during the last forty-three years, the average day temperature of the week is 59.6°, and its night temperature 40.9°. The greatest heat was 80°, on the 14th, 1861; and the lowest cold 21°, on the 15th, 1860. The greatest fall of rain was 1.04 inch.

GRAPES FOR EXHIBITION.

On reading the proceedings of the Fruit Committee at the Royal Horticultural Society's Meeting, September 21st, page 226, I came to the conclusion that a few notes on early and late Grapes would not be out of place, and I invite the attention of the committees of horticultural societies holding their exhibitions in autumn.

I would make a distinct class for such fine exhibition Grapes as Meredith's Alicante and Lady Downe's among the black varieties, as, unless this be done, the different varieties of Hamburgs cannot have justice. I would also have a distinct class for the Muscats and Trebbiano among white Grapes, so as to give the Royal Muscadine, the Sweetwaters, and the like a chance of winning a prize.

In support of this view I would ask, Is the flavour of the Alicante and Lady Downe's in August, September, or October to be compared to the taste of the Hamburgs? Also, Is the flavour of the Muscats and Trebbiano to be compared with that of the Royal Muscadine or Sweetwater? These questions should answer themselves.

I do not for a moment wish to disparage the fine qualities of the Alicante and Lady Downe's, leaving out the newer late sorts, for I am perfectly aware of their usefulness, but I say they are not to be compared with the Hamburg for flavour now; and were the judges to taste, undoubtedly there would be many exhibitors disappointed, for, instead, as is generally the case now, of the award being given to the fine large bunches, well coloured though they might be, it would go to the Hamburgs, they being ripe and fit for table (or they should be so when shown), which cannot be the case with the Alicante and Lady Downe's. To me it seems a sin that such fine bunches as I have seen shown in September should be cut, for, the taste being insipid, they are worthless.

I am fully aware that Grapes must be ripened and coloured by the end of September or beginning of October, or they stand but a small chance of colouring, unless it should prove such a favourable autumn as the present. But Grapes require to hang a certain time after they are coloured. Thus, the Hamburgs coloured by the end of July are not ready for cutting till the end of August, and those coloured a month later are not at their best yet. Above all, the Alicante should hang till February to bring out its flavour, and the same applies, or nearly so, to the Lady Downe's. Of course, I do not say they cannot be eaten till then, but I do say they are not at their best till the time I have mentioned.

Next, as to the white Grapes. The Muscats are undoubtedly the finest winter Grapes for those who have vineries and heat enough for them, but their flavour in August, September, and October is not equal to that of the Royal Muscadine, Buckland Sweetwater, and Foster's Seedling. The Muscats require a high heat to ripen them, and they must be ripened early, but they should not in any case be cut before Christmas.

I now give the names of a few good Grapes, black and white, for exhibiting. Of the black, there is none to excel the Black Hamburg as a show Grape, but a far superior Grape for flavour, though ripening at the same time, is Pope's Hamburg [Frankenthal]. This is a beautiful Grape, and no one should be without it where quality is considered. It has a very thin skin, a delicious flavour, and will hang till Christmas without deteriorating. Trentham Black is also good for exhibiting, but unless ripened, say, in July, it should not be cut till November; in fact, this is the best of the Hamburgs for keeping.

Of the whites, the best early is the Royal Muscadine. This is a very early Grape, and a good keeper. Ripened in a late house it will hang well till Christmas. Foster's White Seedling is also a keeping Grape of good flavour. All the above can be grown well with ordinary care and with but little fire heat.

The Alicante and Lady Downe's are both too well known to say more than that they are (leaving out the recent additions, such as Mrs. Pince), the best late Grapes, but they are not fit to be exhibited till the new year comes in, because, till then, we have plenty of far superior-flavoured Grapes, and no matter how fine a bunch of Grapes may look if they are acid or inferior to the palate. The Muscat of Alexandria, Trebbiano, and White Lady Downe's are, as I said before, good for late work, till then there is nothing to equal the Muscadines or Sweetwaters.

As it is now some time since I saw this subject discussed, I hope this short paper will be the means of eliciting a few remarks from some of your correspondents.—STEPHEN CASSELL, *Bent Hill Gardens, Prestwick.*

POTATOES.

THE Potato is, undoubtedly, one of the most important and valuable of all crops to those who are fortunate in having a piece of ground for the growth of vegetables; and I am one of those who do not believe there can be a home in the country without a nice little garden in front for flowers, and a plot of ground for the growth of vegetables. I believe if there were more gardens, one at least to every dwelling, that the beershops would have little charm for the hard working labourer, much less for the skilled and comparatively well-to-do artisan. There is not a creature on earth but has a liking for—a love of—plants, who does not delight in flowers, fruit, or vegetables; and there are none so ready to manage well the plot of ground they may have as those who by some means must, if they are to appear decent and respectable, keep from at every meal cutting at the bread loaf. It would be well if every house had its garden. It is a mine of wealth that none know the value of better than those who once possessed a garden, but who, unfortunately, have a house (it is no home) without one. Do not understand me as advocating a large garden to a cottage—one that has a large assemblage of fruit trees, of which the occupier may be heard to boast that this or that tree pays the rent. I believe large gardens to cottages are generally neglected. The occupier finds a large garden too large for what he

needs in the way of vegetables, and he plants it with standard Apple, Pear, and Plum trees in the hope of some day getting enough fruit to pay the rent. The trees grow, rendering the ground totally unfit for vegetables, and soon become an orchard of trees that need no looking after, and with them the greater part of the interest is lost. Some part of the ground is turned up, kept for growing Potatoes—they are indispensable—but they are often not worth taking up, and he grumbles at the work of his predecessor's hands. Fruit for small gardens is all very well, but it fills no gap like Potatoes and vegetables generally, nor is it nearly so needful for health.

In small gardens, however, there is no reason why fruit as well as vegetables should not be cultivated well and in quantity sufficient for the wants of a cottager's household; but it must not be sought by planting trees that, when full-grown, will render useless as much ground as would be required for the growth of enough of both to meet all the requirements of the family. Should the cottager, fortunate in having a plot of ground, rest content with only vegetables? By no means. On the contrary, let him have his Gooseberry and Currant bushes, and his bush or pyramid Apple and Pear trees, with Plums, all of which bear excellently in that form, and being always of reasonable proportions, do not render the ground unfit for anything except grass and weeds, as may be seen in many places besides Kent. The value of such trees is not known half so well as it deserves to be; indeed, I am convinced that a future generation will not retain, much less plant, a plot of ground with standard Apple, Pear, and Plum trees; for anyone who has planted both cannot but be surprised by the greater benefits offered by bushes and pyramids than by standards. Like standards, all bush and pyramid trees are not fruitful, but some kinds are extraordinarily prolific, affording more fruit, and of a finer quality, in three years than a standard in seven, and always as much in proportion to the ground occupied. I hope Mr. Rivers will favour us with an account of the most suitable kinds of Apples, Pears, and Plums—those affording the greatest quantity of the finest fruit, and with the greatest certainty. This would give an impetus to fruit culture in small gardens, the owner and family having within their reach fruit of the best out-door kinds, both as regards quantity and quality. I shall refer to the subject of fruit for small gardens at some future time, and I should not have alluded to it at present, but my object was to show the detrimental effects of large fruit trees on ground required in part for vegetable crops, and especially Potatoes.

It is a common error to suppose that good Potatoes cannot be grown in gardens. The ground is considered too rich, or it is said from some other cause they are indifferent in quality; but I have been a grower for upwards of twenty years, and am satisfied that they can be, and are, grown well in all gardens where the requisites are afforded. In many so-called gardens, which are in fact orchards, they do not thrive, nor can they be expected to do so, for the fruit trees shade the ground too much, and Potatoes, with vegetable crops of all kinds, endure least of all a rival. Open spaces are required for Potatoes; in no other can they be successfully cultivated.

An open situation, as I have stated, is necessary—one not shaded by trees, which are objectionable in several ways; their roots are quite as injurious as their heads, and they dry the ground in summer. There is nothing beyond this to hinder the cultivation of good sound Potatoes in gardens.

Next to the situation, the ground is the most important consideration. Almost every description of soil will grow this crop, but there can be no question that some soils are better suited to it than others; and yet this ought not to deter those with soil not so favourable from growing this most important tuber. Any soil may be made to meet all the requirements of the Potato, but first of all the ground must be drained; secondly, it must be brought into "good heart" and tith.

The ground should be well and deeply dug in November, and thrown up as roughly as possible. If at all heavy it is well to throw it in ridges, the narrower the better, so as to expose it to frost as much as possible. If it has not been trenched it would be well to do so, not bringing up too great a depth of the subsoil, if the latter is of a stiff inert description. Soils which have long been worked become when trenched almost as good as fresh land. If the ground is rich and full of vegetable matter or animal manures, no manure need be given. There is ground in gentlemen's gardens quite rich enough for Potatoes, but it is seldom so in small gardens; therefore, in digging give a good dressing of manure, preferring that which is fresh. It is wasteful to throw dung and litter in heaps to

ferment, driving off its most fertilising principles. Litter as it may be, dig it in during November, or, if the ground is to be trenched, place the manure between the bottom and top spit. It will rot in the ground, and it is an error to conclude that its manuring properties are washed out and carried off by rains. The soil has a remarkable power of seizing on ammonia and other important substances, which to a great extent are dissipated in a heap of heating and fermenting manure. I am convinced, from the great benefits of spreading fresh manure on the ground as mulching, that the system of manure heaps is an error. Decayed manure is very portable, and in every way more easily applied than fresh manure, but I am certain that one load of the latter is a greater stimulant to growth than two of that which has been thrown in a heap and left until reduced to a soapy mass, and it will cover twice as much ground. It is a fact also, that ground which has been turned up and exposed to the atmosphere increases in fertility, whilst ground left between crops to grow nothing but weeds, and with the surface close and firm, forms but a very indifferent medium for the succeeding crop. We often see ground left undug until it is wanted for cropping. Cottage gardeners and occupiers of small plots rarely dig until it is time to crop. It ought to be dug and manured as soon as each crop is off, so as to be ready whenever required. For Potatoes, as I said before, the ground should be dug and manured in November, and if possible in dry weather, and it will be more benefited than it would be by two or more diggings in spring. The frost will make the clods fall down, and greatly improve the soil's fertility.

In February, or if hard frost or wet weather occur, then in March, turn the ground over with a fork, and if it has been ridged up, level the ridges, giving the whole an even surface. All hard lumps of soil should at the same time be broken small. The soil being turned up early in spring it will soon be in a good condition for planting, and in no case ought this to be attempted when the soil when trodden on becomes a close, heavy mass which adheres to the feet.

Before planting we must consider the seed and the kinds. Of the seed, or sets, I would say, let them be of fair size, and as uniform as possible. If there are different sizes, plant each size by itself to secure that uniformity in the haulm which is pleasing to the eye. I admire nothing so much in Potato crops as regularity of growth. Some advise small sets, and, if the seed Potatoes are large, cut them to pieces; but I like a good set, and whole. I would not have sets weighing less than 1½ oz., nor need they exceed 3 oz. in weight. If the sets must be cut do not do it too hard. A cut set should be somewhat larger than a whole one. Select the seed from ground at a distance from that which you intend planting, and of a different kind, doing this every second, or at most every third year. See that the sets are sound, and if possible make sure that the first sprouts have not been previously rubbed off. Make sure of these; none are so good, nor will any afford such fine strong haulm, and fine, even-sized tubers. To prevent sprouting it will be necessary to keep the tubers cool in winter, but safe from frost. This is a very important matter, and one very much neglected.

To secure regularity in the crop, let the sets be placed thinly in boxes or hampers, or on a floor, at least a month before planting, and the place need not be a very warm one, for if the early kinds make sprouts from half to three-quarters of an inch long, and the second earliest sprout enough to exhibit their activity, it is sufficient. Long sprouts are so liable to be knocked off, that they are often a source of injury instead of being a benefit. I would plant none but those which show signs of growth.

With regard to varieties, I am very diffident about saying anything, as I consider there has been but little advance of late years, except in coarseness. Quality has not been sufficiently considered, therefore I may be excused if I still adhere to the old sorts. The new kinds have too much top, are too large, and have very large, deep-sunk eyes, causing much waste. Of very early kinds, there is none to beat the old Ashleaf Kidney. It is the best earliest sort for frames and the garden, but it is not a very heavy cropper, and must have prominence only for its earliness. Of this there are several so-called varieties, but all that I have grown have proved merely well-selected stocks.

Myatt's Prolific is a very fine prolific kind, much more so than the Ashleaf, and succeeding it by ten days. Except for very early crops this ought to be made the early kind, enough of the Ashleaf being planted to afford a ten-days supply. The Launceston is the best of all Potatoes, taking production and quality

into consideration. It succeeds Myatt's Prolific, and continues good longer than most varieties. It is a very weak grower in its early stages, and is tender on heavy, wet soils, which are not suitable to it; light and medium-textured soils are the best for it. Huntingdon is not unlike the Lapstone, but is a larger kind, many of the tubers weighing upwards of a pound under ordinary circumstances. It is not so tender as the Lapstone, and is better for heavy soils, otherwise it is inferior to the Lapstone. It is also later. Sultan is a pink Kidney; indeed, a pink Lapstone, having all the good qualities of the latter, and none of its defects, so far as I have experienced; it is not liable to disease, and is a first-rate keeper. The above are all Kidney sorts.

Of the Round kinds, Early Oxford is a second early, succeeding Myatt's Prolific. It is an excellent cropper, of good quality and size, but has the drawback of forming deep eyes; nevertheless, it is excellent from July to November, or later. Regent is, in my opinion, not superseded as a late Round sort, quality and productiveness being considerations. Fully two-thirds of the white Round sorts are like the Regent under different names.

The above are all the kinds I grow, or can see the advantage of growing. There are, no doubt, many others which will pass muster, yet I think the fewer the kinds grown the better, for there is the trouble and annoyance of having kinds which are often desirable only for affording a slight and not unfrequently supposed variation.

As respects planting, the ground being prepared as already described, the rest is easy. The line is stretched lengthwise or across the plot of ground, allowing from the outside of the plot half the distance the rows are to be apart. With a spade take out a straight trench 3 inches deep; in this place the sets, and cover with the soil from the next row. They need not be covered deeper than 3 inches, so that a wide trench is altogether unnecessary. If large enough to receive the sets at the proper depth, it is enough. For the Ashleaf I allow 2 feet between the rows, and place the sets 10 or 11 inches apart. To Myatt's Prolific I give 2 feet, placing the sets 1 foot apart in the row. Lapstone, Huntingdon, Sultan, and Early Oxford are allowed 2 feet 6 inches from row to row, and are planted 1 foot apart in the row. I like the rows to be a good distance apart, but to be so planted that the fork can hardly be got in, when taking up, without feeling the Potatoes. All the late sorts are allowed a yard between the rows, and the interval between the sets is 15 inches. Thus they form a mass of Potatoes. Some sorts I have grown would do well with an interval between each other in the rows equal to half the distance that the rows are apart, many being all top.

As to the time of planting, that will depend on the weather. Some have fixed times of planting, but there is no advantage in planting when the ground is wet and cold. The Ashleaf I like to have in by the third week in March, Myatt's in the fourth week, along with the second earlies, and the late sorts by the second week in April; but I would rather defer the planting a week or ten days than plant with the ground wet and cold. There will be exceptions to these times of planting as regards the early kinds in warm situations, but in open though not very much exposed situations I find the times stated sufficiently early for safety from frosts, whilst ensuring a good growth before hot dry weather sets in, and as a consequence the produce is good and well matured long before the autumn rains—a point I hold to be of importance.

The after-management consists in hoeing between the rows as soon as any weeds can be seen, and when the tops are 6 inches high I earth well up. I am aware some do not advise earthing-up, but I find that where it is not practised many green-ended tubers unfit for human food are produced; besides, they do not attain so large a size. The wider the rows are the better. A deep wide furrow between the rows is injurious by drying the ground, and preventing the rains from wetting the soil for a time after dry weather.

After the earthing-up no further care is required. The haulms will grow and keep under all weeds, but should any gain a hold, pull them up. As soon as the haulm turns yellow, the crop should be taken up and stored. It would be well if the tubers could be placed in a cool dry shed, but they should be kept dark. Light will cause them to become green, and they are then unwholesome. After they are dried no plan is so good as pitting. They keep most plump that way. For the pit a dry situation should be chosen.

Before closing, a word about cooking Potatoes. There is no mode equal to washing them clean, and then boiling them

until soft through; then strain off the water, and place them on the fire a minute or two until the water is dissipated, and finally peel either as you require them for eating or just previously. It is the most economical way of cooking, and the only one in which the full flavour is preserved. By peeling beforehand, and steaming or boiling afterwards, much of the best properties of the Potato will be carried off by the steam and water. The latter may be considered a cleaner process, but Potatoes cooked unpeeled will go nearly twice as far, and are fully twice as good.—G. ABBEY.

BEEF FOR ORNAMENTAL PURPOSES— STORING BEET.

ALLOW me space for a few notes upon the Red Beet's treatment here this year. The seed was sown on the 6th of April in a box placed in a pit heated by a flue. The seedlings were pricked out into other boxes when fit to handle and returned to the pit, where they were kept until well rooted. I then placed them in the open air in the shade, fearing that the sun would burn and spot them. On the 1st of June they were nice plants, and were planted out in the centre of two large beds to match, with two rows of Cloth of Gold Geranium all round, and bordered with two rows of *Lobelia speciosa*. The Beet is now a rich dark bronzed purple. Growing in rich ground it is not more than from 9 to 10 inches high, not one of the plants running to seed.

I think Dell's Beet should be a boon to the flower garden. Last year it stood the whole winter in the ground without any protection, still holding its leaves and looking very fine in the spring. What can be better in the way of foliage for the spring garden? Of course we cannot have *Iresine*, *Amaranthus*, *Coleus*, or *Perilla* in the spring garden.

I have this year a quantity of blood red *St. Osyth* Beet in the kitchen garden as good in colour as Dell's. There is more scarlet in its leaves than in Dell's, which causes it to glitter when the sun shines upon it, but it is not nearly so good in form as Dell's.

The best way I find for storing Beet for table use is in heaps in the open air covered with earth, which prevents it shrivelling or drying up, as it would do if it were kept in a dry shed or loft. I have had it here in good order for the table until the middle of July.—J. W., *Corwahn Gardens*.

ORCHARD-HOUSE EXPERIENCE.

I SUPPOSE there is hardly any subject which does not admit of argument both for and against. It must be so in a world where nothing (not even fruit and flowers) is quite perfect. Thus it is small matter of surprise that there should be much variance of opinion upon the subject of orchard-house culture. This, no doubt, in common with other questions, has its pros and its cons, and the wise man is he who, with impartial judgment, setting the one against the other, aims at striking a fair balance between the two; whereas the man of narrow mind, leaning to one side only, becomes, like the reader of a single newspaper, either a too zealous partisan or too bitter an opponent. Now, I will confess at the outset that, after several years' experience, I am an advocate for growing fruit under glass, but though an advocate, not one of such ultra views but that I see the expediency of aiming at the happy mean lying between the two extremes of opinion upon this matter.

Now, at the risk of provoking a smile from some of your readers, I will try to illustrate what I mean by striking a balance between the *pros* and the *cons* as regards orchard-house culture by referring them to Tupper's lines descriptive of a baby. A baby, like orchard-house culture, has its *pros* and its *cons*. It gives you smiles, but also wry faces; it crows, but it cries; it is a great comfort, but an unmitigated nuisance at times. Upon the whole it is a desideratum. But to my quotation—

"A babe in a house is a well-spring of pleasure,
A messenger of peace and love, a resting-place
For innocence on earth, &c."

An enthusiastic commencement, truly! So far the *pros*, if I may venture to apply so equivocal a word to *poetry*, seem to have it all their own way; but stay! mark what follows:

"Yet it is a talent of trust: a loan to be rendered back with interest:
A delight, but redolent of care; honey sweet, but lacking not the bitter."

All this is a true description, not only of a baby but of an orchard house. It is "a well-spring of pleasure," especially

when provided with a tank that would not run dry during such a season of drought as the one from which we are but now emerging. At all seasons—potting, blossoming, fruiting, stoning, growing, ripening, gathering—the orchard house is a well-spring of pleasure, a pleasant lounge, a pleasant divan, a pleasant scene of labour, not irksome, but like that of Eden—

"No more toil
Of their sweet gardening labour than sufficed
To recommend cool Zephyr, and made ease more easy."

A pleasant place of retreat (except when the sun is a little too warm) from the cares and business of life. It is, moreover, "a resting-place for innocence on earth." Yes, for innocence! Don't laugh! Orchard-house pleasures are innocent pleasures, and only to be truly enjoyed by innocent people. Surely if Izack Walton had a right to assume that all brothers of the rod were honest men, I may claim equal license to assert that my brother fruit-growers-under-class are innocent men. You cannot call anglers innocent. Gudgeons know them to be full of guile; but all of our craft, Messrs. Editors, are free from guile, and honest men to boot; and so, according to the inexorable logic of facts, as Count Bismarck would say, the orchard house is "a resting-place for innocence on earth." But now *audi alteram partem*. "Yet it is a talent of trust." Yes, here it is that so many make a mistake. Some wealthy proprietor of greenhouses and vineries must have an orchard house also. As he likes to have everything very nice he grudges no expense, thinking that, as a matter of course, abundance of fruit will result from a considerable outlay. The crystal palace is reared—a thing of beauty and a joy for ever; but he takes no pains about the selection of his trees, or potting them in a suitable soil; he never troubles himself about pruning, pinching, fumigating, lifting, watering, syringing, mulching. All that he leaves to his gardener, who has plenty else to do; and when he thinks, good easy man, full surely his Peaches are a-ripening, on inspection he finds his unhappy pyramids poisoned with aphides, or over-run with red spider, or starved for want of nutriment, or withering away from lack of moisture, or redundant with leaves from want of pinching and thinning, and no good joint coming to perfection. He either lays the blame upon his unlucky gardener, or else joins in the hue and cry that orchard houses are failures—all humbug—expensive toys—all very well for those who sell the trees, but of no profit to those that buy them, and so forth, forgetting the axiom that the orchard house "is a talent of trust"—a talent to be improved by himself, not delegated to another—"a delight, but redolent of care." Ay! mark well that formula, "a delight, but redolent of care." To be the former it must be the latter also, for without care—care incessant, personal, and loving, no orchard house, however costly, can possibly succeed. Yes, it must be redolent of care—not anxious, troublesome, carking care, but care that is pleasant, as all gardening care is, because full of hope, full of promise, sure to be rewarded; for has not the Giver of all good things made man's success to depend upon his endeavour, and as good as promised that "we shall reap if we faint not?" Want of personal care, and supervision, and interest lies at the root, depend on it, of all want of success in orchard-house culture.

I will only just add that, although the late season has been fruitful, yet in consequence of the long drought, out-of-door Peaches here fell from the trees before they were fully ripe, and that the fruit grown inside the orchard house has been far superior. We have had a plague of flies this autumn, and I intend bringing up my siege guns in the shape of Appleby's fumigators, of which I highly approve. I find it a good plan where Vines are trained beneath the rafters to have early Apricot trees in pots, because they are well advanced before the Vines put forth their leaves, and they can be easily moved if necessary to ripen their fruit in the open air; but then I have 108 feet of wall 13 feet high well covered with triple cordons, which supply me with abundance of Peaches and Nectarines.—A CONSTANT READER.

THE BERR KNOT APPLE.—This valuable kitchen Apple, I think, owes to us from the north. It has not the least resemblance to the English or any other Paradise stock, has large leaves, and large fruit of excellent quality good all the autumn. I find it in the "Catalogue" of the Horticultural Society, 1831; but I do not find it in the "Fruit Manual" by Dr. Hogg. In most cases it grows from truncheons planted in the ground, and it bears fruit the second year after being planted. It is, I believe, used as a stock in some places. Most of our

fruit-growing nurserymen know this Apple well.—CONSTANT READER.

COMPARATIVE PRODUCE OF POTATOES.

For the following report of results we are indebted to Admiral Hornby, Knowsley Cottage, Prescott, Lancashire. He thought that seed obtained from other localities and new varieties would be more productive than seed grown near Prescott and of older varieties. He also tells us that "of the sorts I send you, there is not one bad sort, but as to their keeping powers I have yet to see. The various sorts have been all treated exactly the same, and grown in light black soil."

GIFTS OF BEDDING PLANTS.

At this season of the year in all large gardens many hundreds of fine bedding plants must be cleared off and committed to the limbo of the rubbish heap—a sad end to come to after affording so much delight. Would it not be better if they were given away to our poorer neighbours? This is done by public announcement in the case of the parks in the metropolis; can it not be imitated by private individuals in the suburbs of large towns?

What visitor to those lanes and courts will not bear willing testimony to the good effect, the quiet influence, of some well-kept window garden on the sunny side? Those painted boxes, those clean red pots, the plants without a dead leaf or withered branch, prove that there is no slatternly wife, no drunken husband within. The same care that attends to these objects will also see that there are no dirty windows, no filthy doorstep, no unwashed floor, and no uncombed children. From railway arches, too, are to be seen little oases in back yards, and wondrous parterres on housetops. Fevers are infectious; but the love of plants, the rivalry of bloom, and the accompanying habits of neatness and decency are infectious too, and we can powerfully second the efforts of those of our sisters and wives who visit the poor, by a distribution of plants in autumn and of a few pinches of seed in the spring.

Of course there will be a little trouble and some loss of time for the gardener, but a notice hung outside the gate to the effect that on a certain day plants will be given away on application will render the matter easy enough. I thus distributed last year from my small garden upwards of two hundred plants—*Calceolarias*, *Geraniums*, *Verbena*, *Heliotropes*, *Gazania*, &c., each of which would make several fine cuttings. Many large establishments must have cartloads of these, besides a surplus stock of *Crocuses*, *Snowdrops*, *Gladioli*, and other bulbs. If you think this communication likely to be of service in inducing anyone to try to do good at little expense, perhaps you will find a corner for it.—PENUMBRA.

ERADICATING WEEDS WITH CREEPING ROOTS.

In a recent number I saw a query from a correspondent respecting the possibility of banishing Couch and Bindweed. I have had, I regret to say, some experience of both, and consider it quite possible to banish them, the first step being to forbid the use of a spade, nothing but a fork to be used. One year my Asparagus bed was so full of Bindweed that it seemed as if the Asparagus had been grown merely as stakes for the

Bindweed, the crop being, as you may imagine, *nil*. I took it in hand myself, carefully followed every plant with a fork, and took up every root I could find; when this was done I gave the bed a good salting. I had a fine crop of Asparagus; of course a good many plants of the Bindweed came up during the summer, but these were forked up when they appeared, and now there are but few remaining. I think the salt killed much of the weed, as I found many blackened roots. I am now hard at work at the Strawberry bed, where the Bindweed is in quantity.

Another hint—when forking out the roots let them be at once put into a basket and no other weed put with them, and if the weather be dry let them be burned without delay. As every little piece grows and is thrown into a heap with other weeds, the supply will be increased.—AN OLD DUBLIN SUBSCRIBER.

PROTECTING THE BLOSSOMS OF WALL-FRUIT TREES.

I HAVE long entertained the opinion that a constant current of warm air passing over wall-fruit trees would be an effective preservative of their blossoms from frosts and cold winds. The only experiment I have been able to make testing my opinion was by placing a closed tin vessel at the foot of a wall, and filling it with boiling water. A thermometer hung against the wall, and 4 feet above the vessel, registered 30° of Fahrenheit's thermometer—or 2° of frost—before the boiling water was poured into the vessel. On this being done the thermometer began immediately to rise, reached to 40°, and never varied from that during the hour I continued the experiment. An easterly wind was blowing briskly, and I poured into the vessel fresh boiling water at intervals, so that its average heat was about 200°. Now this experiment and the geothermal experiments I saw in operation at Major Trevor Clarke's and elsewhere, justify the opinion I entertain. Unfortunately, at present, I have no means of practically testing its soundness, but I will state the mode in which I would test it, and, perhaps, some of your readers will give it a trial.

This represents a 3-inch flow and return pipe in a bricked gutter at the foot of the wall. The flow-pipe should have a valve to shut off its communication with the boiler, for the hot water would only be needed during the blossoming season. The return-pipe also should have a similar valve, but with a tap outside, so that the pipes might be empty during winter to avoid injury by freezing.—G.

ORCHARD HOUSE PRODUCE.—In an orchard house on a south wall we have a small Pear tree, Benrè Diel, on which grew three Pears. I weighed them when taken off, and I give the weights respectively:—One exactly 1 lb., one 14½ ozs., one 13 ozs. All were handsome. The house was put up last spring, and the tree was planted during March. We have had five Peaches,

Plums, Pears, and Nectarines in abundance, without overcropping, yet we have no fire heat of any kind.—A LADY SUBSCRIBER *Kirkcudbright, N.B.*

RIVERS'S SEEDLING PEACHES AND NECTARINES.

I HAVE grown and fruited in pots this summer some of Mr. Rivers's new seedling Peaches and Nectarines, and I have found the following varieties to be great acquisitions as regards earliness and flavour. They were grown principally on a glass-covered wall, but a few of the varieties were fruited on a south wall without protection of any kind.

Amongst Peaches the Early Beatrice was the earliest in ripening, being quite ripe by the middle of July; it was juicy in texture, and the flavour was good. Early Louise ripened about the end of July, but was not so juicy nor so good in flavour as Early Beatrice. Early Rivers ripened with me about the same time as the Early Louise and was very juicy, with a rich, racy flavour. Dagnar proved to be a large and finely-coloured Peach, and ripened in the second week in August. Dr. Hogg, another large and also a finely-flavoured Peach, ripened about the same time as the Dagnar. Early Silver, a very large and highly-flavoured Peach, ripened in the third week in August. Alexandra Noblesse has quite the pale colour of the old Noblesse, as well as its juicy and rich flavour; it ripens in the end of August. Lord Palmerston is a very large, pale Peach, and is at this date (September 15th), ripe, but the flavour is not first-rate. Princess of Wales is another very large Peach, pale in colour, with rosy cheeks next the sun, but it will be the end of September before it is ripe.

The order of ripening of Mr. Rivers's seedling Nectarines was as follows:—Lord Napier, a pale-coloured Nectarine of good flavour, and ripening in the beginning of August. Rivers's New White is better flavoured than the Old White, and ripens in the middle of August. Rivers's Orange, a seedling from the Pitmaston Orange, is an excellent high-flavoured variety, and ripens in the end of August. Stanwick Elruge has a smack of the Stanwick flavour in it, and ripens in the end of August. Victoria, the latest of Mr. Rivers's seedling Nectarines, is very rich and juicy when grown in pots, and ripens from the end of August till the middle of September.

Dr. Hogg Peach has ripened with me on a south wall, and was in season in the end of August; it is a variety of excellent flavour. The Pine-Apple Nectarine has likewise ripened on the same wall, and is an excellent new variety, the flesh yellow, like Hunt's Tawny, very rich in flavour, and the colour of the fruit nearly black next the sun.—WILLIAM TILLEY, *Walsbeck.*—(Florist and Pomologist)

ARKLETON.

THE railway traveller on reaching the city of "fair and merry" Carlisle has every opportunity and inducement held out to him by the convenient and numerous despatches of railway trains in all directions, by the excellent hotel accommodation, and by the kind and hospitable disposition of the people, to "break his journey" at the "border city." He will find here spots hallowed by associations with the past, which must ever remain dear to all lovers of history, archaeology, and romance. He will find a clean, well-built town, situated in one of the most pleasant and fertile-looking districts in the north. He can see the ruined castle whose rent and mouldering battlements still stand as silent sentinels, holding watch over the broad vale of the winding Eden, the silvery Solway, and the dear, old, brave Scottish border land. He may recall to memory the dark days and scenes of early Norman rule, when this time-battered fortress was founded by William Rufus, and how in succeeding ages it became the dwelling-place of David I. of Scotland, and the refuge and prison-house of the misguided, ill-fated Mary Stuart. He can wander in the choir and aisles of the grand, old, massive cathedral, and survey the decorated eastern window, pronounced by many to be superior even to the magnificent western window of York Minster. He can get a railway ticket, as I did, and leaving keep and castle, Kirk and cathedral behind him, travel for upwards of an hour through one of the finest-wooded, prettiest routes in Scotland. My hour's ride by rail landed me in the small, beautifully-situated, thriving, manufacturing town of Langholm.

But as I was in search of gardeners and their gardens rather than in quest of "wabsters and their clouts," I hastened

through the dirty, ill-paved street, and soon found myself in the policy grounds surrounding Langholm Lodge, one of the Duke of Buccleuch's shooting-boxes in Eskdale. The grounds, and especially the woods, reflect the highest credit on the good taste and judgment of the officer who manages them; but the gardens, both in arrangements and productions, are quite unworthy of their natural situation and their noble proprietor. In wide contrast to them were the well-planned, neatly-arranged gardens and vinerias at Arkleton, the residence of John Jardine, Esq., situated in one of the most picturesque parts of Ewisdale, about five miles from Langholm, and 450 feet above the level of the Solway. These gardens show at a glance the intelligence of the gardener and the liberality of the proprietor.

Arkleton grounds and gardens were planned by my old friend, the late Mr. Little, of the firm of Messrs. Little and Ballantyne, of Carlisle, and were executed by the present gardener in the years 1863 and 1864. Having heard that the gardener had acquired considerable fame as a grower of Grapes, Peaches, and Nectarines, I at once made my way to the vinerias. I found these to consist of two houses (Shaw's patent), each 30 feet long. I found the Vines were Black Hamburg, Millhill Hamburg, Golden Hamburg, Black and White Frontignan, Buckland Sweetwater, Muscat of Alexandria, Tynninghame Muscat, Archerfield Muscat, Mrs. Pince's Black Muscat, Black Alicante, Lady Downe's, and Syrian. I give the list in full, as possibly it may be of use to some amateur Grape-grower. I was credibly informed that all these Vines had been heavily cropped from the second year of planting, some five years ago, and that the average weight of the Black Hamburgs had been 2½ lbs., Lady Downe's 3½ lbs., and Muscat of Alexandria 3½ lbs. I was chiefly anxious to see the Syrian Vine, on which had been grown the marvellous bunch, 19 lbs. 5 ozs. in weight, which created such a sensation at the Show of the Royal Caledonian Horticultural Society, held in Edinburgh on the 7th of September last. This Vine has carried since it was planted in 1863 fourteen bunches, the heaviest weighing respectively 6½, 7, 8½, 16½, and 19 lbs. 5 ozs. The Vine is well trained, and is growing vigorously. I measured the wood of this year's growth, and found it was 3 inches in circumference. The old wood was 5 inches in circumference, and the leaves 19 inches by 15. It is highly to the credit of Mr. Dickson to be able to show such a plant, and to point to it as the bearer of the heaviest single bunch of Grapes ever produced in Great Britain, surpassing by 5 ozs. the famous bunch recorded by Speachley.

I made a short visit to the Peach and Nectarine house, and found it 180 feet long, with a drum trellis running along the front, and occupied with well-grown, healthy-looking, fruit-laden trees, among which were all the leading sorts in cultivation.

Altogether, my visit to Arkleton was a very pleasant one; nor less pleasant was my drive to Longtown through the wooded glen leading through the beautiful parish of Canonbie, and past its peaceful hamlets, its trim, well-furnished wayside cottage gardens, its elegant school-room, and its unobtrusive-looking church. I thoroughly endorse the opinion of Kohl, who declared that amid all his wanderings he never journeyed over a more lovely road than that which lies along the windings of the "wooded Esk" from Langholm to Longtown.—*BETA.*

CUTTING PEACH TREE LEAVES.

Will your correspondent, the Rev. W. F. Radclyffe, say upon what principle in physiology he bases his plan of cutting off the leaves of Peach trees to cause them to ripen their wood more perfectly? I have always been a great advocate for getting as much healthy foliage as I could on all kinds of plants, so as to produce the best type of healthy wood, and have hitherto considered the pulling-off the leaves before they had completed their functions to militate against the ripening of the wood, and consequently against the production of fine fruit. As with animals so with plants; if you wish to preserve them in health and to hear healthy produce you must endeavour to keep all their organs healthy, and not deprive them of what is necessary for the perfect development of their nature. If we wish to limit the size or surface of a tree we must withhold the food, this is the only check Nature will admit.—*J. SCOTT, Merriott.*

[In answer to Mr. John Scott, until fruit is off, and until September and October arrive, I should think it very far from in accordance with physiological principles to cut the leaves in half; but when, as here now, the triple buds are all formed and the fruit removed, I see no harm in cutting in half the

leaves. My trees, from disabbing so little, are now better-foliated than those of most people in the height of summer. I have a great many Peaches and Nectarines on west and east aspects; the former only receive a back and afternoon sun, and the latter only a morning sun and a little midday sun. It is, therefore, of importance to let in the sun and air to the wood after cropping is over, to harden and ripen it. I quite agree with Mr. Scott that good leaves are essential to fine flavour and the general welfare of the trees. I see many insects on my leaves, and by cutting them in half I am enabled to wash the insects off. If the fruit is gathered, people should follow up red spider, thrips, scale, and aphides till all are destroyed. I never saw a finer sight than the Peaches and Nectarines here this year.—*W. F. RADCLYFFE.*]

POMOLOGICAL GLEANINGS.

PEAR BRILLE ROUENNAISE.—Amongst the never-ending streams of new Pears, here is one which stands well forward. It ripens, it is true, at a season (October), when we have quite a glut of good fruits. In appearance it is very handsome, being of a rather long pyriform shape, tapering very much to the stalk, which is long and slender. Whilst hanging on the tree it is particularly graceful. The eye is closed, set in a very shallow depression; the segments of the calyx long, erect, and pointed. The skin is pale green, changing to pale yellow as it ripens, tinged a little on the exposed side with numerous minute crimson specks. The flesh is white, very buttery, and melting, very rich and sugary. Altogether first-class.

—**PEAR AVOCAT ALLARD.**—This is one of M. Grégoire's very numerous seedlings, and promises well. In quality it is quite first-rate. The fruit with us this season is rather small, but it looks as if it would grow to a goodly size. The flesh is pretty solid, a little soft; flavour very rich, with a strong muscat aroma. Season, October. We mark this as a promising variety.

—**PEAR HENRI NICAISE, HELIOTE DUNDAS.**—We grow the same Pear under both names, and must speak in high terms of its praises. In appearance it is fully more beautiful than the Forelle, or Tront Pear, which is so well known; it is of far higher quality, and the tree is more hardy, as it bears well as an open pyramid, which the Forelle does not. The fruits of Heliote Dundas are rather over medium size, obovate, beautifully flushed and streaked on three-fourths of the surface with brilliant crimson. The flesh is tolerably firm, yet melting and juicy, sweet, and rich. The tree bears profusely as an open pyramid on the Quince stock, and the fruit commands a high price in market on account of its handsome appearance.

—**APPLE SUMMER THORLE, OR WHOLE PIPPIN.**—We were lately extremely pleased to meet in Ireland with this old and particular favourite of ours, and to find it was so much cultivated and so generally esteemed. It is one of the first Apples we knew in our schoolboy days, and right well was it relished then; never, we believe, have we tasted Apples half so sweet, and even now there is a certain charm, a certain smack about this particular Apple which no other has. It is decidedly the best summer Apple of the north, both in Scotland and in Ireland, yet, singularly enough, it is seldom to be met with in the south, or in the neighbourhood of London. It is a very hardy variety, and a most certain and heavy cropper even as an open standard in the north of Scotland. The fruits are rather below the medium size, quite flat, like the Osain. Skin very clear, beautifully streaked with bright scarlet on the exposed side, and altogether very pretty. The flesh is white, quite crisp, juicy, and refreshingly sweet. The fruits are generally very uniform in character and quality. It is in use during August and September, and is best when gathered off the tree, or very shortly afterwards. It is an Apple much to be recommended, but greatly neglected.

ECKLAND VALE APPLE.

In page 268 information is wanted regarding the origin of this Apple. Ecklinville Seedling is the proper name of the Apple. It was raised from seed by the then gardener, probably more than half a century ago, at Ecklinville, a gentleman's seat about eighteen miles from Belfast and four miles from Portaferry. I saw the original tree growing there as a standard a good many years ago. At the back of the stables, on an eastern aspect, there was a fan-trained tree which bore noble

fruit. It was a sight. The steward and gardener who lived at Eckinville when I visited it was Mr. McLauschan, a very worthy man, who could exhibit other subjects worth seeing besides the above Apple. He used to show the Ecklioville Seedling at the horticultural exhibitions at Belfast as a kitchen Apple. It carried all before it there. As a sauce Apple there is none to equal it. What an Apple for a market gardener! The only wonder is that it has not been planted in this country by tens of thousands. Plants can be had in the Irish nurseries, at least in those around Belfast.—W. HUTCHINSON, Gardener, *Lwyndu Court, Abergavenny.*

A YOUNG GARDENER'S GROWL.

Would you be so kind as to solve the following problem—How are young gardeners to learn to know fruits, their qualities, &c., when never allowed to taste? My own experience is, that you may look but not touch, and even if seen to be looking very minutely you are suspected of eating. Now, when fruit trees are not labelled, as in far too many cases they are not, it is a matter of some difficulty to learn to recognise apart a dozen of each of the best hardy fruits. Yet that is a small number towards the many varieties that are in cultivation. I am ashamed to own it, but I could not pick out a dozen varieties of all the hardy fruits by taste and appearance to be in any way certain about them, and yet I have been eight years at the trade. Certainly I have been chiefly out of the great fruit-growing districts. I have been under different gardeners, but only one ever offered to give me the slightest chance of learning the qualities of fruits, though often asked in a quiet way. It is not pleasant to be obliged to go about like a thief, as indeed one is, to get a taste of fruit which you are expected to know full particulars about. It is my belief that a third of the gardeners do not know one-quarter of the different fruits in cultivation, and apart from a list would be puzzled to name a collection to stock a garden, so as to give a proper and successful supply of fruit. What I say of hardy fruits is still more applicable to in-door fruits—Grapes, &c., as it is not in many places that there is anything like a complete collection. Your eyes will tell you the difference between a Black Hamburgh and a Muscat of Alex-

andria, but as for more you must wait till you have Vines under your own care, and then you may have a little opportunity of comparison. You may get over being caught taking a Plum or an Apple, but to take and nip a berry out of a bunch of Grapes, oh, dear! that would be enough to send your box to the nearest station, or at least to insure a lecture a yard long, and to have the vinery door locked.

Of course, where fruit is very scarce, it must be husbanded, and cannot be allowed to go for young gardeners to taste and compare, whether they are ignorant or not; but then so very little is needed with the help of Dr. Hogg's "Fruit Manual," that I cannot but think the lamentable ignorance of which I complain might be in a great measure remedied.

Then, again, in regard to new vegetables, it is the same. Young men in the bothy must not expect to taste new Peas and Potatoes. The difference between good and bad is of no moment to them now; when they are in a place of their own is time enough for them to begin to know. For the first year or two let them accept seedsmen's and nurserymen's opinions, and then after making some mistake or mistakes which nearly cost them their places, they will learn.—A YOUNG GARDENER.

P.S.—I hope you will excuse my growl, but it eases one's mind.

[There is, no doubt, some truth in what you say, but we have found that it is the easiest matter in the world to find or make a grievance. Some young gardeners, like young men in other trades and professions, find that there is no royal road to knowledge of any kind. Where young men enter on gardening as regular apprentices or improvers, and directly or indirectly pay so much for instruction, it is only fair that that instruction should be given according to the capabilities of the place. Where a labourer picks up knowledge as he can, and where all the gardener can receive from him is merely a regular and appointed amount of labour, he can hardly be expected to get regular instruction on all points from the gardener. Partly from getting labour better done, and partly from a large-hearted generosity, gardeners have been the most liberal of men in imparting whatever knowledge they may have possessed. In fact, there is no trade or profession where the peculiar knowledge of the trade is so much and so frequently made a matter of public property as in gardening.

Young men in gardens, in general, form no exception. It is seldom that a man anxious to get on, active, attentive, persevering, and obliging, would be debarred from any knowledge he solicited in a proper way. It is by such means that some of our best gardeners have risen to the top of the tree. Their good, upright, obliging conduct has made many friends for them wherever they went. But those who have had most to do with young gardeners will be the first to own that all of them do not possess these attractive qualities. Many professedly going to a garden for improvement, seem to care about little except to get over as easily as possible the day's labour; and if they feel so little interest themselves, it is not likely that the head gardener will repeatedly trouble himself to give the explanations and information that are received so carelessly. In general, then, where there is a great amount of ignorance, after a long period of probation, we would be more inclined to refer that ignorance to the carelessness of the man than to the proud indifference of the master. Of course, to every rule there are exceptions. Gardeners, and the best of them, are but men. On the whole, we think that many young gardeners hold unsound notions of what head gardeners are bound to do for them; and dwelling on this they remain ignorant of what they might know but for their proud indifference and carelessness.

Again, it would be well if young gardeners, and many of the public, too, would recollect that a head gardener is merely a servant, having charge of a certain amount of property, for which he is responsible to his employer. In most places there is a little latitude as to giving and receiving, but it is dangerous to act upon it without a clear understanding. Mere use is not sufficient if a man wishes to be above suspicion and all underhand gossipings. Many a gardener, to our knowledge, has gained the character of being hard, near, and close-fisted, when he was merely and simply honest and faithful to his trust. Gardeners are not unfrequently annoyed by employers being suspicious now as to what becomes of the effects of the garden. They thought they should have had a greater abundance of this, and a better supply of that. We hardly know how it would be if assistants were allowed to pick and taste at their will. Such suspicious proprietors might then think it best to get rid of their suspicions, and their garden too.

Under such circumstances gardeners have often a sad time. They know that things lessen and lessen, and cannot find out how. We fear it is not always the assistants that are to blame. Many think it no harm to pick when they have a chance, though having no right whatever. Visitors should use no more freedom in a garden than they would dare to do in a grocer's or haberdasher's shop. In many places a bad practice prevails of allowing visitors at the mansion to make themselves free of the garden. Under such circumstances the gardener is often at a loss how to get a good dessert, and if there are many assistants, a great temptation is presented to them to do as their betters do. We have seen a gentleman finger-and-thumb a score of Noblesse Peaches before he found one to his mind, and every one of those Peaches would retain the mark. In a few instances the employers may be anything but straightforward. We knew a gardener who was thus treated. The lady found fault day after day, that the fine wall fruit were disappearing. He was obliged to own it, but could not tell how. He had the borders fresh raked every morning, so that a single footstep should be seen; but still every day, without a single mark, few or more fruit were taken, and all his watching seemed useless. Having got half through his dinner one day he thought he would go out and look at the wall, and there was the proprietor using a long hooked stick to take the fruit off the wall, and trundling them across the border without leaving a mark. We have often fancied the looks exchanged. We have sometimes felt what a wrong it was that the character and the position of a gardener should be so much in the power of such an employer. What would some employers with just a spark of suspicion about them think, when they found out that the garden assistants were not merely workmen but tasters and consumers of their best fruit and vegetables?

The abuse in such matters has often led to the disuse of good customs, and thus the innocent have suffered for the guilty. Not so long ago a gardener was keeping carefully a fine lot of Cauliflower for a ten-days company, and had the half of them taken in one night. Another time the first gathering of a new Pea that the employer had heard about disappeared in the same way, and later still some kinds of new Potatoes, planted carefully for trial, had been all grubbed over with the fingers and a pointed stick, so that the objects in planting, in comparing samples and qualities, were completely frustrated. It would have been easy to have known where they went to. Even our correspondent would be inclined to own that this was both-tasting with a vengeance. Can anything of this kind be the reason why in many places now the young gardener assistants must live out in lodgings?

The picking and tasting and pocketing of fruit, is often more trying than even the loss of a few of the best vegetables. Often the best fruit intended to crown a dish are missing, and Mr. Nobody does all the mischief. A most liberal-hearted proprietor, on seeing a number of men gathering a nice quantity of small Strawberries from a quarter after all the best had been obtained for table and preserving, said he liked the principle, but if after such indulgence a man should be found helping himself except where allowed, he must be discharged there and at once. We know, too, many cases where kind indulgences have been altogether withdrawn because they were made the cloak to carry matters to an excess. Young gardeners and garden labourers may retort that old head gardeners might be equally guilty when young. That may be true, and yet not mend the matter. We should say, however, that gardens since then are doubled, or rather trebled in number, and proprietors now look more carefully for returns for the money expended.

We have been thus diffuse in going beyond our correspondent's complaints, because we wish to note the importance of these matters to all concerned.

1st, That the proprietors of gardens should not to any great extent exercise their undoubted right in picking and gathering fruit and other produce without the knowledge of the gardener.

2nd, That the same rule should apply to their visitors, and on similar conditions. This is especially necessary where a number of assistants are employed, as the frequent infraction of it would present to them great temptations, and we consider it wrong unnecessarily to put temptations in the way of any one. What would be thought of ladies and gentlemen going to a dairy, helping themselves to cream and butter, and pocketing eggs, and taking notice of nobody? Would it work well if pantry and larder were invaded and the contents freely abstracted, and yet a housekeeper, and cook, and butler be considered responsible? The same principle applies in a garden, when visitors take just what they like and disfigure what they

leave. You cannot make a gardener feel his responsibility whilst his employer and his visitors are constantly undermining that responsibility. The practice opens a wide doorway for all other petty pecculation, and seeing such a lady or gentleman at such things must be to him a sufficient reply if the gardener suspects a workman. Remember, we question not the right of proprietors to do as they like. Some time ago one of our amusing lady friends described the pleasure she had in culling and gathering garden produce, and how cross the old gardener looked. We would not deprive such of the pleasure, but they might have that and wreathe the old man's face with smiles by just telling him what they have done. If not, and if there are many assistants, they will suffer.

3rdly, So far as assistants are concerned, there is only one safe rule, that they pick and pull nothing from an Apple to a Grape without the cognisance and permission of the head gardener. We recollect when young thinking it very hard that a man who had lived a number of years in a place was told he could never more be trusted, because he was seen to gather and eat a few very early forced Strawberries. It was the principle that was involved; as the place was large, if everyone having access to the house had done the same there would have been small returns to the de-sert-table.

How, then, are young gardeners to know anything of the taste and qualities of fruit, and vegetables, and roots? Not as in the cases just referred to, by bringing their tastes in antagonism with the tastes and the rights of the proprietor; not by acting as if they thought that their main duty was to get as much as they could, instead of remembering that proprietors chiefly look on them and regard them from the utility point of view; not by acting as if their labour was a mere routine, and looking more at the clock than considering the causes and effects coming constantly before them; but by exhibiting industry, attention, and integrity, combined with an obliging deportment; and then, just as love begets love, nearly every gardener would be as anxious that his assistants should taste anything nice and new as he would be to taste it himself; and thus directed, a very small quantity will go a great way.

We may add here, that even where vegetables can be spared it is well that these should not be taken, but in small places be given by the gardener, and in larger places be collected for that purpose by the man who serves the kitchen, and who will then be responsible that no scarcity shall be felt there. From want of such simple rules, what was once a privilege to be cared for has been lost altogether.

On other parts of our correspondent's letter we do not enter, farther than to agree with him that the most of gardeners do not know the names, and far less the qualities of the fourth part of the fruit cultivated. Just as in the case of the Rose, it will often be better to cultivate a few of the best sorts than to have a number of them. It is hardly reasonable to expect, amid the many things required to be thought about every day by general gardeners, that they can know fruit like the late Robert Thompson or our present Dr. Hogg. It would perhaps be well if more made fruit one of their especial studies; and hence it is desirable that young men whose bent is chiefly in this direction should not waste their time in ordinary gentlemen's gardens, but should rather seek employment in nurseries and gardens where fruit is the principal thing. We have no fault with any man for making fruit the first object, but taking gentlemen's gardens as a whole, gardeners must think of vegetables first, fruit second, and flowers third. Everyone should gratify his taste, and there is no want of the means of doing so. That will be better than grumbling that he cannot get what he wants in a certain position.—F.]

LARGE CROP OF LAPSTONE POTATOES.

As we hear from time to time much about Potatoes, I have forwarded for your inspection a sample of Haigh's or Lapstone Kidney grown in old garden soil, enriched with hotbed manure, one-half being leaves. The ground was dug in winter, and a sprinkling of salt applied on the surface at planting time. On the 5th of April we trenched in the sets, allowing 28 inches between the rows and 12 inches from plant to plant, placing them about 4 inches deep. When the shoots appear above the surface the plants are kept free from weeds by the hoe being freely used among them, and as soon as they are well above the ground quicklime is applied pretty freely among them, and carefully forked-in. When the tops are about 6 or

8 inches high the plants are earthed-up and left to take care of themselves. On the 20th of September we lifted the crop in prime condition, and the yield was at the rate of 15 tons per acre. A sample is forwarded. The whole was free from disease, and of first-rate quality.—M. H., *Acklam Hall, Middlesbrough-on-Tees.*

[The sample sent to us was very fine and clean-skinned. Three weighed 2 lbs. all but a quarter of an ounce, and all the others were similarly sized. When boiled they were very floury, and of excellent flavour.—Eds.]

ALTON TOWERS,

THE SEAT OF THE EARL OF SHREWSBURY AND TALBOT,
ALTON, STAFFORDSHIRE.

VERY beautiful, very interesting, and certainly very singular are the flower gardens and pleasure grounds of Alton Towers. Different in character from almost all other English gardens, they may be said to consist of a number of curious designs, the rich and elaborate details of which present so much of novelty, that as one passes from scene to scene the feeling of freshness and interest is fully sustained throughout. The rich masses of foliage, in all the various shades of colour, on the deciduous timber trees, mingle with that of the more sombre-leaved Pinuses, clothing the steep hillsides of this "happy valley;" the various curious structures dispersed about, some quaint and fanciful in design, and others even more attractive by their elegant proportions and the commanding positions which they occupy; the numerous groups of statuary, the vases, sheets of water, cascades, terraces, glass domes glittering in the sun, and the flashing waters of the fountains—all appeal to us, exciting our interest and commanding our admiration. Nor does this feeling pass away when, leaving this "land of brightness," one passes onwards, either along walks where constantly-occurring bold, stern, rugged masses of rock protrude from overhanging banks in all that grandeur and dignity which is their peculiar property, or under living arcades formed by the arched boughs of trees, or along sloping banks, on which grow vast numbers of Rhododendrons, interspersed with wild Ferns—all tending to impart a romantic air of semi-wildness, totally different from the trim neatness of ordinary shrubberies, but still so well managed as to be quite free from any appearance of slovenliness, and, in fact, just sufficiently dressed to render the whole agreeable, while the graceful freedom of the wild woodland is retained in its fullest integrity.

What appears to me to be most wanted here is a greater expanse of turf among the shrubs, the groups of which are now so near to each other that they appear crowded and confused in many parts; more turf would impart breadth and dignity, and would relieve the monotony of these "wooded banks;" for even the most elegant exotic shrubs, when seen crowded together in such profusion, have a tame and unsatisfactory appearance.

Mr. Rabone, the gardener, whose kindness and courtesy I beg to acknowledge, is gradually effecting many improvements, such as opening up vistas through the woods, and cutting away many overgrown shrubs which obscure or confine the views; and from the admirable manner in which this is being done much valuable and important scenery has already been gained, and it is a matter for congratulation that this charming place is under the care of such an able manager.

The delightful walk from the Alton station, by which I went to the gardens, prepares one for the peculiar treat which is in store. Passing through the ornamental lodge-gate near the station we proceed up an ascent, so steep that numerous flights of steps are introduced at short distances from each other. This picturesque walk winding upwards among fine old Fir trees, the sides of the banks being richly clothed with Ferns, passes over the crest of the hill near a colossal mass of rock, which projects boldly from the summit of an eminence, and onwards past the grand entrance of the noble mansion, with its stern-looking embattled walls, calling to mind those by-gone days when the "stout Lord Talbot" rode to the wars with all his mighty following of knights, esquires, and men-at-arms.

The principal entrance to the gardens has fine, lofty iron gates, which open out of the park a short distance from the mansion. On the lawn, at the right of the entrance, are many fine Pinuses, among which I noticed a fine *Abies Douglasii*, a *Pinus Cembra*, and some good *Araucarias*. Near these stand

the cenotaph, *fig. 1*, designed from the choragic monument of Lysicrates, of Athens. The bust is that of Charles, sixteenth Earl of Shrewsbury, during whose life these gardens were principally formed. The circular stone at the base of the columns bears the pithy and appropriate legend, "He made the desert smile." The position of this appropriate memorial is well chosen; standing out in bold relief from the dark background of Pinus, it greets the visitor on entering the gardens, and thus the memory of one who did so much for the advancement of horticulture remains evergreen.

The walk from the entrance gates takes a bold sweep past the cenotaph, and on the semicircular space of turf opposite is a small but very picturesque flower garden. Its design is simple; it consists of a large circular bed, belted in front by a row of smaller circles, outside which is a broad ribbon border; next to this is a very broad band of *Cerastium tomentosum*, out of which springs a continuous line or chain of semicircles of that excellent dwarf *Lobelia Trentham Blue*. Next this comes an equally broad band of the dwarf orange scarlet *Pelargonium Harry Hieover*, a perfect sheet of bloom, better than I ever saw it before; then two rows of *Dactylis glomerata variegata*, next *Colens Verschaffelti*, then *Mrs. Pollock Pelargonium*, with *Amy Hogg* inside. This arrangement had a fine effect, and the appearance of the entire border was very satisfactory. The small circular beds contained dwarf bush *Roses*, and standard *Roses* springing out of a fine mass of *Asters* were the occupants of the large circle.

Behind this group is the enclosing wall which passes along from the entrance gates; the form of this wall is so singular as to be worthy of description. Instead of the usual flat surface, the top is built in the form of a number of raised curves, the graceful outline of which is in fine keeping with the irregular undulations of the pleasure grounds. Between each pair of these curves was a vase of suitable size containing a fine mass of scarlet *Pelargonium*, and growing from the ground upwards to the base of the vase was a *Cotoneaster microphylla*, kept pruned to the width of the square base, thus serving to convey the idea of a column on which the vase appeared to rest, altogether present-

ing a very novel and quaint appearance. Along one side of the pathway, running parallel to the

wall, was a broad ribbon border of about 100 yards long, and on the other side a number of detached beds, some of which contained a pretty mixture of *Purple King Verbena* and *Koniga variegata*. The ribbon border was very brilliant with a somewhat complicated mixture of various *Pelargonium*s, *Colens*, *Golden Pyrethrum*, blue *Lobelia*, and *Cerastium*. From here a walk leads directly to the upper terrace, past the grand conservatories, and then to a small circular Grecian temple standing invitingly at the extremity, and which forms an appropriate finish to this pleasant promenade.

Some fine views of the varied and picturesque scenery with which the gardens abound present themselves very agreeably from this point; one of the most striking is that of the Gothic temple, *fig. 2*, a lofty and elegant structure finely situated on the left side of the valley. Wildly beautiful, yet with an air of grace and refinement, is the aspect of the scene before us. Shrubs growing in all the wild

others kept pruned to a more formal outline; vases, statuary, and architectural embellishments, intermingled with bright masses of flowers, or with stately-foliaged tropical plants, and with fountains as varied in force and form as are their situations—some near lofty trees throwing their waters high in the air, the spray glistening in the sunshine, and blown per chance by the breeze among the surrounding branches, a cloud of sparkling mist; whilst others placed in some secluded nook only have a play of a few feet high, but which is quite as charming in its way as that of their more important neighbours—all these are spread around in such profusion as almost to bewilder one.

Let us now turn to the conservatory range, a singular structure, or rather series of structures, 300 feet in length, consisting of a grand central house with a smaller house on each side, and connected with it in one straight line by open corridors, *fig. 3*.

The central part of this striking and novel range has a lofty glass dome, with a smaller one on each side, supported by massive stone columns, the chief recommendation of which must have been their great strength. The sight of these huge

Fig. 1.—The Cenotaph.

Fig. 3.—The Conservatories.

supports reminded one strongly of the great improvements effected in buildings of this description since they were erected, for now by the use of iron columns, strength, lightness, and elegance are combined in such a manner as would astonish the builders of those bygone times. When Mr. Rabone took charge of this place the columns had no embellishment but that given by the hand of the architect. All this is now altered, and instead of appearing bare naked masses of stone, offending the eye, and from which it was impossible to escape in any part of the building, they have become pillars of floral beauty, and rank among its most attractive features. This pleasing change has been effected by covering the entire surface of the sides with mosa mixed with a little rough rich soil, the whole being fastened on with wire. In this covering was growing with great luxuriance a charming mixture of *Caladiums*, *Begonias*, *Ferns*, *Lycopods*, and *Tradescantia*, thus clothing the pillars from floor to roof in a simple but most effective manner. Two fine old Palms—one a variety of Date Palm, and the other a huge specimen of Fan Palm, the bole of which measured 5 feet in circumference—are growing under the large dome in a raised bed, the surface of which is covered with *Selaginella denticulata*, interspersed with a variety of *Caladiums* and *Begonias*, a plant of *Caladium magnificum* being particularly handsome.

Along the front of the corridors there is a uniform row of vases raised on pedestals and well filled with scarlet *Pelargoniums*, alternating with the columns supporting the roofs. Climbing plants cover the back wall of one corridor, and the other is entirely filled with a splendid plant of *Wistaria sinensis* trained on the wall and under the roof; the effect of this must be very fine when the plant is in bloom.

buildings contained a healthy collection of *Camellias* and other hardwooded greenhouse plants.

Fig. 2.—The Gothic Temple.

Not far from the conservatoria we come upon one of those pretty scenes of which there are so many here, complete in itself, and yet not unlike many other parts of the grounds in its most prominent features; it is just one of those bright spots on which the eye "loves to linger," and presenting itself suddenly, as it does, in all its brightness and beauty, one is constrained to turn aside to examine and admire. In the background, high up on the bank, stands a long square-shaped house filled with *Azaleas*; in front of this opposite the centre is a fountain having a curved line of tall handsome specimens of *Cypresses* on each side, close in front of which the bank has a perpendicular descent of a few feet faced by a wall. Immediately in front of the fountain, and resting on the top of the wall, is the recumbent figure of a lion, with the water from the fountain passing beneath it down a pretty cascade, with masses of bright flowers on each side, and with the whole abundantly interspersed with vases and statuary.

From this terrace a walk leads upwards to the screw fountain, a singular tapering column of stonework, deriving its name from the spiral hollows winding upwards on its surface; four flat stones encircle this at regular distances, and the water from its summit falls over the edges and passes away under the recumbent figure of an animal down a miniature cascade, which is overshadowed by the boughs of a fine scarlet-leaved Oak (*Quercus coccinea*). From this point the golden gate walk is visible; it is a short terrace walk, having a row of Irish Yews alternating with vases on each side, and there is a stone recess at the end. The bright colours

Fig. 4.—Alton Towers from the Gothic Tower.

of a ribbon border running parallel with the walk agreeably con-

trasted with the dark foliage of the Yews. Still ascending the left side of the valley, we come to the rock walk nearly two miles in length, deriving its name from the numerous jutting crags which project over and by the side of the walk at intervals throughout its length. Ferns grow among the masses of rock in great profusion. The abrupt rising of the hillside from this walk, the huge masses of rock and the overhanging boughs of trees, all tend to impart a wild, romantic air of grandeur.

Close to the entrance of this walk, on the top of an archway of rock, are some common Laurels and Yews, apparently growing out of the bare rock, but a closer inspection shows that before the soil in which they were first planted was all washed away by the rains, their roots had struck into the adjoining soil, and so the shrubs continued to flourish. Proceeding up a rude flight of steps, under this archway, along a walk with huge fragments of rock at its sides, up more steps, and we are at the door of the Gothic Temple, then up the spiral staircase leading to the top of this elegant building, whence we have extensive views across the valley to Cannock Chase and the Bagot Woods in the far distance. On the right bank of the valley the Swiss Cottage, an ornamental structure, nestles among the trees; and crowning the eminence near the entrance to the valley is the stately mansion of Alton Towers (*fig. 4*), with its embattled walls, its towers and turrets, its massive dignity impressing one all the more strongly from the commanding position which it occupies, and from the contrast which its huge proportions present to the numerous architectural features of the gardens visible from this point. — EDWARD LUCKHURST, *Old Lands, Buxted, Sussex.*

(To be continued.)

GARDENING IN ALGERIA.

FRUITS are not cultivated as much as might be the case were there improved facilities for exporting them to remunerative markets, though they form, as it is, a very large portion of the food of the people, both in a fresh and in a dried state. The Fig is as important an element in the food of the Kabyle as the Date in the dietary of the Arab. Olives are grown principally in the mountainous region extending between Morocco and Tunis, at from 1200 feet to 2500 feet above the sea; at a less elevation the fruit is not only inferior in quality, but in quantity. That portion of the Atlas range which runs through the province of Algiers produced last year 50,000 tons of the fruit; while during the first quarter of the year upwards of a million pounds of oil were shipped at the port of Algiers alone. The Locust, or Kbaroub tree, is destined to become one of the most important products of Algeria—perhaps for sugar, certainly for feeding cattle. What is very much wanted in this country is some remunerative arborescent culture; and nothing appears better adapted to the climate, or the requirements of the colony, than this valuable tree.

The time is not far distant when Algeria will become an important wine-producing country. It will furnish not only sufficient for its own consumption, but its wine will compete with the finer vintages of France and Spain. The chief faults requiring correction are:—1, The mixture of plants in vineyards; 2, The want of attention to the proper kinds of Vine for each climate; 3, Careless fabrication; 4, Want of proper cellarage; and 5, Precipitation in bottling. Before the French conquest, the natives only cultivated the Vine for the purpose of eating its fruit, and up to the present day they have not improved their defective system of cultivation. Even in European farms much yet remains to be done. The colonists of Algeria, coming as they do from nearly all the countries of Europe, are naturally inclined to introduce the mode of Vine-culture, and fabrication of the wine, with which they were familiar in their own country, without the slightest regard to its suitability to their altered circumstances; this defect is now understood, and will, consequently, be remedied. In the province of Algiers about 17,000 acres are under cultivation with Vines, though a great proportion of the surface is not in full bearing. This area produced during the past year about 1,350,000 imperial gallons of wine, generally strong and well flavoured. The cost of planting Vines varies from £4 to £9 10s. per acre and an annual charge of £2 5s. is required for its cultivation. This ought to produce in the plains about 350 gallons, and in the hills 200 gallons of wine, when the Vines have attained the full bearing age of five years. Raisins have not hitherto been made to any great extent; but attention is being turned in this direction, and one Spaniard has lately planted 100 acres of Vine, entirely for the sake of the dry fruit.

In the same province, in 1867, about 7390 acres were under cultivation as market gardens. Potatoes are one of the principal vegetables produced; the cultivation of these costs about £7 per acre, which area yields in dry soils from 4000 to 6000 lbs.; and in irrigable land from 16,000 to 24,000 lbs., in three successive crops. The production, however, is very uncertain, owing to disease and sirocco, and the seed has to be renewed from Europe every year. Potatoes sown in March, and gathered in June or July, sell at from 6s. 8d. to 8s. 4d. per cwt. Those planted in August and September usually fetch nearly double these sums. Sweet Potatoes produce from 6000 lbs. to 8000 lbs. in dry soil, and from 24,000 lbs. to 32,000 lbs. per acre, in irrigable land. Artichokes yield from 30,000 to 40,000 heads per acre, and sell for exportation to the Paris market at about 2s. per 100.—(*Food Journal.*)

WORK FOR THE WEEK.

KITCHEN GARDEN.

At this period let every inch of spare ground, if time permit, be trenched into sharp ridges. Spare ground to any considerable extent at this season is a sign of bad gardening. Let a good breadth of Cabbage plants be pricked out in rather poor soil; they will all be wanted in spring. Plant a good breadth of half-blanching stout *Endive* plants in every spare frame, also stout half-blanching Cos and Cabbage *Lettuces*. Pot for forcing in winter a stock of herbs, such as Sweet Marjoram, Mint, Sorrel, and Tarragon. Early-ripened *Sea kale* for forcing in dung beds or the Mushroom house may be trenched up with every root entire, and heeled in the compost-ground, in order to be drawn out successively as wanted. Gather *Tomatoes* as soon as they begin to colour, and complete their ripening in-doors in a good dry heat. Examine *Onions* in store.

FRUIT GARDEN.

Give occasional ventilation to the fruit room, shutting up as dry as possible. Gather all remaining Pears and Apples forthwith; if unripe they will receive no benefit out of doors after this period. Attend to the remarks on the removal of fruit trees in last week's calendar.

FLOWER GARDEN.

Choice flowers in the flower garden can no longer be depended on for affording a display; it is, therefore, desirable at this period to look over the masses and beds, and see if there be any plants of a tender character which it is desirable to secure for next year. Such may be potted with balls and wintered in the cold pits. Alterations may be proceeded with, also planting, turf-laying, edging, &c. The time is now arrived when all Tulip beds ought to be properly arranged for planting, so that the bulbs may be placed in the ground not later than the last week in October. Some means also should be adopted to shelter the bed or beds from heavy rain, as it is extremely prejudicial to the bulbs before they have begun to appear aboveground, and, in fact, excess of moisture ought at all times to be avoided. Attention ought likewise to be given to those bulbs of which the spikes have elongated. Aphis or green fly is apt to attack them, and should be carefully brushed off. In obtaining new varieties of Carnations and Picotees the best plan is to purchase them immediately; better plants will generally be obtained now than in the spring, and they will have time to establish themselves before winter. This is very necessary if they are to be kept in a state of health till next spring. Take care that the frames in which Auriculas are to be wintered have a proper pitch, and that all the glass is sound, so that the plants may not be subject to drip, which will be sure to ruin them. A free circulation of air should at all times be promoted, and when properly managed few flowers are more hardy than the Auricula. Pink and Pansy beds, I presume, are already planted. Some of the plants of both are occasionally "long on the leg;" such should be supported with small sticks, or they are apt to be broken over by the wind. After all that has been said about the spring or even midwinter planting of evergreens, I am persuaded that no period of the year can equal the autumn, say from the middle of October until the end of November. Much, however, depends upon the character of the soil as well as on the mode in which the operation is conducted. Some persons advocate puddle-planting, but on what principles I never could discover. Why not puddle-potting? Certainly it is better to puddle a large specimen than to totally neglect it in regard to moisture. The best practice is to open a hole much larger than the ball of earth or volume of roots about to be introduced, taking care not to make the hole any deeper in general than

the surface soil extends; then saturate the subsoil with water, and next thoroughly pulverise the soil intended for filling in round the root. After this is completed rake together a body of tree leaves, weeds, sticks, &c., and throw 3 or 4 inches (sometimes a foot), to the bottom of the hole to set the ball or roots on, putting little or no soil beneath the tree. The tree being carefully removed—not a fibre suffered to dry if possible during the operation—is placed on the leaves, and the process of filling up commences. Decayed vegetable matter is mixed with the soil; this is sometimes obtained on the spot by raking or paring the surface of the ground contiguous. The soil, being in a mellow state, is slightly trodden as the filling proceeds, and when filled level with the ball, or rather above it, the whole receives a thorough watering, using several cans of water at slight intervals. The next business, and a most important affair, is to thoroughly stake the tree to prevent wind-waving. When this is completed a thick mulching of half-rotten manure or leaves will finish the process. Such trees should have one thorough soaking of water in the early part of April, afterwards they may be safely left to themselves.

CONSERVATORY AND GREENHOUSE.

The climbers in the conservatory, at least some of the most rambling, will now want a good dressing where they obstruct the light in any material degree. Such as flower on the young wood, and which are now in a ripening state, or approaching a state of rest, may be pruned-in exceedingly closely. Such as the late-blooming Passifloras, the Combretums, Echites, Ipomoeas, Stephanotis, Thunbergias, Pergularias, and Mandevilla, which are still thriving, must be regulated with a more gentle hand, merely cutting off barren shoots, and drawing the remainder into somewhat closer festoons, in order to admit sunlight to the interior of the house. Some skill will be necessary in the mixed greenhouse, especially at this period; there will be so many candidates for admission that confusion and consequently failures will be inevitable, unless some things be discarded or removed to a cold pit or plant hospital. Better grow a few plants well than many badly. Now that the gems of summer are gone, or are on the eve of departure, let a strict eye be kept on those plants which, although of no botanical interest, are yet of great importance as cheering the mind amid the gloom of winter, when out of doors all appears a wreck. Let all flowering plants be kept near the glass in the lightest situation to be found, and, if possible, let those from warm climates enjoy bottom heat until they commence flowering, when they will do tolerably well without it. Let the stock of Pelargoniums have abundance of air, and sink gradually down into a sort of quiescent state, limiting the supply of water in proportion to the decrease of light. Preparations for hard weather should now be completed. All tender stock intended for protection under glass should be at once placed in winter quarters, plunging the pots, as before observed, in ashes or sawdust. A good supply of garden mats should be immediately provided, for although expensive they must be procured before frost. A good stock of new sawdust should be laid by in a dry shed to put round the stems of tender Roses or half-hardy plants. It should always be obtained as new and fresh as possible, but ought not to be applied to the plants for some time. A dry time should, if possible, be chosen, as a casing of such material immediately after heavy rains would probably be very prejudicial, for confined damp is in many cases a greater enemy than frost. Wooden shutters are very useful, whether to lay on as a temporary framework to exclude wet and the keenest of the frost, or to be employed instead of mats to cover pits and frames.—W. KEANE.

DOINGS OF THE LAST WEEK

The barometer having stood high without moving for the greater part of a fortnight, it fell considerably on the 7th and the 8th, and that with little apparent cause, as but a small quantity of rain has fallen, and there is no great appearance of much more coming, while there is but little wind to account for the change. It has induced us to look about, however, and put things in order.

KITCHEN GARDEN.

Before the rains came we took the opportunity to earth-up at once a lot more *Celery*, so as to come in about three weeks hence, using some burned refuse to go immediately round the stems of the plants. This, with the previous lime-dusting, would help to keep soft-skinned intruders away. Of course this dry rather acid material was quite cold before using it. A very small

quantity does for going round the *Celery*, if short lengths of old semicircular tin or zinc spouting are set round the plants. The earth is filled in in the usual way, using it well broken from the sides, and when sufficiently high the dry fine soil or ashes are put down inside the pipes, and when well pressed the pipes are drawn up, and the soil formed round the ashes. This takes more time than using the finely-pulverised earth alone, but it secures closer, and, therefore, better-looking *Celery*. Though not disapproving of large kinds, we still consider the Dwarf White Incomparable the best for small gardens, it takes up so little room, and requires so little earthing-up. A good plant 15 inches high will produce from 10 to 12 inches of blanched material for the table.

Apprehending rain, some time was devoted to the removal of Pea stakes where the crops were over, and of decayed leaves of vegetables which could not well be pointed-in. We forked the ground slightly among Cabbages, Coteworts, &c., so that the rain should have free entrance when it came, instead of caking the surface and running off. Planted also Lettuces and Cabbages to stand the winter, as the dry weather had deterred us from doing so before, and we scattered a little soot and charcoal dust among young Cauliflower plants, that the fly, so prevalent, should not molest them. It is rather singular how capricious the Cabbage fly is in its tastes. We have a nice piece of the Little Pixie Cabbage in one of our earth pits, where it succeeded bedding plants, and though the little heads are firm, not a fly appears on the foliage. Near to them, and in a similar position, is a bed of the earliest Coleworts heading nicely, but these have been attacked several times with clouds of fly. From our old Cabbage quarter, bristling with young Cabbages, we could not gather a dish without having to wash them well. If the rains do not help us, we shall give a cleaning to the quarter, and then syringe with soot or clear sewage water. The youngest Cabbage plants are the most infested; we have had to syringe and dust them repeatedly with fine soot, to save the little heart-point from the fly's ravages. On the 5th and 6th the air was quite darkened here about 4 P.M. with small flies. We have seen none on Savoys.

Mushrooms.—As we cannot use our Mushroom house, we have turned out the first piece we made in the open shed, and filled again with material for another bed. That piece gave us a fine lot of Mushrooms, but it is hard satisfying us, for we expected it to bear a few weeks longer. On examining it, however, the spawn seemed so run that we had little hopes of what it would do, and more especially as the litter that formed the chief part of the bed had heated itself rather dry. The second piece has been producing several weeks, and the third piece has been spawned and earthed-up. The first piece will now form the fourth succession in the shed. As it will have to produce after the cold weather sets in, we have made the bed deeper—about 18 inches deep at the back, and 14 inches deep in front. It is chiefly formed of litter, wetted sufficiently with sewage to make it heat and sweeten, but not to decay too much, and then surfaced with 2 inches of droppings. This, watched before spawning will, we have no doubt, do well. The roof of the shed, by keeping off wet and snow, renders the management of the bed much easier than if the bed had been a ridge out of doors. Such ridges must be well covered in winter, and in all our district straw will be very scarce this season.

This is a good time to make *Mushroom spawn*, where the cakes can be dried sufficiently before spawning them, but the process all through has several times been described fully. All who are contented with a small bed or two will find it by far the most economical way to obtain their spawn from a nurseryman who takes a pride in sending out a good article.

There is just as much care required to make a few bushels as in making hundreds or thousands of bushels, and it is here that the large spawn-maker can sell cheaper than the small maker. It is quite right to encourage work being done at home for the benefit of the neighbourhood; but provided home work is plentiful, there are many things connected with a garden which can be made more economically by machinery than by hand labour. For instance, we like to see garden sashes made in a carpenter's yard, with the use of the common tools; but no carpenter could compete in the matter of price with sashes where the most of the work was done by steam machinery. More will yet be done by acting on the division of labour principle. The great drawback is that machinery, as in our corn-thrashing machines, does at first lessen the amount of labour required without lessening the number of labourers to be employed.

FRUIT DEPARTMENT.

Proceeded with gathering fruit as it was fit, and now the chief proportion is housed in good order, though a number of the late Pears and Apples are out still. Where trees kept dwarf are rather luxuriant, and the fruit is gathered, a little *root-pruning* should be given without delay. The sooner it is done the more it will be likely to act, not only on the next season's growth, but also on the fertility of the tree. If the roots are cut late in autumn, or during the winter, the luxuriant growth will be arrested next summer, and greater fertility may be expected in the succeeding summer—that is, in 1872. But if the root-pruning is done in the end of September or the beginning of October, and the autumn should prove sunny, the pruning will tell somewhat on the productiveness of the tree the following season. Where there is little or no fruit, the root-pruning may be done earlier. We are not advocates for severe root-pruning at once, but would rather repeat the operation at different times. If the tree is not over-luxuriant, we would out a little on two sides opposite each other, and leave two sides untouched. If the trees are first planted on mounds, and are yearly mulched on the surface, when once in full bearing they will not need much root-pruning, and beyond summer-pruning not much pruning of any sort, as the fruit will almost exhaust the additional strength given by the mulching, and the roots will be encouraged to keep near the surface—a very different affair as regards the results from roots going deep. We should not forget that different principles ought to be brought into operation when we plant an Oak tree for timber and a fruit tree for fruit. When a fruit tree is treated like an Oak tree, a certain age and a certain degree of maturity must be arrived at before the tree produces fruit profusely.

Where *planting* is contemplated, any trouble in preparing the ground early and in fine dry weather will not be wasted. The more the ground is turned up and sweetened by exposure to the air before planting, the better will the trees thrive when transferred to their new quarters. Orchards in the old style, with even grass pastures beneath them, are very useful where large quantities of fruit are desirable. In such cases, and in all cases in general, it is less necessary to trench and prepare the whole ground than to prepare fair-sized stations for the trees to stand upon. Besides sweetening and exposing to the air the soil of these stations, it would be well to elevate them 6 to 12 inches above the general level, so that the tree should eventually have its bole rising out of a swelling mound. This elevation will not cause the tree to grow more freely at first, but it will insure better health and more fertility.

ORNAMENTAL DEPARTMENT.

The flower garden is still so good that we have been forced to mow, machine, and sweep up leaves, and to pick over the beds once more to remove faded blooms and some faded leaves brought on again by the continued dryness. The walks also were rolled after a shower to make them firm, smooth, and bright. The corridors, conservatory, and other places were gone over, and the tenderest plants removed. For glass cases in summer without heat, few things look better up to October from July than good plants of the better-coloured kinds of Calceas. Those removed now, if quite clean, will go at once to the rubbish heap, those infested with any insects to the burning heap, or where the coming cold will kill the whole. We have not room for wintering large plants, and therefore must keep some small ones and grow from cuttings in spring.

All such changing, and cleaning, and fresh furnishing should take place often. The gardener should try to go through his places with the eye of a stranger. It is amazing how apt we are to look upon a house as fresh arranged and fresh done up day after day, when it has been the same for weeks. The eye should, in fact, be more used at home to find out blemishes and imperfections than to be taken up with what is beautiful and interesting. In such cases it is often less a question of more or less work than simply seeing and acting on the sight. Hence a man with little or no more labour, and scarcely more time, will keep a house always presentable, and another man will have it always untidy, except immediately after one of these great out-clearings and fresh-furnishings. The first man, even when doing the necessary watering, will not pass an unsightly plant thoroughly exhausted, nor a plant with a few faded leaves, without removing it, nor will he pour water on every pot alike, just in the way of routine. The other never sees that a plant is faded, never sees the miserable wilted leaves, waters the decaying and the flourishing alike, and if let alone would never move a plant after he had once placed it on a shelf or platform. As a gardener must gain

his living by practising something of taste and order, looking out for untidiness ought to be an every-day and an every-hour operation. Some time ago we walked through a pretty little conservatory, communicating by wide folding doors with a richly-furnished drawing-room. The gardener was an able, intelligent man, but these qualities seemingly did not give him a sense of order or the faculty of observation. The fine stone curbs were slimy green, the stage had plenty of green, the pots were dirty, and though there were many blossoms, they were mingled with fading leaves, and the gardener seemed to see nothing of the discord between all this and the neatly-furnished drawing-room. We could not well venture farther than to move some of the slime from the stone curbs with a walking-stick in rather a contemplative earnest way, but our friend was not observant enough to take the hint. An advice worth having and valuing, we would say to our young readers, Beware of the habit of looking on plants, houses, and borders as just fresh arranged, fresh potted, fresh cared for, when days or even weeks have passed since the work was done. Look at such things as they are to-day without any reference to the past.

Struck Cuttings.—Anticipating rains we have overhauled lots of cuttings for the flower garden, that were thickly inserted in shallow wooden boxes and pots, setting them a little further apart, and removing every decayed and faded leaf. As stated formerly, we are obliged to take small cuttings and put them in thickly together, in order to be able to house enough of them under glass in winter. We find no fault, quite the reverse, with those who take large cuttings and give each a pot in winter. We must suit ourselves to circumstances. As these cuttings, rooting now, are so close together, there is the more reason that not a decayed leaf should rest upon them, as in dull heavy weather a few such leaves festering about the stems would be apt to gangrene and rot them, and, if free air could not be given, the very air about the plants would tend to produce decay. The cuttings thus treated had the surface soil sprinkled over with a mixture of fine sandy loam and charcoal dust, a good security alike for neatness and against damping and unhealthy vapours.

We shall make preparations for taking off our shrubby Calceolaria cuttings by the end of the month, and we find it is of importance giving the cuttings fresh soil, Herbaceous Calceolarias for pots we are potting and pricking-off now. They are most useful for corridors and cut flowers early in summer.

We intended to have alluded to different modes of treating old Geraniums in beds, but the matter has been alluded to, and further particulars can wait for another time.—R. F.

BANISHING FLIES.—The *Food Journal* states that in Belgium the hutchers use, with great success, laurel oil on the door-posts and window-frames for the purpose of keeping away flies. The emanation from minced laurel leaves is rapidly fatal to all small insects. These facts might point to gardeners and housekeepers how to exclude flies from structures where their presence is especially disagreeable.

TRADE CATALOGUE RECEIVED.

Lewis S. Woodthorpe, Munro Nurseries, Sible Hedingham, Essex.
—*Catalogue of Greenhouse and Herbaceous Plants, Fruit Trees, Ornamental Trees and Shrubs, &c.*

TO CORRESPONDENTS.

* * We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By doing so they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

PATENT (A Young Gardener).—You will ever repent of taking out a patent. Register your invention, and the probability is that you will never be repaid for that small expense.

PEARS FOR NORTH IRELAND (A. M. P.).—Doyenné d'Été, Jarzonelle-Williams's Bon Chrétien, Red Doyenné, Thompson's, and Knight's Monarch. The Noblest Peach ought to succeed with you.

PEACHES NOT RIPENING (C., Essex.).—What the name of the variety is we cannot tell from the unripe specimens, and no leaves—the glands on their stalks are guides in the non-enclosure of Peaches and Nectarines. We think the cause of the fruit falling, though well-coloured, and being tough in flesh, is want of moisture to the roots of the tree; water abundantly, and mulch the surface over the roots. Do the same every summer. The roots of the trees which have ripened their fruit may be nearer the surface, and are, probably, earlier-ripening varieties.

APPLES ON THE POMME DE PARADIS STOCK (J. Scott, Merriott Nursery).—The specimens of Apples from trees grafted on the above stock, are among the finest we have ever seen. The Brockworth Park Pear is a seedling. We are obliged by your note that the Apple called, on page 286, "Eckland Vale," should be "Ecklinville Seedling."

SEEDLING GERANIUM (C. Marsden).—The petals were totally shed; but if the truss had been perfect, we could have given no opinion of the value of the variety as a bedding plant, for that depends quite as much on the foliage and dwarf habit of the plants as on their flowers. There are hundreds having the same-coloured petals as those you enclosed.

BATSHELL SPROUTS (Amateur).—Do not cut out the head or leading shoot. In cutting the side shoots use the largest first.

VINES MILDEWED (St. Bridget).—The leaves and Grapes are destroyed by long-neglected mildew. As soon as you saw the "white powder" on the leaves you should have dusted them with flowers of sulphur. Pick off all the Grapes, dust the leaves thoroughly with flowers of sulphur, paint the stems and branches with a creamy mixture of clay, flowers of sulphur, and water, and sprinkle over the surface of the borders, &c., with flowers of sulphur. As the leaves fall burn them. Next year use flowers of sulphur as soon as the white powder appears, and until it ceases to appear continue applying the sulphur. The white powder is a parasitical fungus, Oidium Tuckeri.

CHARGE FOR PAINTING (Notice).—These are matters we prefer to leave to tradesmen and contractors. It is impossible to tell you what should be allowed for the stopping and scraping old work before painting. If it is in a very bad state the work would have to be allowed for; if not, it would come in with the first coat of paint. As you speak of stone colour and oil, we presume you mean white lead merely toned down a little. For three coats of such paint on a fair smooth surface, about 5d. per square yard would be a just price. In some cases the cost would be more, and in others less. The coats we would value as three, two, one, the first coat always taking up more material. Windows would be less or more according to the number of the bars and the size of the glass. The more cross-bars the more expense. For common-sized squares, the windows should cost quite as much as the plain work. In large squares, and where, as in hothouse roofs, there are no cross-bars, the price should be less. We merely from calculation say what the work may be done for; we cannot tell you where it may be done, but this will be all. All painting is measured by the square foot or yard. All semicircles and angles measure as squares—that is, the greatest length and the greatest breadth. Your windows would be measured just like a wall—by the greatest height and the greatest breadth; thus, a circular window would be measured by squaring the diameter. We know that new garden sashes painted four times cost about 1d. per foot—that is, 9d. per yard, and that would be 4d. per yard for the outside. If you paint your windows inside as well as outside the measurement will be doubled.

MUSHROOMS IN HOUSES MAGGOTY IN SUMMER (A Soldier).—This is a very common occurrence in hot summers where coolness cannot be sufficiently secured. Airiness without draught, and coolness, are next to indispensable to good Mushrooms in summer. Hence the advantage of cellars for summer growth. We have been frequently troubled with maggots, though some summers we have escaped altogether. Much may be done with double or thick walls and a double roof; or, if not, thatch, whitening it after May to keep the heat out. Much also may be done by syringing walls and floors, but it is difficult to grow good Mushrooms in houses easily heated by the sun. We prefer an open shed, or the open air under the shade of trees, but a place underground is best. See what was said at page 261.

WINTERING SCARLET GERANIUMS (Subscriber).—Such fine large plants taken up out of the beds would do best if potted individually, but they will do very well if packed thickly in large pots, or shallow boxes quite as thickly as they will go together, so as to resemble a faggot. If you do not wish your plants to be large you may cut away the shoots 6 inches or so above the collar of the plant; but if you wish to have rather large plants at planting time next year, the best plan is to take them up carefully, cut off all the soft ends of the shoots close to a joint, remove every leaf, dip the cut tops in a dry powder of lime and charcoal to stop bleeding, trim the roots a little, and then pack them as thickly as they will go in rather sandy loam in boxes, &c. We have crammed more than a dozen fine plants in a 10-inch pot. When nicely packed, and as firm as may be, water, so as to moisten the roots and soil, and allow them to stand until the surface soil is dry; then cover with an inch or so of dry soil, and as you cannot give them a place on the greenhouse stage, any dry place will suit them where they can be secure from damp, drip, and frost. They will do anywhere—under the stage of the greenhouse, in spare rooms where there is a little light, in dry cellars, in garrets, or in haylofts, where the frost cannot reach them. In open haylofts we have known them do well where loose hay was thrown over them in frosty weather. The more succulent the stems the more easily are they injured by frost. The roots are more apt to suffer from damp than frost. Hence little boxes of a convenient size, say from 4 to 6 inches deep, are better for packing in than large pots. When so kept it is best not to excite them in winter, but rather let them remain dormant as respects their stems, being content to see them putting forth little leaves after March. When these leaves become larger than a shilling the plants will want thinning out. To make fine plants from such Geraniums, take them up as above, remove all the large leaves, but leave the points untouched. These must have light and better treatment.

HOUSE FOR VARIOUS PLANTS (J. C.).—We think the Tropæolum is doing as well as you can expect at the back of a house with Vines on the roof; and even if there were none, Tropæolums are apt to lose their lower leaves. The *Lonicera* requires plenty of light and air. The back wall of a vinery, such as yours seems to be, is very unsuitable for it and similar

plants. It is better suited for Camellias and Orange trees. All the two plants you name require, seems to be light and air. Ferns, you say, thrive well in the house, that is proof there is moisture and shade; but as some are stove kinds, your only chance of keeping them is to preserve the soil as dry as you can without causing the fronds to flag. Unless the house is very high and wide a flow and return hot-water pipe will be sufficient to keep out frost. We do not understand you as to the trellis-work preventing air passing through. If air cannot pass through, it is not trellis-work at all, but some close material. If the front openings are too large why open them so much? Top air is preferable to so much side or front ventilation. *Canna indica* dies down every winter. It ought now to be kept short of water, and when the leaves turn yellow cut them off, and keep the roots dry in winter and secure from frost. In February repot them, and place them in a hotbed, and when the shoots are a few inches long remove the plants to a light airy part of the house.

PRUNING LAURELS (Tereus).—The most suitable time to prune Laurels, especially when they require much cutting-back, is at the end of March or beginning of April, or when they are beginning to grow; but any irregularities of growth may be removed from August to October. For transplanting Laurels no time is so suitable as the present, for the soil, owing to the late rains, will be moist; if as dry as it was a short time ago planting must be deferred until it is thoroughly moistened. October and November, February and the beginning of March, are good times to plant Laurels.

REMOVING SULPHUR FROM RIPPED GRAPES (T. V.).—Blow off the sulphur by means of a pair of bellows. If it fail, which we have not found, syringe the Grapes a few hours before wanted, to allow of their becoming dry before disking up. Only those required for present use ought to be syringed, for if those on the Vines are syringed the berries will crack, spot, or decay.

PRIMULAS AND CINERARIAS NOT THRIVING (Duncanensis).—We think the Primulas are unhealthy because you syringe them; discontinue it. Do not water until the soil becomes dry, but before the leaves flag; then give a good supply, and do not water again until another watering is required. We cannot account for the Cinerarias drooping. They should be watered as required, and syringed occasionally. Perhaps the plants are infested with thrips or aphides, for which fumigation with tobacco is the remedy. In the position you name they ought to do well.

SOWING SEEDS (Mary).—It is rather late for sowing *Echeveria metallica* and *Pyrethrum* seeds in a hotbed, but you may yet do so if very careful in watering, in giving the plants air, and in keeping them near the glass. Stocks, Delphiniums, Schizanthus, Centaurea, Silene, and Saponaria you may sow now in pots, and keep the seedlings near the glass in a greenhouse. If you keep them from becoming drawn all will be well, but we should have had more confidence of success if you had sown three weeks or a month earlier.

RANUNCULUS PLANTING (Idem).—The sloping border which has been occupied with Geraniums will answer for Ranunculuses. Give a good dressing of rotten manure, dig the ground deeply, and make it fine. Plant in November as soon as the ground can be prepared, and in December mulch with about half an inch of partially-decayed leaves. If the weather be dry in April and May water copiously.

PEA HURDLES (M. S.).—We have used them for years, and find them answer well.

MANURE AND POTATOES REQUIRED TO PLANT AN ACRE OF GROUND (Idem).—Twelve good loads of farmyard manure are a good manuring for an acre of ground, and to plant an acre, ten bushels of ordinary-sized sets are needed. The rows should be 2 feet 6 inches apart, and half that for the sets in the lines.

REPLANTING PANHIES IN THE SAME BED (Idem).—It is not good to replant them in a bed in which they have grown previously. Fresh soil is best. If you manure well, and dig deeply, they may do well.

GRAPES COLMAN GRAPE (Bertram).—This is a very late variety. Bunches large; berries very large, round, jet black, and very beautiful; skin very thick; flesh very coarse, and coarsely flavoured; constitution very robust. It is a Grape which will hang well, and has a splendid appearance, but if without any other recommendation.

MELON DE NAMUR PEAR (H. H.).—Thanks for the example. We must say it seems to us very closely allied to Doyenné Blanc. It is of the same form and colour, the same in flesh, and almost in flavour. The eye, however, is different, being open, and the stalk is longer and more slender. It is a good Pear, but inferior to some others of the same season.

SELECT STOVE PLANTS (Store).—For foliage or variegation: *Alocasia metallica*, *Areca Verschoffelti*, *Calamus asperimus*, *Cocos Weddelliana*, *Croton interruptum*, variegatum, *longifolium*, *Dieffenbachia Pearcei*, *D. Weirii*, *Maranta illustris*, *M. roseo-picta*, *M. Veitchii*, *Pandanus javanicus*, variegatus, *Sanchezia nobilis variegata*, *Thrinax elegans*, and *Verschaffelia splendens*. Flowering: *Allamanda nobilis*, *A. grandiflora*, *Anthurium Scherzerianum*, *Bougainvillea glabra*, *Clorodendron Thomsense*, *Dipladenia amabilis*, *D. crassinoda magnifica*, *D. splendens*, *Gardenia florida intermedia*, *Hoya bella*, *H. imperialis*, *Ixora acuminata*, *I. floribunda*, *I. coccinea superba*, *Medinilla magnifica*, *Rondeletia speciosa major*, *Stephanotis floribunda*, and *Thyreacanthus rutilans*. *Cyathophyllum magnificum* requires in winter a temperature of 60° at night, and from 65 to 70° by day. The soil should be kept as dry as it can be without causing the leaves to flag.

WINTERING GERANIUMS (N. C. H.).—Having no greenhouse, the best place you can give the old plants in the boxes will be the cellar, all or the greater part of the leaves being stripped off. They will not require any water from now until March, when they should be placed in the light, and, if possible, in a frame on a slight hotbed, watering carefully at first, and increasing the supply with the growth. When in the cellar look them over occasionally, removing all decayed leaves. The cuttings would be best in a place where they could have light. A room will answer very well; keep them dry, but if the leaves flag a little water should be given. The old plants will do in the dark cellar.

APRICOT TREES UNFRUITFUL (A Subscriber).—Your trees must be in a poor state, and we think, from the great number of suckers that are formed, that the soil is wholly unsuitable. Clay and bog are not desirable for Apricots. We should take the trees up, cutting all the roots more distant from the stem than 3 feet, and removing the soil, but preserving

all the fibres; you will thus be enabled to cut off the suckers close to their point of origin. Use a compost of fibrous loam, adding one-sixth of old lime rubbish or, what is better, chalk in pieces from the size of a walnut to that of a hen's egg, and do not cover the fibres with more than 3 inches of soil. Mulch over the roots with about 3 inches of littersy manure. The aspect is suitable.

DECIDUOUS TREES FOR A LAWN AND SHRUBBERY (W. G. W.).—Of trees proper, or those which attain 20 feet in height or more, we advise *Acer platanoides colchicum rubrum*, *A. platanoides laciniatum*, *A. rubrum*, *A. pseudo-platanus* (Sycamore) and its variegated forms—viz., *albomarginatum* and *foliis purpureis*; *Aesculus hippocastanum*, and the pink and scarlet-flowering varieties—if you have a wet spot, *Alnus glutinosa laciniata* will suit; *Betula alba* and *pendula*, *Castanea vesca*, and var. *aureo-variegata*, *Cerasus Padus*, *Fagus sylvatica* and var. *asplenifolia*, *purpurea*, and *pendula*; *Fraxinus excelsior pendula*, *Juglans regia laciniata*, *Liriodendron tulipifera*, *Magnolia acuminata*, *M. conspicua*, *M. purpurea*, *Morus alba*, *M. nigra*, *Ornus europæus*, *Populus argentea* for a wet place, *Pyrus communis* and var. *pendula*, *præcox*, and *Bottle-tree*, *P. Malus prunifolia*, *Quercus Robur asplenifolia*, *Robinia pseudo-acacia*, *Salix aurita adnata*, *Salix americana pendula*, *S. babylonica* Kilmarlock Weeping, *Tilia europæa*, *T. laciniata*, *T. sanguinea*, *Ulmus campestris asplenifolia*, *U. fastigiata*, *U. montana crispata*, and the *Campdenowa Elm*.

GERANIUM CONFEDERATE (*One in Suspense*).—Confederate was sent out by Mr. Morse, of Dursley, and raised, we believe, by Mr. Gheny; it is intermediate between Tom Thumb and Little David, and no doubt a seedling of the former, a good bloomer, but not sufficiently distinct to make it worth while to keep it as a separate sort, but it may be used with Tom Thumb.

ROSE'S LEAVES ALMOST BLACK (J. Salford).—The Rose leaf enclosed seemed to us to be suffering from the effects of some deleterious chemical; and we should fancy from its appearance, that during the hot and dry weather at the end of September the leaves of your trees have suffered from the smoke of some chemical works. The wind having been very constant for some time, and the atmosphere very still, any Rose trees situated in the line of the smoke of gas works, agricultural manure or dye works, would be more liable to injury than usual. Although the leaf sent was eaten in places by insects, yet the general injury to the leaf does not seem to arise from insects. We should be glad to learn more, of the position of the trees. Constant syringing with clean soft water, and an occasional application of a little soft soap, will be the most likely remedy.

HEATING A SMALL GREENHOUSE (Grimshy).—A small moveable iron stove, with a flat top to receive an evaporating basin, would be the best for your small house. You should have the stove lined with fire brick, or large enough to have the fire-place in the centre, and a couple of inches or so from the outside iron. You will thus have plenty of heat without the outsides of the stove becoming dangerously hot. You may, as you propose, burn charcoal in such a stove, or, more cheaply, use coke or fine cinders; but in neither case will you succeed unless you have a pipe from the stove going right out of the house. The simplest plan is to have a plate-iron pipe going through the glass roof, a square of the iron with a suitable hole for the pipe taking the place of a square of glass taken out. Regulate draught and consumption of fuel by the asphit door.

MELON AND CUCUMBER HOUSE (*A Lover of Our Journal*).—The plan sketched out will do for Cucumbers and Melons late in spring, in summer, and in autumn; but for winter and early spring use the piping would not be sufficient. In the latter case we would advise having 4-inch pipes in the tank instead of 3-inch pipes, and making the tanks 5 inches deep. The position of the top pipes will do very well, but we would have two instead of one on each side of the house, having one on the side next the pathway. There, too, we would have 4-inch pipes instead of 3, as such a span house will radiate a great deal of heat if no covering is used for the glass. We would, in the case of the tanks as well as the top heat, have the flow pipes next the outside walls. It would be well to have upright open-ended pipes from the tank to admit vapour into the house. Without that you would require evaporating pans on the top flow pipes. The pitch of the roof would answer very well. Were we erecting such a house we would have a double ridge-board, with 8 inches between for a ventilator, and a hood of two boards—A placed over, to let air in and keep out wet.

NAMES OF FRUITS (B. M.).—NONOSUCH. (J. A. Woodlands).—Pears: 1a, Fondante d'Autonne; 2b, Doyenne du Comice; 3c, Winter Nelis; 4, Urbaniste. Apples: 5c, Lord Suffield; 6f, King of the Pippins; 7g, Fearn's Pippin. (F. A. F.).—Apple: Emperor Alexander. (W. B., North Wales).—Apples: 1, Mauks Codlin; 2, Fearn's Pippin; 3, 4, King of the Pippins; 11, Beauty of Kent. Pears: 13, Duc d'Orleans; 14, 16, Beurre Diel; 17, Fondante d'Autonne; 20, Bon Chretien d'Hiver. We must decline to name so many at one time. (William Mills).—The Pear is at present unknown to us. It may probably be Gansel's Bergamot. (*A Subscriber*).—Pear: 21, Marie Louise. Apples: 8, Margil; 11, Downton Pippin; 15, Kerry Pippin; 26, Waltham Abbey Seedling; 78, Court of Wick. (Parcel received from Crediton without Name).—Apples: 1, Cox's Orange Pippin; 2, Early Nonpareil. Pears: 1, Beurre de Rance; 2, Urbaniste; 3, Marie Louise; 5, Glon Moreau; 6, Nutmeg; 7, Van Mons Léon le Clerc; 9, Winter Nelis; 11, Fondante d'Autonne. (Hyke Cross).—Pears: 1, Beurre de Rance; 2, Passo Colmar; 3, Vicar of Winkfield; 4, Doyenne du Comice; 5, Beurre Diel; 6, 7, Knight's Monarch. Apples: 3, Prague; 6, Blenheim Orange. We decline to name more of them. (J. B., West Lodge).—Your fruits, we regret to state, got mixed up with others, so that we entirely lost trace of them. (S. L.).—1, Trumpington; 2, Mauks Codlin. We cannot tell. (Bruno).—Your Apples are unknown. The present is a good time for the removal. (C. W. C.).—2, Bergamotte Cadette; 3, Beurre de Rance; 4, Ord's Apple; 5, Colham. (E. B. K. L.).—1, Beurre Diel; 2, 3, Glon Moreau; 4, Napoleon; 6, Deux Sours. The prickly plant is *Datura Stramonium*. (K. Jenner).—1, Messire Jean; 2, Uvedale's St. Germain; 3, Not known; 4, Grosse Caléasse. (M. H., Acklam Hall).—The Pear is Suffolk Thors. No. 2 Apple, Scarlet Nonpareil; the other two Apples we do not recognise. (M.).—Red Autumn Calville. (J. H., Elmhurst).—1, Grosse Caléasse; 2, Conseiller de la Cour; 5, Red Doyenne; 6, Beurre de Capiaumont; 7, Kentish Filbasket; 8, Mère du Ménage; 9, Stamford Pippin; 11, Golden Russet; 12, Lewis's Incomparable. (J. L. C.).—2, Court-pendé-plat; 3, Claygate Pearmain; 5, King of

the Pippins; 6, Golden Russet; 7, Robinson's Pippin; 8, Yellow Ingestrie; 10, Adam's Pearmain; 13, White Nonpareil; 14, Pitmaston Nonpareil; 15, White Melrose. (Rev. Mr. McCalmont).—The Pear is Hampden's Bergamot, and the Apple we cannot identify, as the specimens are evidently small and uncharacteristic. (E. U., Lyscay).—1, Golden Noble; 2, Drap d'Or; 3, Early Nonpareil; 5, Yorkshire Greening; 6, Augustus Pearmain; 7, Sturmer Pippin; 8, Maiden's Blush; 11, Vicar of Winkfield; 12, Lewis; 13, Napoleon. (W. G.).—Your Grapes are correctly named, with the exception of Muscat of Alexandria, which is White Frontignan; and we have great misgivings about Royal Muscadine, which we think no amount of shade would have altered to the appearance of the Grape you sent us. (W. J. H.).—We are sorry we cannot identify the Pear.

NAMES OF PLANTS (*A Halstead Subscriber*).—You must send fresh specimens, each numbered, or we cannot apply the names. (G. M.).—Ruscus hypoglossum, Double-leaved Encher's Broom. (*A Very Old Subscriber*).—1, *Bonaria edulis*, often called *Alstromeria edulis*; 2, *Acacia decipiens* var. *premorsis*. (H. A.).—Your plant sent in bloom is *Clerodendron fruticosum*, a native of North China. We certainly should not recommend you to allow your Ivy, however ornamental it may be, to entwine itself round the Laburnum. Try to find a less objectionable situation for it. (*A Constant Reader*).—The Crategus sent proved to be *C. coccinea*.

POULTRY, BEE, AND PIGEON CHRONICLE.

POULTRY SHOW REFORMS.

THERE was an article in "our Journal" a short time since on the management of Canary shows. May I be allowed to offer a suggestion or two as to Poultry shows? First, as to catalogues. Now, I take it for granted that every exhibitor at a show, at all events every exhibitor whose entries amount to, say, 10s., is entitled to a ticket of admission; but at every show it happens that there are many exhibitors who cannot be present themselves, but are naturally anxious to learn as soon as possible what success has attended their efforts; and I think in such cases they should be entitled, on returning the admission-ticket to the Secretary before a certain date, to have a catalogue and a list of the prize-winners forwarded to them free by the first post after the award of the prizes. It need not give the Secretary much trouble. Let him procure a number of the halfpenny stamped wrappers beforehand, let him write the addresses on them as the returned tickets come in, let him file them, and when the great day arrives it will not take him long to wrap up the catalogues in them and consign them to the post. It is very annoying to have to wait day after day "in dread suspense," and after all, as has several times happened to me, receive no prize list until it has already been announced in a public journal.

And now as to these same reports, dear Mr. Editor, could you not make them rather fuller and more detailed? In the summer I have often noticed that the poultry portion of the Journal is compressed into a very small compass. Now, I have no objection to that. I am very fond of my flowers, and I look with interest for the reports (and very well written they are) of the great flower shows, new roses, and so on. But in the autumn and winter they are gone by, the poultry shows come on thick, and I taru with equal, or, perhaps, greater interest to the doings in the poultry world. Now, could you not at this time of year take a leaf out of the gardening book and push it back for a page or two? I am sure the value of "our Journal," in a poultry-fancier's eyes, would be greatly increased if we could have more detailed accounts of the poultry exhibited. I do not mean such an account as that of "Wiltshire Rector's" journey to Stroud, in which the journey occupies about ninety lines, the fowls thirty, and the Pigeons eight. (No offence to our good friend, whose letters are always amusing, and whose acquaintance I hope some day to make.) What we want is a more detailed account of the birds and their points. We are not much wiser after reading that "Cochins were good, Game moderate, and Hamburgs poor." We want to know what were the good points of the winners, what the failings of the losers.

I am told that the reports are mostly written by the judges themselves, and if that is so, who is so fit to criticise the different specimens? What disputes would be saved! Breeders would know what points to try for; for there is a fashion in the points of poultry as in most other things. Vulture-hook controversies would not have occupied so much space. Dragon-breeders would know what to do. Fantail-fanciers would not be in doubt whether head or tail was to be the first thing to see to. Turbit-breeders would know whether the turn-crown or the point-head was to be considered "the thing," and so on. If the critiques gave rise to some discussion, so much the better. The reporters, after giving their *ipse dixit*, need take no further part in it, unless they wished.

One word as to pens. I was very pleased at the late Middleton Show to see the large, roomy, well-lighted pens; all quite patterns except those in which the Fantails were boxed-up. They were sadly too small. The poor inmates could scarcely turn round, and as to spreading their tails, that was out of the question.

I think it is one of the first duties of a committee to see that the birds entrusted to their care are made as comfortable in their confinement as possible. I have a vivid recollection of the Variety Duck class at the Hanley Show last winter. The poor unfortunates were not penned at all. They were just set out in a row on the floor of a desolate building, in the hamper in which they had travelled, the lids being set open, and a bit of wire netting fastened on instead. I remember particularly a wretched little Mandarin drake, shut up in a tiny hamper in which he could barely move. There he would be, say, one day on his journey, two days at the Show, and another on his return. Fancy the condition of his beautiful fan feathers after such an imprisonment! Secretaries know beforehand exactly the number of entries, and they ought to provide sufficient and proper pens for all.—SNOOPSHIRE RECTOR.

BREEDING FOR POINTS.

I FIND nearly all fanciers admit it is a great deal easier to breed fine fowls or other poultry lacking in one or two important points, than to breed perfect birds. Hence, one would be very glad to regard his Brahma cock which has fine white neck-buckle as right, because he is so very large and fine; another does not object to ignoring the muff in Houdans; another asks: Are not Aylesburys just as good if their bills are not quite so "pink as a lady's nail?" This will not do. We must not neglect a point because it is hard to breed. If we throw out a point it must be because the best birds, as such, with great uniformity do not possess it, or exhibit it in an unmarked manner.

Within certain bounds, no man can tell what limit to assign to man's power to breed striking peculiarities in birds or animals. Any careful breeder may, if he pleases, establish a breed of fowls entirely distinct from any other known variety. We have half a dozen breeds of some local fame now, but of what use are they? There is no need of multiplying varieties. We should rather strive to reduce the number. For example: The Leghorns are a useful breed, they fill a peculiar place, they are not properly a fancier's breed like the Hamburgs, they lay large eggs, are very tough and hardy, belong to the class of non-sitters, though they not unfrequently sit and make good mothers, yet why should we suffer Leghorns to carry such a variety of points in which variation is allowable? We can find in the same flock single and rose-combed birds; white, pink, and yellow legs; white, bluish-white, cream-coloured, and red earlobes. Why then should we not taboo pink and white legs altogether? If rose-combs ought to be retained, let the varieties be kept distinct. Cream-coloured earlobes usually go with yellow legs.—(Poultry Bulletin.)

ANTWERP PIGEONS.

I HAVE read with much interest a paragraph in your last number headed "Prizes for Antwerp Pigeons." For many years I have been a Pigeon and fowl fancier, and in my time have had Dragons come from all distances, but always preferred Antwerps, considering that they were better breeders, and quite as much, if not more, attached to their homes.

I recollect, thirty years back, the late Sir John Sebright, Bart., who had one of the best assortments of Pigeons, told me he had had given to him two pairs of Antwerps, and after keeping them confined for twelve months, when he had bred sufficient young ones, he allowed them to fly. The old birds, however, even after that lapse of time, returned to their first home, but were sent back to Beechwood Park a few days afterwards, where, I presume, they were incarcerated for a further period, but, I hope, not with hard labour.—G. W. BURROW, 33, Richmond Road, Dalston, N.

THE IPSWICH POULTRY SHOW.—We have just been favoured by a letter from the Honorary Secretary of the Ipswich Show, showing the intention on the part of the local committee to hold the annual meeting on the 17th and 18th of November

next; and also it is stated, that by means of many additional silver cups and considerably increased money prizes, it is intended to give great inducements to exhibitors. Full particulars will be issued in the course of a few days in the printed prize schedule of the Society, and also by advertisements in the public newspapers. Knowing the excellent arrangements of the former Ipswich shows, and the special care taken of the poultry sent for competition, we are glad to find the announcement of a contemporary that this show was defunct is without foundation, and hope all success may be ensured to the coming show.

LONG SUTTON POULTRY SHOW.

For this annually-increasing Poultry Show a shed entirely of wood, 100 yards in length by 20 yards in breadth, was erected. This arrangement, combined with the Messrs. Turners' show pens, placed the Exhibition held on the 5th and 6th inst. in a very favourable position for public view. It is a matter of congratulation that so important an increase has taken place in the competition at this local Show during the few years it has been instituted. As Long Sutton is not one of the easiest of places to transmit specimens to, this result may be ascribed to the public confidence inspired by the careful attention given by the managing Committee. The weather was very favourable, and the attendance of visitors resulted in an unusual amount being taken for admissions.

The *Cochins* were extraordinarily good, more particularly the hen and pullets; Lady Gwydyr, Mr. Lingwood, and Mr. Dutton showing pens in first-class condition. The *Grey Dorkings* were not so good as on previous occasions. *Dark Brahms* were very strong and capital classes. Never need a better display of *Hamburgs* be brought together, and certainly an improved prize schedule for these breeds is deserved. Though so limited in numbers, very excellent *Game fowls* were shown, the Brown Reds of Mr. Laming being the cup-winner. The Black Red Game *Bantams* were not so perfect as at most previous meetings, but the Brown Red and the Red Pale Bantams were decidedly improved. Good Sebright and Pekin Bantams were shown in one general class.

Pigeons have rarely formed better classes at any exhibition in the locality, the Barbs and Carriers especially. Almonds, Pouters, and Toy Pigeons were well represented. *Rabbits* were numerous and good.

Mr. Hewitt judged the poultry, Mr. Tegetmeier the Pigeons, and Mr. Hutton the Rabbits.

THE Pigeons were the best collection we have ever seen since the Crystal Palace Show. In old Carriers Mr. Fulton won the cup and all the prizes, save one by Mr. Massey, who also showed an unnoticed couple of Black hens, which we think deserved a better fate. In young Carriers between twenty and thirty kinds competed—a sufficient proof, if any were wanting, that prizes for young Pigeons as well as old will before long be the rule and not the exception. The first prize went to a Dun from Mr. Massey, the second to Mr. Holt for a good Black. They were a very good lot, and gave the Judge some trouble. In Pouters Mr. Fulton again won all the prizes, save one by Mr. Harvey. For Almonds the cup went to Mr. P. H. Jones, who had a pair in good feather, but a wry-banked hen ought to have kept them out of the prize list, as there were other good birds, notably a pair belonging to Mr. Stanley, not noticed, on account of being in the moult, we presume. In the class for Tumblers of any other variety the prize went to Yellows. Jacobins were fair. Fantails were good and plentiful, but in Owls the cup was won by the best pair we have seen. Turbits were not out of the common. Of Barbs there were some good birds, Captain Heaton winning both prizes, but closely pressed by a very good pair of Blacks from a new exhibitor of this breed, Mr. Ord. Of young Barbs there were also some very good birds; but several exhibitors sent two cocks instead of a pair, which, we hear, as well as showing old for young, will be treated with a strong arm at the Palace Show. The first prize went to Captain Heaton for a very ancient-looking cock, the second to Mr. Walker, and the extra second to Mr. Frank Smith for a couple that had evidently had their lower beaks cut. For Dragons the prizes went to Blues and Yellows; and in the class for Any other distinct variety there were good birds of all sorts.

In Rabbits, for the best Lop-eared, Mr. Easton won the cup with a very good specimen. Mr. Hansen won in Silver-Grays, though we preferred those shown by Mr. Roys.

DORKINGS.—Cock.—1, F. Parlett, Great Baddow. 2, B. Dawson, *hc*, H. Woods, Mansfield; Mrs. Seamons, Aylesbury; S. H. Stott, Rochdale. *c*, J. White, Warlaby. *Hens or Pullets*.—1, Hon. H. W. Fitzwilliam, Wentworth Woodhouse. 2, O. E. Cresswell, Idmworth. *hc*, H. Woods; B. Dawson, Leybourne; G. Clarke, Long Sutton; H. Savile, Rufford Abbey; F. Parlett; Henry Lingwood, Barkin, Needham Market.
COCHINS.—Cock.—1 and Cup, Lady Gwydyr, Stoke Park, Ipswich. 2, Horace Lingwood. *hc*, H. H. Bletsoe, Barnwell, Oundle; Henry Lingwood. *c*, W. Sandby, Badchiffon-Trent; C. Sidwick, Ryddlesden Hall, Keighley; H. H. Bletsoe. *Hens or Pullets*.—Cup, Henry Lingwood. 2, J. Dutton, Ipswich. *hc*, Lady Gwydyr. *hc*, W. Sandby; C. Sidwick; H. H. Bletsoe; J. K. Fowler, Aylesbury; Mr. J. Clarke, Long Sutton; J. Cattel; J. Siebel; Horace Lingwood, Crofting, Needham Market; J. Watts, King's Heath, Birmingham. *c*, Mrs. A. Woodcock, Bursley, Leicester.
BRAHMS.—Cock.—1, Horace Lingwood. 2, G. F. Whitehouse. *hc* Dr. H. Haines, Whiteches, Chesterfield. *Hens or Pullets*.—1, J. Siebel, Lark Hill, Timperley. 2, Lady Gwydyr. *hc*, J. Watts; G. F. Whitehouse, King's Heath,

Birmingham; J. K. Fowler; J. Thompson, Netheredge, Birmingham. c. Dr. Holmes.

SPANISH.—Cock.—1, J. Mansell. 2, E. Brown. hc, H. Beldon, Bingley. Hens or Pullets.—1, F. James. 2, H. Beldoo. hc, E. Brown.

HAMBURG.—Gold or Silver-spangled. Cock.—1, H. Pickles, jun., Earby. 2, T. May. hc, Miss C. E. Palmer; A. Woods; L. Wren; S. S. Mossop; T. Walker, jun., c. T. Walker, jun. Hens or Pullets.—1, G. C. Holt. 2, T. Walker, jun. hc, Miss C. E. Palmer; A. Woods, Setton, Liverpool; G. C. Holt; W. Adams, St. Clements, Ipswich; S. S. Mossop; T. Walker, jun.; H. Beldon; Ashton & Booth, Mottram; H. Pickles, jun.; H. Yardley, Birmingham. Gold or Silver pencilled.—Cock.—Cup and 2, H. Beldon. hc, J. Preston, Allerton; H. Pickles, jun.; W. K. Tickner, Ipswich. c. A. Woods. Hens or Pullets.—Cup, H. Beldon. hc, H. Pickles, jun. hc, A. Cole, Long Sutton (2); H. Beldon; R. Parker; H. Pickles, jun. c. J. Preston; A. Woods.

GAME.—Black-breasted or other Reds.—Cup and 1, J. Laming, Spalding. hc, E. Bell, Burton-on-Trent; J. Preston; S. Matthew, Stowmarket. Any other Variety.—1, S. Matthew (Duckwing). 2, J. Laming.

BANTAMS.—Black or White.—1, G. Clarke. 2, S. & R. Ashton. hc, S. S. Mossop; T. C. Harrison, Hull. c. S. & R. Ashton; T. Dyson, Halifax. Any other Variety.—1, S. Lowndes (Pekin). 2, T. C. Harrison (Silver-laced). hc, T. C. Harrison (Gold-laced); H. Beldon (Pekin and Dresden); H. Draycot, Humberstone (Japanese); H. Yardley. c. Rev. A. G. Brooke, Ruyton XI-Towns (Maltese); J. Watts. Game.—Black-breasted Red.—1, E. Steel, Stump Cross, Halifax. 2, G. Maples, jun., Wsvertree, hc, W. Adams; F. Steel; W. F. Entwisle, Cleckheaton; T. Barker; H. Shumach; G. Maples, jun.; J. Eaton, Farnfield. Brown-breasted Red.—Cup and c, W. F. Entwisle, 2, H. Shumach. hc, W. Greaves, Bradford. Any other Variety.—1, W. F. Entwisle (Duckwings). 2, H. Shumach. hc, W. F. Entwisle; J. Eaton (Pile).

ANY OTHER VARIETY.—1, H. Beldon, jun. (Black Hamburgs). 2, Mrs. E. Cross (Creve-Coeurs). 3, H. Pickles, jun. 4, Hon. H. W. Fitzwilliam (Creve-Coeurs). hc, G. T. Phillips (Houdans); G. Sidwick (Black Hamburgs); Hon. C. W. Fitzwilliam (La Fêche); H. S. Fraser (Houdans); W. K. Patrick, West Wynch, Lynn (8) (Polands); Rev. A. G. Brooke (Malay); J. O. Hobson (Creve-Coeurs); S. S. Mossop; J. K. Fowler (French); H. Beldon (Polands); J. J. Malden (Creve-Coeurs); W. H. Tomlinson (Buff Polands); T. Dean (White-crested Black Polands); c. H. Savile (Japanese Silkies); Mrs. Seamons (Silkies). ORNAMENTAL VARIETY.—1, H. Beldon, jun. (Gold Pheasants). 2, and c. H. Savins (Young Silver Pheasants and Silver Pheasants). hc, E. S. Lowndes, Stony Stratford (Gold Pheasants); Miss M. Dodson (Australian Shell Parrots); J. Watts (Silver Pheasants); H. Savile (Gold Cock Pheasants); S. S. Mossop (Foreign Birds); J. K. Fowler; J. Nutt, Long Sutton (Bengal Parrot); G. Clarke (Gold and Silver Pheasants).

TURKEYS (Any Variety).—1, G. R. Pearson, Witham Common. 2, M. Kew, Marks Overton. hc, E. Leech; G. R. Pearson. c, T. M. Derry. DUCKS.—Rouen.—1, H. Beldon, jun. 2, J. White. hc, A. Woods; J. K. Fowler; W. H. Robson, North Riston, Louth (2). Mrs. Clarke (2). Aylesbury.—1, E. Leech. 2, Mrs. Seamons. hc, J. K. Fowler; Mrs. Seamons. Any other Variety.—1, A. J. Trickett (Carolinias). 2, S. Burn, Whitley (Black East Indian). c, S. & R. Ashton (Shell); T. C. Harrison; F. E. Schofield (Black East Indian).

GESE (Any Variety).—1, Rev. G. Hanter, Stillingleet, York. 2, Mrs. Seamons. hc, E. Leech, Rochdale. c, J. H. Barker (Grey).

SELLING CLASS (25).—1, H. Beldon, hc, F. Parlett (Coloured Dorking); E. Brown (Spanish); G. Clarke (Dorking); c, A. J. Trickett (East Indian); C. Layland (Brahma); G. Clarke (Dorking); J. Stephens (Cochins). (27).—1, H. Pickles, jun. (Polands). 2, Mrs. E. Cross (Creve-Coeurs). hc, J. Preston; W. J. Woodhouse; H. Beldon; W. P. Entwisle; W. K. Tickner (gold-pencilled Hamburgs); S. Beighton (Black Red Bantams).

COUPLE OF FOWLS ON DUCKS.—1, S. S. Mossop. 2, G. Clarke (Cross between Dorking Cock and Partridge Cochins Hen). hc, T. E. Cole; G. Skelton (White Cochins and Coloured Dorking); T. M. Derry (Partridge Cochins and Dorking); G. Clarke. c, T. M. Derry.

PIGEONS.

CARRIERS (Black).—Cock.—1 and 2, R. Fulton. hc, W. Massey, Spalding; J. C. Ord, Pimlico. H. Yardley; F. Smith. c, S. Campanin, jun. Hen.—Cup, 1, and 2, R. Fulton, Deptford. hc, T. W. Metcalfe, Cambridge; R. Fulton. c, F. Smith. Any Variety.—Cock.—1, R. Fulton. 2, W. Massey. hc and c, J. C. Ord. Hen.—1 and 2, R. Fulton. Young Birds.—1, W. Massey. 2, G. C. Holt.

POUTRES (Red or Blue).—Cock.—1, 2, and hc, R. Fulton. Hen.—1, 2, and hc, R. Fulton. Any other Colour.—Cock.—1 and hc, R. Fulton. 2, W. Harvey. Hen.—1, 2, and hc, E. Fulton. c, W. Harvey.

TUMBLERS (Almond).—Cup and 1, P. H. Jones, Fulham. 2, J. H. Ivimy, Singfield. hc, F. Key, Beverley; R. Fulton. Any other Colour.—1, R. Fulton (Yellows). 2, W. J. Woodhouse. hc, F. Graham (Beards); W. J. Woodhouse (Baldheads); J. H. Ivimy (Yellow Agates).

JACOBS.—1, T. C. & E. Newbitt. 2, R. Fulton. hc, R. G. Sanders, Leven, Beverley.

FANTAILS.—1 and 2, J. T. Loversidge, Epworth. hc, F. Graham, Birkenhead; H. Yardley; F. Smith. c, W. Harvey; H. Beldon.

OWLS.—1, R. Fulton (White). 2, W. Harvey, Sheffield. hc, P. H. Jones; J. Fielding, Rochdale. c, S. A. Wyllie.

TURBITS.—1, T. C. & E. Newbitt, Epworth. 2, E. T. Drew (Silver). c, G. H. Gregory, Taunton (Blue); R. D. Borne, Boston.

PARBS.—1 and 2, H. Heaton, Worsley. hc, J. C. Ord; J. Fielding, jun. Young Birds.—1, H. Heaton, Worsley. 2, E. Walker. Extra 2, F. Smith. hc, W. Massey.

DRAGONS.—1 and 2, F. Graham.

ANY OTHER VARIETY.—1, G. Sturges (Egyptian Swifts). 2, H. Beldon. hc, F. Graham; I. Fulton; Lady F. Bushby (Blue Runts); W. Harvey; S. A. Wyllie (Rouets); T. C. & E. Newbitt; H. Snaushall, c. — Arkwright (Autwcrps).

SELLING CLASS.—1, G. Roper, Croxson (Jacobins). 2, H. Beldon. hc, G. H. Gregory; H. N. Harvey (Barbs); J. Watts (2); W. Harvey; H. Yardley.

RABBITS.

LOP.—1 and Cup, A. H. Easton (Black and White Buck). 2, J. Irving. hc, A. H. Ersted (Portsmouth Doe); J. Priestly (Fawn Buck); C. Gravill, jun. (Blue); H. J. Tomlinson; E. Vaughan, Birmingham (Yellow and White Spanish Buck); T. Mumbly (Yellow and White Buck); J. Boyle, jun.

ANY OTHER PURE BREED.—1, S. G. Hudson. 2, J. Preston (Himalayan). hc, E. E. M. Roys, Rochdale (Silver-Grey); A. H. Easton (Silver-Grey); K. S. Rothell, Rochdale (Himalayan); S. G. Hudson, Hull (Silver-Grey); J. Boyle, jun. (Himalayan and Grey and White Dutch).

HEAVYS.—1, Mrs. Arkwright (Yellow and White Doe). 2, T. Mumby, Long Sutton (Grey and White Doe). hc, A. H. Easton (Doe); S. Butterworth. c, J. Taylor; E. Vaughan (Grey and White Spanish Doe).

SUBSCRIPTIONS TO THE FRENCH VARIETY CUP AT SOUTHAMPTON.—Mrs. Leopold Paget, 5s.; Mrs. Pattison, 10s.; Miss T. K. Barnes, 5s.; the Rev. N. Bidley, 10s.; the Rev. J. Ward, 5s.; Mr. R. B. Wood, 10s.; Mr. W. O. Quibell, 5s. Total—£2 10s. Any further subscriptions will be thankfully received by H. S. Fraser, Esq., Headley, Liphook, Hampshire.

THE NATIONAL PERISTERONIC SOCIETY.—The meetings for the season 1870-71 will be held at the Freemasons' Tavern,

Great Queen Street, Lincoln's Inn, from 8 to 10 P.M. on November 1st and 15th, December 6th and 20th, January 3rd and 17th, February 7th and 22nd, and March 1st. Visitors are admitted by a member's card, or by writing to the Honorary Secretary, Mr. P. H. Jones, 37, High Street, Fulham, S.W.

TONBRIDGE WELLS POULTRY SHOW.

This Show was held on the 7th inst., and surpassed any previous, shows that have been held here. About 130 pens were exhibited, and next year the Show is to be larger and pens are to be provided, as this year each exhibitor had to find his own pen, which rather diminished the number of entries; nevertheless, the birds were mostly very good specimens, and in some classes the competition was severe.

Spanish headed the list, and a very good class they were. Dorkings, also, were well represented. In Brahmans, Darks were first, Light second, in a generally good class. Hamburgs, for the south, were well represented; the prize pens were all good, and the competition was large. Game were fairly shown, and the first-prize pen excellent; hardly any of the specimens were dubbed. The French class was fine. The first-prize pen came from North Wales. Mr. Dring's Creve-Coeurs seemed well worthy of a commendation, but they had not this honour; his second-prize Houdans promise to be future prizetakers. In the "Variety class" Silkies were first, White Cochins second. This was a large class. The Ducks were all good. The Aylesburys were first-class. Miss Hawler's Pervian drake must have been very early hatched indeed, quite on the daybreak of the 1st of January, as for an 1870 bird he seemed to be in very forward plumage.

There was a fair show of Pigeons. Mr. Yardley showed a pretty collection of six pairs of different kinds. Below is the prize list:—

SPANISH.—1, F. James, Peckham. 2, E. G. W. Stratford, Addington Park, Maidstone. c, F. C. Horv, Tonbridge. DORKINGS.—1, G. Field, Ashurst, Tonbridge Wells. 2, A. Arnold, Lamberhurst. 3, E. G. W. Stratford, c, J. Field, Tonbridge Wells. BRAHMANS.—1, E. G. W. Stratford. 2, H. Mitchell, Catford Bridge, Sussex. c, Miss Kelsey; W. Dring, Faversham. HAMBURGS.—Golden-spangled.—1, W. Taylor, Maidstone. Golden-pencilled.—1, R. S. S. Woodgate, Fennybury, Tonbridge Wells. c, W. Taylor; R. S. S. Woodgate. Silver-pencilled.—1, Mrs. Miller, Tonbridge Wells. Silver-spangled.—1, W. Taylor. c, J. Lopwirth. GAME.—1, Mrs. Lee, Peshurst. 2, J. Jeskin, Eltham. 3, E. G. W. Stratford. c, Earl of Aberghavony. FRENCH.—1, Miss E. Williams, Welshpool. 2, W. Dring. ANY OTHER VARIETY.—Chickens.—1, Miss Hawker, Tonbridge Wells. 2, K. S. S. Woodgate (White Cochins). Adults.—1, J. Field. 2, Mrs. Miller. c, R. S. S. Woodgate (White Cochins). BANTAMS.—1, E. G. W. Stratford (Game). 2, A. C. Ramsden, Ashurst (Japanese). c, F. Hore. TURKEYS.—1, Sir D. Salomons, Barts, M.P., Tonbridge Wells. 2, J. Patchett, Mayfield, Sussex. GESE.—1, A. J. Borsford, Hope, M.P., Redbury Park, Kent. 2, G. Reid, Broadwater, Sussex. DUCKS.—Aylesbury.—1, G. Wax, Frant, Sussex. 2, Mrs. C. Roberts, Frant. c, F. Edgell, Honen.—1, A. Patchell, Mayfield. 2, Rev. R. Hull, Frant. Any other Variety.—1, Mrs. Lee. 2, Miss Hawker. c, A. Patchett.

PIGEONS.—1, H. Yardley, Birmingham. 2, A. A. Meersch, Catford Bridge. Extra 2, G. Ware. c, Mrs. C. Roberts.

Mr. M. Headley, of Redhill, was the Judge.

SCARBOROUGH CANARY SHOW.—Do not forget the entries close on the 15th. The schedule is comprehensive though somewhat condensed, but by liberal support the Committee will be encouraged to extend their prize list next season. It is the second annual exhibition, and I hope will become one of the permanent fixtures in the "northern circuit."—W. A. B.

HISTORY OF THE BRAHMAS.

I GIVE below all the facts relating to the early history of the Brahma Poetra fowls I can call to mind at this late day. At an earlier day I could have given a history of these fowls more satisfactory to myself—i.e., more fully than I can now; nevertheless, so far as it goes, the truth of it cannot be questioned.

1st, Mr. Chamberlaine's Christian name is Nelson H. 2nd, The sailor's name I never made a note of, and cannot give it.

3rd, The ship arrived in New York in September, 1846. The first brood came out in May, 1847. I purchased the most of that brood in August, and the old pair the April following.

4th, The name of the port from which the ship sailed with the fowls on board is Luckipoor. This port is up from the mouth of the Brahma Poetra river, in India. The name of the ship I cannot give, neither can I give the name of the captain. Did not at the time think it of importance, and made no record of it.

5th, The Brahmans were first exhibited in Boston by Mr. Hatch, of Hampton, Conn., under the name of Grey Chittagongs, in 1850. I declined exhibiting mine at that time: I believed them to be a breed different from the Chittagong, and preferred to accumulate stock and test them further before bringing them out publicly.

6th, I attended the exhibition at Boston, and contended that

they differed from the Chittagongs, and should pass under a different name. A committee was appointed, and the name Brahma Pootra given; it being the name of the great river from the banks of which they came. The name was then established.

7th, Weight of cocks, fall-sized, 12 to 14 lbs.; cocks, six to seven months, 9 to 10 lbs. Hens when first introduced 9 to 10 lbs.

8th, I did notice the "pes-comb" on the first birds. It was small. It was not so with all, and yet it appeared different from the comb of the Chittagong.

9th, There was no degeneracy in the birds of my breeding. I had some specimens larger than the imported birds. I sold no birds until December, 1850. I sold at first at 12 dolls. per pair, and soon after from 15 dolls. to 50 dolls. per pair. The price went up as the fowls became better known, and recognised as a distinct breed.

10th, I bred them eight years, when my health failed, and I was obliged to leave all care for a time.

11th, There was a tendency to throw dark chickens, but a greater tendency to become lighter, and yet not white like the White Dorking. All breeds of fowls having dark and light feathers can be varied either way to darker or lighter by choosing always the darkest or the lightest for breeders. If our stock of Brahmas is pure and they are allowed to breed together promiscuously, the variation in colour will be slight. I never bred to either extreme.—VIRGIL CORNISH—(*Poultry Bulletin.*)

THE NEW METHODS OF CONTROLLING THE FERTILISATION OF THE QUEEN BEE.

REFERRING to Mr. Dax's method of controlling the fertilisation of queens, Mr. Kohl, a bee-keeper of Arnstadt, Thuringia, makes the following statement.

"On the 17th June, 1868, Mr. H., a tailor of B—, whom I know to be a thinking and able bee-master, related to me as follows:—

"Last July one of my colonies (which are all domiciled in Dzierzon hives), which I had purposely deprived of its queen, hatched out a young one. I instructed my son, a young man nineteen years of age, and by no means inexperienced in bee-keeping, to watch the bees carefully during my absence in church, and to pay especial attention to this particular hive, the young queen of which I had not yet seen, but whose existence was according to my calculations perfectly certain, and who might possibly take a wedding flight during my absence. On my return my son informed me that the young queen had made her appearance on the alighting-board, and had attempted to take wing, but had fallen down and was still crawling about in the sand. I immediately sought for and found her, when I discovered to my extreme chagrin that although her wings were fully developed, she was perfectly unable to fly. From sheer pity I allowed her to crawl from my hand into the hive. The next day she reappeared, repeated her vain efforts to fly, and again fell to the ground. I took her up as gently as before and examined her minutely, but failed to discover the cause of her incapacity. I observed symptoms which determined me to make an experiment with her.

"For this purpose I confined her under a large tumbler, together with ten drones from another hive. About ten minutes afterwards I looked at her again, and saw evidence that fertilisation had taken place, and could only regret that I had not kept a constant watch upon her. I replaced her in her hive, and three days afterwards I satisfied myself that she was still there, and that to my extreme delight she had commenced egg-laying. From that time the colony increased rapidly, and is now one of my strongest stocks, although still retaining the same queen.

"After this accidental discovery I made a further experiment in April, 1868, being induced to do so by the possession of a stock which had become queenless during the winter. This I supplied with a brood comb so as to enable it to raise a queen, the fecundation of which appeared possible even so early in the season, since I had already found several drones in another hive. When the young queen had hatched out, I placed her with a few drones under a tumbler, where I left her for a quarter of an hour, and saw that in this case also fertilisation had taken place. Both stocks, with queens which have been fertilised under tumblers, are at this moment in the most

flourishing condition, as may be witnessed by anyone who likes to pay a visit to my apiary, and to whom I shall have pleasure in opening my hives and submitting them to inspection."

HOW LONG ARE YOUNG QUEENS IN EMBRYO?

I HAVE read with very great pleasure the various letters which appeared in your columns from the pens of the "DEVONSHIRE BEE-KEEPER" and Mr. Pettigrew on the question "How long are young queens in embryo?" The "DEVONSHIRE BEE-KEEPER" maintains that sixteen days are required for hatching, while Mr. Pettigrew holds with equal tenacity that fourteen days only are necessary for this purpose. I have to congratulate both writers on the fine spirit they show, the evident love of fairplay which characterises their letters, and their earnest desire to arrive at the truth; and while each holds to his own opinion with great firmness, yet I believe great good will be the result by leading others to examine for themselves.

I was anxious to know the opinions of other authors on this rather important matter, and referred to Langstroth "On the Honey Bee," where, at page 46, he says, "The respective stages of the royal bee are as follows: she passes three days in the egg, and is five a worm. The workers then close her cell, and she immediately begins spinning her cocoon, which occupies her twenty-four hours. On the tenth and eleventh days, and a part of the twelfth, as if exhausted by labour, she remains in complete repose. Then she passes four days and a part of the fifth as a nymph." It is on the sixteenth day, therefore, that the perfect state of queen is attained. But at page 66, where he speaks of artificial queen-rearing, he says, "In from eleven to fourteen days they are in possession of a new queen, in all respects resembling one reared in the natural way." So that Langstroth and the "DEVONSHIRE BEE-KEEPER" are agreed as regards rearing by the natural way.

I then opened a somewhat portly volume, Huish on "Bees: their Natural History and General Management," but his chief object is evidently to treat with scorn and contempt the various opinions advanced by Huber, who, perhaps, has done more than any other individual for the advancement of apian science, and who has been very properly named "Prince of Apianians." According to Huish the egg of the queen takes about twenty-two days from the time of its emission from the ovary of the mother queen until the insect arrives at its maturity. See page 80 of his work.

Having now had considerable practical experience, and devoted much time to the study of this branch of rural economy, as well as from frequent observations made in the rearing of queens, both naturally and artificially, I am convinced that, as a general rule, the time occupied in hatching is under sixteen days.

I will now place before your readers my latest experiment on this matter. Being desirous to introduce fresh blood into my apiary, which all bee-masters should occasionally do, I applied to a friend, some thirty miles distant, to see if he could accommodate me with a frame containing eggs, in order that I might raise for myself young queens. This he willingly acceded to, and on the evening of the 17th of August my longed-for treasure arrived, and on the following day, the 18th, was transferred to a hive which contained neither queen nor eggs. On the 23rd I found six cells completely sealed over. Again on the 26th I had another inspection, and found two cells additional, or eight in all. Next day, the 27th, I was under the necessity of going to Arran to take some honey from my hives there, and during my absence I left them under the charge of a friend, in whom I had confidence, and whom I will now allow to speak for himself. "Early on the morning of the 29th (or the eleventh day) I opened your hive containing queen cells, and to my great surprise found two cells empty; one of the queens I found running stealthily along the combs, the other, as was to be expected, I found dead on the bottom of the hive. On the following morning, the 30th (or the twelfth day), I found two more hatched, one on each side of the comb, both alive, but one of them, being weakly, soon died; the other was engaged in a violent and murderous attack upon the cell nearest maturity, and the inmate of which was dragged out dead about midday. An hour afterwards the sixth left its cell strong and healthy. On September 1st (or the fourteenth day) the seventh and eighth made their appearance, and, taking all

things into consideration, I have to congratulate you on your success."

So far, then, this is the result of my latest experiment, and it only tends to confirm the opinions I had previously formed, and which have been already expressed, and now unhesitatingly state my opinion that the maximum time occupied in hatching a queen is fourteen days.—A STEWARTON APIARIAN.

OUR LETTER BOX.

EXCHANGÉ (A. Johnston).—We insert in a special column exchanges desired. If you send twelve postage stamps, and state what you wish, the statement will be inserted in that column.

DORKING COCK'S COMB DISCOLOURED (Dorking).—It is sometimes indicative of failing condition. Sometimes at this season of the year it is caused by the sharp morning frosts, which begin about this time. At other times it springs from eating improper food, or not digesting that which is eaten. In either case your first remedy is to give a tablespoonful of castor oil, follow it with Baily's pills, feed principally on ground oats, and give no whole corn for a time. Dorkings in confinement require more watching than any other breed, and it is beneficial, when this appearance of comb is seen, to give a couple of pills of camphor, each the size of a garden pea.

LEGHORN AND JERSEY FOWLS (M. H.).—We do not know them. People take strange liberties in naming fowls.

COCHIN-CHINA'S FEATHERS PROJECTING (Buff).—In your young cocks you are plagued with twisted wings. They will not come right in moulting. We have tried various experiments, but have never succeeded, and it is, unfortunately, hereditary. As it is an eyesore, you can improve the appearance of the birds (when the new flight feathers are hard) by cutting them off halfway up, and tying them under the rest of the wing. We have two otherwise fine birds that are so disfigured, and are half disposed to pinion them as we do wild fowls. They cannot fly if they will, and they never try to; we think they would not miss that which in their case is mis-called the flight. We have some confined in a large space, separated from a kitchen garden by a rubble wall between 3 and 4 feet high. The goodly Cochins sometimes look up at the luxuriant green food so nearly within reach, and at last make an effort to get over; it ends in a mighty fly that raises them 18 inches from the ground, a vigorous scramble that finds in their reaching the ground breathless and panting for a quarter of an hour. Your birds should be clean moulted by the first week in November. Soft food is always best, and it is cheaper to give ground than whole corn.

CROSS-BREEDING WITH LIGHT BRAHMAS (Jury Coc).—Of the two varieties you name we should advise you to cross with White Dorkings if size is among your desiderata. If you cross with the Game we advise the White in preference to Piles, only on account of colour.

BRAHMA POOTRA'S FOOT SWOLLEN (Anelia S.).—There may have been a little inflammation in the foot, and the bleeding will do it good. In some cases Brahma cocks affect the dainty style of walking, and it is a bad symptom, often ending in being crippled for life. We advise you to poultice it twice and then bind it up. Shut him up somewhere where he can have nothing hard to tread upon until the foot is quite healed, and where there is no perch. If he is only eighteen months old you should be able to depend upon him for this year. If he is older he will hardly recover to be of much use. If the strange gait arose from the inflammation or injury, he will recover. If it is a sort of "string-halt," we should fear its gaining the other leg. As soon as his foot is well let him return to his ordinary life and to his perch.

DARK BRAHMA POOTRAS (N. S.).—L. Wright, Esq., Kingsdown, Bristol, can give you the information.

MIDDLETON SHOW.—Mr. F. Steel informs us, that at this Exhibition he won the cup for the best pen of Game Bantams.

BREEDING TRUMPETER PIGEONS, &c. (A. Z.).—Put a young Black hen, bred from a pair of Blacks, to a dark Mottled cock, and the produce will most probably be a good number of very dark Mottled birds. If you have no Mottled bird, put a White bird to it, but your chance of breeding dark birds will be of course less. Let the Black bird be the youngest. Of all things make out the antecedents of your stock, and know how they were bred, and whether there is good Mottled blood in them. In breeding Jacobins it is best to keep the colours clear of each other.

PARROT DULL AND SLEEPY (H. T.).—Continue to give your Parrot the usual food to which it has been accustomed, except the rice, which withdraw. Give it boiled Indian corn, and add a little canary seed with the hempseed, also mix a good sprinkling of cayenne pepper with the soaked bread. Parrots are fond of fruit and nuts, but too much fruit must not be given, as it is likely to cause too great a looseness. Keep the bird warm and free from draughts, the moulting, no doubt, is the cause of its being poorly.

HIVE DESERTED (T. T.).—We should fancy that the colony had succumbed to a buccardering attack from robber bees, probably after having lost its queen. It is, however, possible that it may have perished from starvation, and we should therefore counsel an immediate extermination of all your other stocks, with the view of ascertaining and supplying any deficiency that may exist in their stores before the approach of winter.

MILK FOR RABBITS (Antony).—Rabbits are fond of milk, milk and water, or water alone, and ought to have some two or three times a week, not much, but about three or four tablespoonfuls for a full-grown Rabbit. In summer, when all green food is dried up, or at best contains not much moisture, they require more liquid, and a few pens soaked in water about twelve hours form no bad substitute for green food for a breakfast once a week; and if a little clean water be added to the peas it will be better for them than drinking the water the peas have been soaked in all night.

COVER FOR HUTCH (Idem).—Tarpaulin (cheap) may be had at any marine store-keeper's; but for a covering for roofs, &c., the felt at 8d. per yard is as cheap and better, especially when covered with gas tar and

fine sand sprinkled upon it before the tar is dry. It will then last for years.

FOOD FOR RABBITS (Idem).—Half a pint of dry food, as oats, bran, &c., with sweet hay and oat straw for a bed, and to eat if they choose; also a little green food, or Swedes and carrots, will be sufficient for a day's food for any ordinary Rabbit. You will soon find what they require and will eat. All Rabbits are not the same as regards the amount of food eaten.

AGE FOR BREEDING (Idem).—If you wish for large, strong Rabbits, nine months will be soon enough for them to pair, and do not let them produce more than four litters in twelve months.

FUR OF ANGORAS MATTED (Idem).—For the hair to be matted in the Angora is a proof they are of the true kind, as length and fineness of hair are always to be desired in this variety. When the hair is matted it can be removed with an iron comb and scissors, being careful when doing so to cause as little pain as possible. The new hair will soon grow again, even if the fur has been cut bare to the skin.

METEOROLOGICAL OBSERVATIONS

In the Suburbs of London for the week ending October 11th.

Table with columns: DATE, BAROMETER (Max, Min), THERMOMETER (Air: Max, Min; Earth: 1 ft, 2 ft), Wind, Rain. Rows include Wed, Thurs, Fri, Sat, Sun, Mon, Tues, and Mean.

- 5.—Foggy, cold wind; densely overcast; densely clouded.
6.—Densely overcast; overcast, fine; clear.
7.—Cloudy but fine; fine, overcast; densely overcast.
8.—Rain; cloudy, very damp; clear and fine.
9.—Very fine; cloudy; showery at night.
10.—Very fine; fine but cloudy; clear and frosty.
11.—Sharp frost; very fine; clear and frosty.

COVENT GARDEN MARKET.—OCTOBER 12.

THERE is no improvement in the trade, but owing to the falling-off in the supply, the price of Peaches and Nectarines is much higher. Peas principally consist of Marie Louise, Gansel's Bergamot, Duchesse d'Angoulême, and Louise Bonne, but the supply far exceeds the demand. Good samples of Tibston, Cox's Orange, and Blenheim Orange Pippins are now being sent into the market.

FRUIT.

Table listing prices for various fruits like Apples, Apricots, Chestnuts, Cherries, Currants, Figs, Filberts, Gooseberries, Grapes, Lemons, Melons, Mulberries, Nectarines, Oranges, Peaches, Peas, Pine Apples, Plums, Quinces, Raspberries, Strawberries, Walnuts.

VEGETABLES.

Table listing prices for various vegetables like Artichokes, Asparagus, Beans, Broad, Beet, Broccoli, Brussels Sprouts, Cabbage, Capsicums, Carrots, Cauliflower, Celery, Celeriacs, Cucumbers, Endive, Fennel, Garlic, Herbs, Horseradish, Leeks, Lettuce, Mushrooms, Mustard & Cress, Onions, Parsley, Parsnips, Peas, Potatoes, Kidney, Radishes, Rhubarb, Savoys, Sen-kale, Shallots, Spinach, Tomatoes, Turnips, Vegetable Marrows.

POULTRY MARKET.—OCTOBER 12.

WE have little to note. There is a fair supply and small demand.

Table listing prices for various poultry types: Large Fowls, Smaller ditto, Chickens, Ducks, Geese, Pheasants, Pigeons, Rabbits, Wild ditto, Hares, Partridges, Grouse.

26	W		55.6	38.5	46.1	18	44	6	43	4	53	8	10	6	2	15	55	299		

From observations taken near London during the last forty-three years, the average day temperature of the week is 57.5°, and its night temperature 33.6°. The greatest heat was 69°, on the 22nd, 1863; and the lowest cold 17°, on the 23rd, 1859. The greatest fall of rain was 0.96 inch.

FERN CASES.

EVERYONE desires to gratify his or her taste for plants, and in their cultivation finds employment, instruction, and health. Incalculable as are the benefits of the soil and vegetation to man, all cannot engage in the extensive culture of plants, but all may derive enjoyment from an individual plant. In the green of Nature the eye finds repose. To have a green thing with life is a joy to eye and mind. White, blue, and red dazzle,

but fail to relieve. All colours we may imitate, but we fail to produce the live green hues of Nature. No colour is so pleasing. These ideas may not find an echo in the country or garden, but what is that we hear from the town? In the sumptuous palace in the square, and through all the villas, terraces, roads, streets, and lanes, down to the dark and gloomy court and alley from which the sun's life-giving rays have long been shut out—is there no cry there? I trow there is, and it is one that calls for the matchless living green of plants. All the paintings in the world cannot satisfy the eye like the living flowers with their many colours and green ground in beautiful relief. Man may keep the plant in health by affording it soil suited for its roots to spread in, and to give support to the leaves and stems: he can water it, keep it from suffering the injurious effects of an atmosphere which is too hot, too cold, too dry, or too moist, and yet he may not go beyond. It is of this that I wish to say something, knowing, as I do, from an apprenticeship served to growing plants in the midst of smoke, dust, and din, the estimation in which they are held by dwellers in towns. In every house and in every place there are those with a love for plants, be they master, mistress, son, daughter, man or maidservant. I might go further, and say what there is where no plant nor flower ever comes, but I shall draw a veil over it.

We know that dwellings are at the best not good places to grow plants in; the atmosphere is too dry, there are dust, obnoxious vapours, currents of air, and the temperature is not always what it should be. Then some dwellings have no windows with south, east, or west aspects, all look to the cold bleak north. Sometimes, owing to surrounding buildings, little or no sun shines on the houses of those fond of plants. Besides this, there are positions where it is impracticable to grow any but a certain class of plants; I allude to cold rooms, staircases, and landings. Happily we have plants suited to every position. Flowering plants require light, indeed sun, but there are also plants which in the elegance of their forms and the beauty of their foliage amply compensate for the loss of flowers. Of all plants for rooms Ferns are the most suitable. Not that they endure better than flowering plants a dry, dusty atmosphere uneven in temperature—quite the reverse; but they may be cultivated in a way that would be destructive to plants that require sun and a genial atmosphere for their proper development and flowering. Ferns, as we all know, delight in a moist soil and atmosphere, with partial

shade. Of the latter they have enough in rooms, often too much, and the former we have to provide. The only method in which we can give them moisture is by covering them with glass. This is done in a variety of ways, or rather with a great variety of forms in the material used; the form is a matter of little consequence, though appearance is of consequence in rooms where there is any pretence to elegance in the furniture. Individual taste differs considerably, and so do Fern cases, so that all can be gratified.

The requisites of a Fern case are—1st, The case should be deep enough to allow of a proper thickness of soil, which in the smallest ought not to be less than 3 inches, nor in any need it exceed 6 inches. 2nd, In addition to depth for soil there ought to be room for drainage, or an open space beneath the soil. The tray, then, should have a bottom of zinc pierced with holes to allow of water running through, and a space of not less than an inch between that and the bottom proper, which, of course, should be water-tight. It is desirable that this receptacle of drainage water should have an outlet, but secured with a screw-plug, so that it can have the water run off at will. 3rd, The case should have a shade of glass closely fitting into the tray or outside it, and sufficiently high for the development of the plant's leaves or fronds. A height of 18 inches is sufficient, and it ought not to be less than 13 inches. It should be made so as to lift off entire, which is best for small cases, and there ought to be holes in the top. One will suffice for, say, a small case of a foot in diameter: for one 18 inches in diameter three are not too many. The holes need not be more than half an inch wide. If the glass top be fixed, then one or, better, both ends should be contrived for opening, being hinged, and made tight-fitting. At the top there should be a sort of brass network its entire length, and about an inch wide. The above is all that I consider is required for the cultivation of the plants. The design may vary according to taste, and yet it must not be carried out at the expense of diminishing the glass—light is required on all sides.

In preparing the tray for the reception of the plants we put in the loose perforated bottom which is to form the upper part of the cavity for superfluous water, and, to keep the perforations free, put on it about an inch of loose material. Gravel or stones, between the sizes of peas and hazel nuts, or larger, will do well, but are too heavy. Cinders answer well after being washed, cocoa-nut fibre is also suitable: but nothing is equal to pieces of charcoal, the smallest size being as large as peas, and the largest of the size of a cob nut. This material having been put on to the depth of three-quarters of an inch or an inch, we are ready for the soil. The soil most suitable is sandy brown fibrous peat two parts, one part fibrous yellow loam, one part silver sand, and one part sandstone of the same size as the charcoal, but with the finer particles not sifted out, but mixed with the soil. These ingredients having been well mixed, chopped, and made small, but not sifted, put them in the tray, raising it slightly in the centre, but not very much; 1 inch rise in 6 is ample. In case the above compost cannot be procured, one almost as suitable is made of old cocoa-nut refuse, with the addition of a

fourth of loam, and a like proportion of silver sand. Cocoa-nut fibre refuse is sometimes employed alone. It answers very well, only some Ferns grow weakly where there is a deficiency of siliceous matter. The soil should be pressed rather firm, and when put in ought to be in such a state as regards moisture that it does not clog, and to keep it from doing so it will need to be only moderately moist.

The planting must be left to the operator; he or she will place the tallest-growing in the centre, and the dwarf at the sides. Avoid overcrowding, leaving room for all to grow, and avoid deep planting, merely covering the roots. Water well at planting, so as to settle the soil about the roots and to make all firm.

With respect to the after-treatment, the shade, of course, must be put on, or the doors closed; then place the case near a window, but not too close—it ought not to be nearer than from 18 inches to 2 feet—and every morning between eight and nine o'clock look at the case, and if the glass is wet and drops are likely to run down to the tray, leave the doors open about half an inch for an hour or so, then wipe the glass dry with a towel, taking care not to injure the fronds, and shut the openings. If, however, the fronds are wet with the condensed moisture of the previous night, leave a little opening until the moisture is dissipated, and then close the case. This, however, will seldom be required, as the glass may be wiped dry, and a little air in the early part of the day will be all that is necessary. If there are no doors, then admit a little air, if necessary, by tilting the glass a little. This may seem a tedious process, yet it may be dispensed with, and the plants will still grow tolerably well; but the growths will perish of that brownness that invariably manifests itself in a badly-ventilated structure, and where constant moisture from condensation settles and remains on the fronds. I have known instances of cases not being opened, nor even watered, for three months. I mention this not for imitation, but as exhibiting the great endurance of this tribe of plants. So long as the glass is only covered with a sort of dew, which does not run down the sides or fall in drops on the plants, there is no need of air. However, I strongly advise wiping the glass dry at least once a day. It gives a change of air if it does nothing else, and keeps the atmosphere from becoming stagnant. The same object as wiping the glass dry will be effected if the opening be left open sufficiently long, but this would dry the fronds too much. The case should be closed at night.

Water should be given as required, so as to keep the soil moist, which it ought always to be, without, however, being very wet. Less water will be required in winter, when the plants are at comparative rest, and the evaporation less than it is in summer, when the plants are growing freely. Every spring the surface soil should be removed as far as can be done without injury to the roots, and a top-dressing given of the compost I have recommended. The water should be run off after each watering.

All dead fronds should be picked off as they appear, and a strict look-out kept for insects. The most troublesome are thrips and scale. The former may be removed with a wet sponge, but for the latter the best remedy is to pick them off with a knife before they become brown and hard. If thrips is very troublesome, it would be well to remove the Fern case to an outbuilding and fill it with tobacco smoke, repeating it two or three times until the insect is extirpated. Green aphids sometimes appear. It is best destroyed by fumigation with tobacco.

Another point will need attention—that is, the shading of the glass from sun, if it strike upon the case, for a few hours during the hottest part of the day. This object is best effected by a piece of muslin placed on the window side of the glass. From September to April shade will not be necessary. If the Ferns grow all to the side next the window, turn the other side to the light, and this ought to be done at least once every week. Of course, if the light be equal from all points, this will not be necessary.

I purpose to conclude with three lists—one of hardy Ferns, suitable for rooms without fires, landings, or other cold situations; one of greenhouse Ferns, or those which may be grown in rooms from which frost is always excluded; and one of stove Ferns, or those suitable for a room never lower in temperature than 50°.

For a Cold Room—*Asplenium Trichomanes*, *A. Trichomanes multifidum*, *A. Adiantum-nigrum*, *Blechnum Spicant* and its varieties *ramosum* and *cristatum*, *Lastrea Filix-mas crispata*, *L. Filix-mas Schofieldii*, *Polypodium vulgare*, and vars. *cristatum*, *bifidum*, *omni-laceraum*, and *cambricum*; *Scolopendrium*

vulgare, and vars. *polyschides*, *ramosum*, *subcornutum*, *multiforme*, *proliferum*, and *foecundum*, and *Lomaria alpina*. The above are all evergreen, and lack the grace and elegant fronds of some of the deciduous kinds, which I must not omit:—*Athyrium Filix-fœmina depauperatum*, *Cystopteris fragilis* and var. *interrupta*, with *C. Dickiana*, are very pretty.

For a Room with Fire—**Adiantum capillus-Veneris*, **Acrophorus hispidus*, *Anemidietyon Phyllitidis*, *Adiantum æthiopicum*, *A. cædulosum*, **Asplenium flabelliformis*, *A. monanthemum*, *Blechnum cognatum* (australe), *Davallia canariensis*, *D. decora*, *Goniophlebium loricum*, *Lastrea acuminata*, *L. glabella*, *Lomaria Patersoni*, **Niphobolus lingua*, **N. pertusus*, *Nephrolepis tuberosa*, *N. pectinata*, *Onychium japonicum*, *Platyloma rotundifolia*, **Pleopeltis stigmatica*, *P. pustulata*, *Polystichum triangulum*, *Pteris serrulata cristata*, *Woodwardia caudata*, and *W. aspera*. Of *Lycopods* or *Selaginellas*, *denticulata*, *nucinata*, *densa*, *ohutua*, and *Willdenovi*.

For a Warm Room.—*Æmisia adiantifolia*, *Adiantum cuneatum*, *A. formosum*, *Asplenium dimorphum*, *A. mexicanum*, *Campylopusium angustifolium*, **C. cæspitosum*, *Diplazium ramicans*, *Davallia elegans*, **Goniophlebium vacciniifolium*, **G. piloselloides*, *G. latum*, *Goniopteris gracilis*, *Hemionitis cordifolia*, **Pleopeltis lycopodioides*, *P. terminalis*, and *Pteris crenata*. Of *Selaginellas*, *africans*, *jamaicensis*, *umbrosa*, *flabellata*, and *dichrous*.

Those marked with an asterisk are very suitable for suspended baskets in the Fern case, and for covering rockwork.

The neatest baskets are, perhaps, the half of a cocoa-nut shell suspended by neat brass chains. Rockwork may be indulged in in a Fern case, and I have seen some very pretty devices of that sort; waterfalls, dropping wells, and even a fountain having a pretty effect when done in moderation. It is possible to overdo them even in a Fern case.—G. ABBEY.

GROUND LEVELLING AND PRACTICAL GARDEN PLOTTING.—No. I.

THESE are a number of works on the designing of flower gardens in circulation at the present time, expounding both the theory and practice of the art, many of them admirable in themselves, but it has never been the good fortune of the writer of these notes to meet with one which literally "begins at the beginning." They either assume that the reader is already acquainted with the theory and practice of geometrical problems, or they are expressed in such elaborate language that the unlettered thousand can scarcely comprehend them. My object is to supply this deficiency. The subject is not here treated as a mathematical one, but as one of a purely practical character. I have avoided technical terms as much as possible, endeavouring by simple language to make myself clearly understood by those for whom this is written. I know from personal experience as well as observation, it is the opinion of many young men that it is necessary to have mastered the whole of the problems of geometry previously to attempting to draw a plan to suit a certain piece of ground, and that to transfer to the ground an intricate design already executed on paper is a task almost as difficult. To be a practical gardener it is not necessary to be a garden artist. Nevertheless, in this progressive age, when education is daily becoming more general, it is essential that every man, be his profession what it may, should understand the rudiments of the theory of that profession. It is at least necessary that every gardener who wishes to attain a good position in his profession should be able to design a plan upon paper to suit such ground as he may have under his care, and also to transfer that design to the ground.

It is not my intention to discuss the merits or demerits of the different styles of flower gardening, but it is obvious that before commencing the laying out of a piece of ground, the gardener must have some definite design, geometrical or otherwise.

My notes being elementary in character, and chiefly designed as an exercise for young men whose only time for improvement is after their day's work is accomplished, it will be found that only a few geometrical problems are introduced, being such as are absolutely necessary for the formation of more intricate designs. These, however, will be soon overcome after a few hours' careful study; but two things are necessary—care and perseverance. The pupil must be careful in referring to or copying the designs, to observe accurately the numbering and lettering of the figures, and he is advised not to be satisfied with mere copying, but from the first to practise the drawing of designs other than those here given, however imperfect his first

attempt may be. He will find that by these means he will be able in a very short time to employ his leisure hours in either copying or designing a plan. He may then take the garden line, pegs, &c., to any spare piece of ground he may have in the garden, and execute the design described.

The greater number of the designs introduced are original, others have been suggested by designs laid out, and a few taken from works already in circulation, but so altered and simplified as to be altogether unlike the original, except in character. In introducing the illustrations, the object will be to arrange them that they may follow evenly from one to another, from the simple square or triangle to the more intricate designs, the manner of transferring them to the ground being explained in the most simple language possible. The pupil is urged to pay strict attention to the geometrical problems introduced—how to bisect a given line, erect a square, form an equilateral triangle, &c., as they will be of infinite use to him in converting a design already executed to a piece of ground of a different shape, and also for their adaptation in the more advanced illustrations. By the time the pupil can draw on paper and execute the designs here given, he will have accomplished much towards the attainment of a more general knowledge.

Having determined upon the site for a flower garden, and the style in which it is to be laid out, the first thing to be attended to is to see that the land is well drained.

LEVELLING.

If the ground presents an uneven surface, or is formed of a sloping bank, either inconveniently steep or presenting an irregular surface, it will be necessary to level it, which may be done in the following manner:—Take a stout peg and drive it into the ground, as *a*, *fig. 1*; take a level—either such as is used by bricklayers, as in *fig. 1*, or a parallel straight-edge containing a spirit tube, commonly known as a spirit level—drive in as many pegs as are required, as *b*, to the same level as the first peg *a*. The level line, *c, c*, is the line required; the ground line, *d*, is the uneven surface of the ground, which requires filling up to the level at peg *b*. As soon as the pegs are in, level the ground with a spade, keeping the earth fall up to the top of the pegs, tread it firmly all over, rake it carefully, and roll it well.

If the ground chosen should be sloping, as *b*, *fig. 2*, two depths must be determined upon, one at the highest, and one at the lowest point. Place a boring-rod at each of these points,

as at points 1 and 3, place another in any point between the two, as the intermediate boring-rod 2. By looking over the top of rod 1 the person holding the intermediate rod can be directed to lower or raise it as occasion may require, until it is brought to the proper level, as rod 2. Rod 1 is supposed to be a little raised by placing some earth under it, for the purpose of getting it to the proper level, *a, a*—that is, the level determined upon. Rod 2 is elevated until the top edge forms a direct line with rods 1 and 3. Rod 3 is placed on the natural ground. The cross piece of rod 3 should be 1 inch broader and higher than the others—that is to say, if rods 1 and 2 are 4 feet high, rod 3 must be 4 feet 1 inch, but a line must be drawn exactly at 4 feet, and the top inch painted black. On looking over rod 1 the black line on rod 3 can be seen more distinctly than the top edge of the rod would be, and intermediate rod 2 can be placed more correctly in a line with the top of rod 3—that is, the under edge of the black, than by looking over the tops of the three rods.

The boring-rod is composed of a thin piece of board about

4 inches wide, half an inch thick, and about 4 feet in length. The head is a similar piece of board placed crossways, but only about 18 inches in length. The upper and under edges of the board must be perfectly straight, and at right angles with the body.

The surface of the ground should be perfectly smooth before commencing to trace the design on it. If it is to be turfed and the beds formed, lay all the lines. Insert pegs along the lines and in the angles of the beds, so as to form guides by which to lay the turf. After the pegs are put in take up the lines and lay the turf, allowing the edge to go 2 inches beyond the line required, so as to have sufficient firm ground to dress and form the edges of the beds. As soon as the turf is all laid roll it well, stretch the lines in the proper places as directed, and edge the beds.

If the site is intended for embroidery or any complicated design, it is necessary when digging the ground to pick out all the stones, as in cutting the edge against which to lay the Box a small stone might cause trouble, by preventing the spade from going into the ground or by breaking the edge.

When the ground is properly level and smooth on the surface, proceed to trace the plan upon it; as each bed is traced insert pegs 7 or 8 inches apart. When the design is all traced and pegged out, lay lines along the pegs, and proceed to cut the edge against which to lay the Box. The edge must be cut perpendicularly, as at *s*, *fig. 3*.

Fig. 3.

Lines of Box embroidery vary in thickness. With regard to

the thickness, the outside lines should first be planted, and then the intermediate space filled in afterwards. As soon as all the box is planted the whole should be clipped to an equal height, and flat at the top, irrespective of thickness. The soil must be carefully taken away from the walks

Fig. 1.

to the depth of 8 or 9 inches; place about 2 inches of cinder ashes over the bottom to prevent the worms from coming through the gravel, place 5 inches of brickbats or any rough rubbish over the cinder ashes, and then 2 inches of good gravel, keeping the finest on the top. When the gravel is all on, roll it well. If the design is too complicated to admit

the roller, a turf-beater will answer.

Should coloured materials be required to give effect in the winter months, the soil must be taken away the same as from the walk, but not to the same depth; 4 or 5 in.

will be sufficient—2 inches of cinder ashes, and 2 inches of gravel—then lay the coloured material on the top, such as Derbyshire spar, coal, red brick ends, &c.—*M. O'BRIEN, Gardener to E. Leeming, Esq., Spring Grove, Richmond.*

HORTICULTURAL FALLACIES.

We hear of a deal of red tape and routine when the doings of our rulers are discussed; how few can shake off the influence of habit and custom in their own affairs. People come here and admire my house, say how light yet strong they are, seem surprised at the cost not having been more, discuss everything peculiar in their construction, and finish by inquiring the name of the builder. The next thing I hear is that an application has been made for a plan and estimate for a house or row of houses on the oldest and most expensive plan on which a glass

shed was ever erected—heavy rafters, moveable lights, high back walls, arches of brickwork for Vine roots to pass into, sunk borders, &c. What possible advantage rafters and moveable lights confer I am quite at a loss to conceive. The disadvantages are very obvious, one would think. The roof is heavier and darker, and much more expensive. Moveable lights mean friction, numerous spaces for moisture to act on wood and paint, and the impossibility of ventilating in rainy weather without letting in the wet, and very often they mean a good amount of drip. How anyone who has seen ridge ventilation, and light grooved sashbars all of a size, forming a fixed and impenetrable roof free from drip in all weathers, taking about half the paint that a roof with heavy rafters requires, costing less, and lasting longer, can go back to the old and stupid plan of building I can never imagine. Want of thought and routine must be the only explanation.

Then, again, how often do we see 2 or 3 feet of soil removed to make a Vine border. Can anyone doubt that a Vine border would not in all cases be better, warmer, drier, if raised above the surface? Again, if the situation be naturally dry or well drained, what possible advantage can there be in laying a bed of concrete under a Vine border, or masses of broken stone or bricks? In low situations, where the land is cold, heavy, and wet, one can understand the necessity, though we must feel surprised at such a situation having been chosen for a garden in the first instance; but in dry and favourable situations what end is sought by such preparation? Has it been found that in farming, for instance, a hard and impenetrable pan under a cultivated soil is an advantage? Or is it thought an advantage to cut off the natural effects of capillary attraction in dry weather? I think there can be no doubt that the Vine is the most easy fruit tree in the world to grow, that it will endure worse and more unnatural treatment than any other tree, or, I am sure, a bunch of decent Grapes would be a much rarer sight, for no plant appears to me so badly used. Instead of copying Nature in its cultivation, every unnatural and expensive plan appears to have been hit upon to increase the risk of failure? When will people throw red tape and routine aside, and think for themselves?—J. R. PEARSON, *Chilwell*.

BEDDING GERANIUMS.

(Continued from page 261.)

NEXT to the Golden Tricolors, and not far behind them in beauty, come the Silver Tricolors. Of these I have but three varieties—Mabel Morris, Princess Beatrice, and Empress Eugénie. They are all three lovely as pot plants, but have done next to nothing in the borders owing to the excessive drought. As this has been my first year's trial of them in the open air, I can say no more than that I hope to be better acquainted with them in the future.

More striking, perhaps, and very beautiful are the Bronze Zonals or Bicolors. Of these I have the following—Goldfinch, Eclipse, Mrs. Bass, Madeleine Schiller, Egyptian Queen, Perilla, Compactum, Beauty of Oulton, Black Prince, Southern Belle, Ebor, Prima Donna, Sybil, and several seedlings not differing much from the latter. Of these, Egyptian Queen has carried off the palm for richness of foliage; its growth, also, has been such as to indicate an improved vigour of constitution. Older plants have grown better than cuttings of last year, and when pegged down have covered the ground very nicely. Next comes Black Prince, which has beaten every other of my Bronzes in vigour and habit, although it has yielded the palm for warmth of foliage to Egyptian Queen. I consider this Geranium a great acquisition, having tried it under very different circumstances, as well under partial shade as in the full blaze of the sun. I can imagine it might grow somewhat rampantly in moister seasons, but by taking off cuttings from time to time during the summer, it can be kept easily within bounds, and it yields them very freely. Another advantage of this plant is the character of its bloom—fine trusses of a rich crimson scarlet on sturdy stems thrown up just above the foliage; nor do the leaves burn and become unsightly as with many others of this class. This is a great fault of Egyptian Queen. Black Prince will also bear pegging down very well.

Of the rest, Sybil is an exquisite Geranium, but I planted it too near some *Echeveria metallica*, which, being a gross feeder, no doubt robbed Sybil of some of its fair share of nutriment. Hence it made but little growth, and remains still on its trial. Beauty of Oulton has been much admired, and has stood the season well. It is a healthy vigorous plant, and will maintain

its ground here for some time, I think, but it comes far below Black Prince in many points of excellence. All the others have disappointed me in various ways, notably Southern Belle and Prima Donna, from which I expected great things, but they were placed in the driest of the dry, and therefore had no fair chance against the others; in fact, one plant of Southern Belle fairly died from want of moisture.

Amongst the elder varieties of this class Eclipse and Mrs. Bass have a charm of their own which makes me retain them. Their paler foliage contrasts more strikingly and looks more brilliant at a distance than some of the finer Bronzes, but they have great faults which detract from their beauty, particularly in the way the leaves fade away and shrivel to a dirty whitish-brown shade: hence their dismissal from the garden is only a question of time.

I defer some remarks I have to make upon the Zonal and Nosegay section to a future occasion.—B. & W.

(To be continued.)

PEACHES AND NECTARINES.

THE season is now (October 11th) over. My last dish of Nectarines was Rivers's Victoria, a large and invaluable sort, and my last dishes of Peaches were the Princess of Wales, Walburton Admirable, and Lord Palmerston, all fine late sorts. There could not have been a better season than the past. The fruits were abundant and of great size. All the trees, except Walburton Admirable, bore great crops. I have no Peaches and Nectarines under glass. All were grown on 6 or 7-foot-high brick walls on east, west, and south aspects. The gardens are nearly as open to violent winds as the Eddystone Lighthouse, Stonehenge, or the Bill of Portland. "D." of Deal, saw the fruits in a young state on July 26th; I wish he had seen them at maturity.

The following are the Peaches grown here:—Early York, Early Victoria, Dr. Hogg, Early Ascot, Early Alfred, Marquis of Downshire, Grosse Mignonne, Royal George, Noblesse, Violette Hâive, B-legarde, Barrington, Nectarine Peach, Prince of Wales, Princess of Wales, Walburton Admirable, and Lord Palmerston. Lady Palmerston, Mr. Radelyffe, Magdala, Golden Frogmore, and Early Rivers were not in crop this year. The old sorts are well known, and, as midseason Peaches, will not be easily beaten.

Dr. Hogg is a splendid early Peach. Early Alfred is a great cropper, early, and good. Nectarine Peach is a jewel; it is as smooth as a Nectarine, of fine form, colour, and flavour; of the late series it is the best of all. Prince of Wales, Princess of Wales, and Lord Palmerston are grand late Peaches. Princess of Wales and Lord Palmerston are here the largest of all the Peaches; both have creamy cheeks with bluish suffusion; they are very late, and very valuable. The above new Peaches were raised by Mr. Rivers. The blossoms of Princess of Wales and Lord Palmerston are the finest of all the sorts here. Early Ascot is a Peach of great beauty, and of first-rate formation and flavour. It is as smooth as a Nectarine. Marquis of Downshire bore (second year) a fine crop. It is later than the former. They are both plants of excellent habit, and do Mr. Sandish great credit. Of these novelties, for a small selection, I name Dr. Hogg, Nectarine Peach, Prince of Wales, Lord Palmerston, and Early Ascot.

If the reader will recollect that Walburton Admirable is a shy bearer, it is impossible for one to burn his fingers with any of the others, old or new; they are hardy, good growers, great bearers, and altogether excellent. There is no Peach here superior to the Royal George for habit. The leaves and triple buds are so near together, that if a man cannot get a crop off it, the sooner he gives up Peach-growing altogether the better. The Prince of Wales, Early Ascot, and Marquis of Downshire have the same good attributes. The Noblesse and Nectarine Peach have been the best in flavour and quality of flesh. Noblesse has but one fault—it is shy of producing leaves.

The Nectarines here are Newington (Rough Roman), Elruge, Violette Hâive, White Nectarine, Murray, and Balgowan. These are all well known, and are excellent. Newington is a clingstone, and one of the richest when ripened to shrivelling. The following are new:—Rivers's White, a week or more earlier than White Nectarine; Rivers's Orange, Rivers's Pine Apple, and Rivers's Victoria, the latest of all. The two last-named I specially recommend; they are the finest of all, and very valuable. Now, if the reader cannot please himself out of the above, I fear nobody else can please him. They are all hardy,

great besrers (I see no difference between Elruge and Violette Hâtive, they appear to be the same, or nearly so), and of excellent flavour. Have which your readers will, they cannot burn their fingers. I thank Mr. Rivers and Mr. Standish for raising such noble fruits.

A good successional selection of Nectarines would be Elruge, Rivers's White, Rivers's Orange, Rivers's Picoe Apple, and Rivers's Victoria. The last brings the season to October 11th.

I conclude with a few observations. I prune the trees on the alternate system, as recommended by Mr. Bichaut in his valuable "Peach Pruner." Unless I wish to fill in a vacant space, few of the shoots are more than 6 or 8 inches long. Some are pinched to two and four full-sized leaves. I disbud but little, and pinch to two leaves for spurs. The same shoot will never bear again. It is, therefore, best to prune short, and leave three shoots 4 inches long at shorter distances than leave a shoot 12 or more inches long. If you cannot ripen a shoot 4 inches long, how can you expect to ripen a shoot 12 inches long? If the winter kills, as is often the case, an unripened shoot, you get a bare space without a chance of succession. I rarely have a dead shoot in winter. Long twigs in "misery" are often sent to me by other people. If nurserymen would shorten the twigs of their one-year-trained trees one-third, these would probably produce fruit the first year after removal. They look, of course, more worth the money untouched. I keep my trees root-pruned, and hence I am able to grow more sorts. If the roots are allowed to ramble, you must permit the trees to ramble, or they will gum. The result is in time a large bare space at the base and centre of the trees. I have "expletives," or small trees, some on short stocks and others headed-off into standards, to fill up all interstitial spaces and gaps. These are kept short-pruned, and are removed annually to be root-pruned, in order to keep head and roots good friends. I stop the extensions in August, and the other shoots in June. All my trees are now nearly bare of leaves, are pruned, and are tied with bast to cast-iron nails. The bast should be crossed, so as that the nail may not touch the twig.—W. F. RADCLIFFE.

THE CULTURE OF LILIUM AURATUM.

This is without doubt the most popular of the Lily tribe, and bids fair to become the most popular of plants, now that its price has placed it within the reach of the humblest owner of a greenhouse. Numerous distinct and beautiful varieties are in cultivation, and a fair field is open to the hybridist, as a most distinct and lovely variety, said to be a cross between *L. auratum* and *lancifolium*, was exhibited at South Kensington lately. As to the varieties of *auratum*, their distinctiveness consists not only in the size, colour, and shape of the flowers, but also in the number of flowers borne on a spike. Some of the varieties have from three to six flowers on a spike, others from thirty to forty. I obtained a number of bulbs of *auratum* of nearly equal size, as imported from Japan, in February, 1867. No notes were made of their growth or flowering in that year, but in the following three seasons the subjoined notes were made. The produce of each bulb was each year reported in a pot by itself.

No. 1.—1868 had 1 spike 16 flowers	No. 3.—1870 had 14 spikes 33 flowers
1869 had 4 " 32 "	No. 4.—1868 had 2 " 13 "
1870 had 6 " 134 "	1869 had 4 " 25 "
No. 2.—1868 had 1 " 25 "	1870 had 9 " 75 "
1869 had 1 " 24 "	No. 5.—1868 had 2 " 9 "
1870 had 2 " 39 "	1869 had 2 " 9 "
No. 3.—1868 had 3 " 9 "	1870 had 2 " 7 "
1869 had 3 " 10 "	

The remaining roots did not succeed well; bulbs were not increased to a large extent, and not more than one or two flowers were borne on a spike. No. 1 had flower-spikes 10 feet in height, and the largest number of flowers on a spike was thirty-five. Some of the varieties do not grow more than from 2 to 3 feet in height, and have the finest individual flowers.

Nearly all the Lily tribe are of easy culture, and *Lilium auratum* is not an exception. October is a good month to repot the bulbs; it is not advisable to dry them off, as is done with Hyacinths, Tulips, and other bulbs. Water ought to be administered sparingly previous to potting, and as soon as the leaves assume a yellow tinge the stalks may be cut over and the bulbs potted. In potting, some cultivators disturb the bulbs as little as possible, merely scratching away the loose soil with a pointed stick, and repotting in a pot a size larger; I consider it best to shake the soil entirely from the roots, separating each bulb, and saving the fresh roots as much as possible. As many as a dozen bulbs are planted in a 13-inch pot, three of

the larger bulbs are placed in the centre, and the remainder round the inside of the rim. I find they succeed well in a compost of three parts of turfy loam and one part of leaf mould and rotted manure, with a portion of silver sand to keep the material open.

If the compost in which the bulbs are potted is somewhat moist, no watering will be required. The pots ought to be plunged in a cold frame, and I do not know of anything better for this purpose than cocoa-nut fibre refuse; and if the pots are completely buried in it, so that there may be at least 4 inches of the fibre over the surface of the soil, there will be no danger of the bulbs being injured by frost. The lights ought to be kept off the frame, except during severe frost and drenching rains. The bulbs will continue to make roots all the winter. The cocoa-nut fibre refuse ought to be removed from the surface of the pots in March, and if the bulbs are doing well roots will be found pushing upwards into it. The plants ought to remain in the cold frame until May, when they can be placed on a hard bottom in a sheltered position out of doors until the flowers begin to open, when they must be removed to the greenhouse or sitting-room. Manure water may be occasionally administered to them, but they will do well without it; of course if they are wanted for exhibition or any other special purpose, extra care must be bestowed upon them. If they have to be removed a distance when in flower, the anthers ought to be wrapped round with tissue paper, in order that the dark brown dust may be prevented from shaking on to the petals, as it sadly disfigures the flowers. I have seen them brought to an exhibition when this precaution has been neglected, and the flowers were entirely spoiled.—J. DOUGLAS.

STOCKS FOR APPLE GRAFTS.

In reference to the inquiry at page 243, and the information kindly given at page 262 by Mr. Scott, we may pursue the subject with profit, I think to its more complete explanation.

We understand the English Paradise to be the Burr Knot and the Nonesuch, both Apple stocks chosen for this purpose. The Crab stocks, Mr. Scott says, are raised from cider pomace—*i. e.*, the seeds washed out of the cider residuum, and are not the true Crab or wild Apple stocks. Doubtless a host of stocks are produced from cider refuse seeds, but are they not called Free stocks as distinguished from Crab stocks in the nomenclature of their class? and is not the Crab or wild Apple cultivated for stocks? If not, we are growing varieties of Apples on other varieties of Apples, just as we do on the Burr Knot and Nonesuch (called English Paradise), and are in the dark how far, if at all, any or each variety of Apple stock affects any other variety of Apple, scion and fruit, grafted upon and produced from its Apple stock of indiscriminate use. Such would not be the case if Crab or wild Apple stocks were used as Crab stocks, as they alone ought to be, and not confounded with Apple stocks: inasmuch we are all duped, as the Apple stocks, the medley of cider refuse seedlings, go by the name of Crab stocks amongst our nurserymen. We can predicate the result, in growth and produce, from the Crab or wild Apple stock (the only veritable stock), and perhaps from the Burr Knot and Nonesuch Apple stocks; but from such a chaotic mass as cider Apple refuse seedlings render, all must be chance and uncertainty throughout—that is, if the stock do—and it does—influence the graft or scion and its fruit for better or for worse. The mischief lies in the sport or variation, apt to show itself in the same fruit on different and haphazard stocks. Do not cider Apple growers cultivate stocks of each reputed cider fruit, on which stocks alone they graft each peculiar cider scion, stock and scion identical, for verity of produce? So I have been told.

The Stibbert stock, too, by Mr. Scott's kindness, we now understand is the Dutch Codlin Apple—Apple on Apple again, subject very likely to uncertainty in truth of produce, inasmuch as Apple stock may affect Apple scion and fruit, as is already suggested.

And I may appropriately ask, If and in what respect the Burr Knot, the Nonesuch, and the Dutch Codlin stocks affect the scions and fruits grown upon them respectively? The answer would indicate what we may anticipate from cider refuse seedling stocks—Apple stocks at a venture.

Here I will digress, and designate the practice of sending out cider Apple seedling stocks for Crab stocks as, if not a cheat, most reprehensible, and demanding attention from the Royal Horticultural Society as likely to spread a mongrel produce over the face of our gardens and orchards.

What the Doucin and French Paradise stocks are is a myth to us. That the Doucin and the French Paradise are distinct stocks is all we can gather, but the species of each stock and in what they differ are still to be described to us. Even Mr. Scott characterises these stocks as a "mélange of sundries"—not a very complimentary reflection upon our neighbours over the Channel, but perhaps not inappropriate to the deserts of the subject before us, and, like too many alien subjects, inaptly adopted for fashion or gain only. Will Mr. Scott, Mr. Rivers, or M. Du Breuil, tell us something about those Doucin and French Paradise stocks?

With Mr. Scott's aid we come to the Pommier de Paradis, a stock in itself, with the merit, at all events, of a candid character, and no duplicity about its identity. Its other merits as a stock are best left to Mr. Scott's own advocacy and experience, able, ample, and reliable alike. The name alone appears to confound the Pommier de Paradis with its ally, or enemy—which, I know not—French Paradise, and would be better changed for its own credit and reputation. In short, call things by their proper names, and let us know what we are doing in our dealings. Honestly and openly say the Burr Knot stock; the Nonesuch stock; the Dutch Collin stock; the Crab (and not Apple), or the English Crab stock; the Caucasian Crab stock, in lieu of Pommier de Paradis; the cider pomace Apple stock; the Doucin stock; the French Paradise stock. Thus we shall have our choice, and the best stocks in time will find their way to the front. As we stand, we are provoked by a maze of fantastical stocks, deceptive to every lover of genuine British pomological produce.—READER.

INFLUENCE OF THE MOON ON RAINFALL.

It is a matter of almost universal belief in the bucolic mind that the moon exerts a very great influence on changes in the weather, and if a particular lunar phase occurs on the Saturday before the harvest, it is accepted as prognosticating a wet season. Men are found saying they have verified the phenomenon for fifty years, and even intelligent farmers accept it as a fundamental fact of meteorology. From an article by Mr. Pengelly, in the *Quarterly Journal of Science*, we extract the following remarks bearing on the subject:—

That the moon is very influential in, or at least closely connected with, all changes of the weather, is a belief at once widely spread and deeply rooted. Our satellite can neither be full, nor new, nor "fill her horns," without, as is popularly believed, causing or indicating some alteration in the state of the weather. If she is caught "lying on her back," or, in other words, if, when she is less than a semicircle, her cusps are pointed upwards so that the straight line joining them is more or less approximately parallel to the horizontal plane, the fact is supposed to be an indication if not the cause of rain. If she submits to be "towed by one star and chased by another,"—that is, if she is between and near two conspicuous stars, so that the three bodies are at least nearly in a straight line, the fishermen expect a storm.

Though meteorologists show no favour to these and many similar beliefs, some of them admit that it is neither unphilosophical nor contrary to fact to regard the moon as a meteorological agent. Thus, Sir John Herschel, from his own observations, regards it as a meteorological fact that the clouds have a tendency to disappear under the full moon, and adds that a slight preponderance in respect of quantity of rain near the new moon over that which falls near the full, would be a natural and necessary consequence of a preponderance of a cloudless sky about the full. M. Arago, who concurs in this opinion, states that the expression "the moon eats the clouds," is common in France among country people, and especially among sailors. The latter philosopher adds that the results obtained from meteorological observations in Germany and in Paris, were that the maximum number of rainy days occurred between the first quarter and full moon, and the minimum between the last quarter and new moon; the ratios being 100:121.4 in Germany, and 100:126 in Paris; but that in the south of France the minimum number of rainy days occurred between the full moon and the last quarter. He concludes with the remark that "the question requires to be examined afresh."

Mr. Pengelly then gives his own carefully made series of rainfall observations, extending over a period of six years, or rather seventy-four complete lunations. From these we find that the greatest amount of rainfall occurred in the second quarter; the greatest number of wet days in the third; while the mean rate

of rain on wet days was greatest in the second quarter. The author summarises these facts as follows:—1, The least average rainfall was in the quarter immediately preceding the new moon, instead of, as Sir J. Herschel supposes, about the full moon. 2, The maximum number of wet days was in the third quarter, and the minimum in the first—thus differing from the results stated by M. Arago to have been obtained in Germany and Paris on the one hand, and the south of France on the other.—(*English Mechanic*.)

COMPARATIVE TRIAL OF PEAS.

With the assistance of a friend, who lived some distance off, to join in the trial, I have grown sixteen varieties. Although in every case but one my crop was larger than his, the relative proportions were remarkably equal. We found, out of the sixteen sorts tested, the Hundredfold stood first without a doubt, and the Imperial Wonder second best; Waterloo Marrows were third in productiveness.

It is but just to add that the general crop of wrinkled Peas suffered very much from blight, which made Fairbeard's Champion of England and Veitch's Perfection show as tenth and fourteenth on our list—much lower than would otherwise have been the case. I have enclosed a list. The first two columns show the number of peas and pods, and the third column the average produce of one plant. The other columns tell the number of days from the date of sowing to the date of first showing above ground, number to the date of ten flowers, and to the date of ten pods of peas fit to gather. Of course there was some irregularity in the time of coming up on account of the peas being sown in different depths of soil. I have arranged them in their order of earliness, and lettered them A to Q for productiveness.

I should be glad if others in different parts of the country would join me in a similar experiment next year.

I also wish to ask advice as to dressing Apple trees affected with American blight. This spring all my trees were detached from the walls and thoroughly anointed with a solution of Gishurst compound, and the walls carefully washed with a mixture prepared according to your directions, but in spite of all this, I never saw any trees so entirely covered as mine were this autumn.—E. G., *Leighton Buzzard*.

FLOWER-BED ARRANGEMENTS.

We are so pleased with your reply to our letter in the *Journal* of September 8th, and the friendly criticisms of Mr. Peach in that of the 22nd of the same month, that we trouble you again. We must thank you and Mr. Peach, through the medium of "our *Journal*," for your criticism; and with the suggestions you each offer, and the re-arrangement we had made on our coloured plan, we hope next year to have the *tout ensemble* perfect. We omitted to say in our last that beds 8, 9, 10, and 11 (see page 186), have a plant of *Humea elegans* in the centre, and 8 and 9 are carpeted with *Viola cornuta*, though the *Geraniums* have grown so vigorously that only a few flowers of the *Viola* are seen peeping above the white foliage. The alterations you suggest relative to clumps 6 and 7 we think would be an improvement, and father says when the summer bedding plants are taken off, before we plant our spring flowers and bulbs, the beds shall be formed according to the suggestions of the Editors.

The design respecting which we now seek your advice, and of

which we enclose a copy, is situated directly opposite our cottage, and only separated from the highway by a low row of palisading. The enclosure containing this flower garden is but small, and the beds but few in number, yet in this spot we concentrate our choicest plants, and at all seasons of the year we try our best to make it a spot of surpassing beauty. There is not a day throughout the year that the beds are unoccupied, for if in the morning we clear them of the summer plants, before evening we furnish them with others that have to remain through the winter, to cheer us with their pretty blooms in the spring, and *vice versa*. The walls of the cottage are mantled with Roses, Clematises, Cotoneasters, &c.

I will now tell you how the beds are planted, and afterwards make a few remarks respecting the properties of the different plants employed for decoration. The beds are planted as follows:—Bed 1, *Ageratum*, blue, a small variety between the old *A. mexicanum* and the new Imperial Dwarf, edged with Golden Feather *Pyrethrum*. Bed 2, *Geranium* Flower of the Day. Bed 3, *Geranium* Flower of Spring. Bed 4, *Geranium* Douglas Pearson (scarlet). Bed 5, *Geranium* William Thomson (scarlet). Bed 6, *Geranium* Sobieski (scarlet). Bed 7, *William Underwood*. 8, a narrow border in front of the cottage, is planted with a row of *Sedum Fabaria*, edged with *Echeveria secunda* and *Sempervivum californicum*. This bed is our first attempt at subtropical gardening, and as we do not like it we shall give it up. 9 is the gate.

For our spring display we had the following:—Bed 1, Centre of the bed *Alyssum saxatile compactum*, edged with two rows of *Aubrietia deltoidea*, and the whole of the spaces between the *Alyssum* and *Aubrietia* filled with choice *Tulips*. Beds 2 and 3, *Arabis lucida variegata*, edged with red *Daisies*, and filled with *Hyscynth*s.

Beds 5 and 6, *Cliveden Blue Pansies*, filled with *Tulips*. Beds 4 and 7, *Double red Hepaticas*, also filled with *Tulips*. As the *Hepaticas* had ceased blooming early, when they were over we took them away and introduced *Primroses* in their places. The narrow border, 8, had *Wallflowers* edged with *Pansies* raised from seed the previous season, with *Narcissus* introduced among the *Wallflowers*.

Nothing could surpass the beauty and usefulness of the seedling *Pansies*. The spring flowers were exceedingly beautiful, and we think even more charming than the summer flowers; indeed, when one of the most able contributors of "our Journal" came to see us during the last week in April, he declared it to be one of the best examples of spring gardening he had seen. Now, the frosty mornings have already begun to tell upon our present display, and as we have our reserve garden filled to overflowing with spring flowers, we want you to assist us in our arrangements. What we want is perfection, and any suggestions you can offer, either for spring or summer embellishment, will be considered a great favour.

Just a word or two on the merits of a few of our favourites. To enter into full particulars respecting the various plants we employ would too much increase the extent of this paper. We will just briefly refer to one or two of the most prominent, and devote a paper to the rest hereafter. Too much cannot be said in favour of *Douglas Pearson* and *William Thomeon*. These were large plants when we turned them out in the spring, and they have kept the lead of all others ever since. They produce large trusses of crimson scarlet flowers; we have counted nearly one hundred flowers to a truss. They surpass *Bayard* in size and uprightness of habit; and, therefore, we set them down, notwithstanding our friend Mr. Peach's opinion, as the best two *Geraniums* in cultivation. *Bayard* has been as good as ever this season, and *William Underwood* better than usual. We admit *Waltham Seedling* to be good, yet the individual trusses are small, and we consider one fine truss of *William Underwood* to afford as much pleasure as twenty trusses of *Waltham Seedling*. For Mr. Peach's information, among

those we consider not worthy of a place in our flower garden, we may mention *Lord Palmerston*, *La Grand*, *Herald of Spring*, *Cybilster*, *Dr. Lindley*, *Clipper*, *Christine Nosegay*, and *Indian Yellow*. Our other remarks we will reserve for another paper.—*SURAH ANN*, *CLARA*, AND *AMY ALICE*, *Geranium Cottage, Bouth*.

[We like the spring gardening so much that we would rather not meddle with the arrangement, further than to say that dotting with *Hyalinths*, *Tulips*, and *Narcissi* beds pretty well carpeted already, will have a fine effect. Even in summer grouping the carpeting of the ground with a low-growing telling plant, and then having the main plants that show at a distance rather than, has such a good effect that it ought to be more practised. We adopted it once to a considerable extent, but have not much done so lately. It is a good plan for preventing such a thing as blanks in a flower bed, and preventing even the earth being seen. All low-growing plants are suitable for this purpose, as the different *Carastiums*, such *Verbenas* as *Maonetti* and *pulehella*, *Variegated Alyssum* pegged down, &c.]

The much-prized front flower garden—which we like all the more because separated merely by a low palisading from the highway, as thus every passer-by may enjoy its beauties and be tempted to make similar efforts—is set on a parallelogram of lawn, and consists of seven clumps, a large circle in the centre, rather more than a quarter-moon on each side of it, and two smaller circles at each end. Now, the first idea that strikes us is, that your central circle is too large for the other beds, and if the colours used in it were very bright the central bed would at once arrest the eye. You seem to have had this idea present to your mind, as you fill the most of this large bed with a dwarf *Ageratum*, very nice though dull in colour, and edge it with the *Yellow Feverfew*, and thus you prevent the large bed from what we call drowning the other beds. Besides the dullness of such a mass of *Ageratum*, we have this objection to the dwarf variety, which we presume you have, that it is apt to die off or become shabby rather early in the autumn, if you cannot give it water. Of course, we speak relatively as to size, as we do not know the exact

dimensions of the beds, only we see that the central clump is more than double the size of any of the rest. This may have led you to border that clump and leave the others unbordered, or without edging; but that is scarcely enough to restore the balance of size, and, therefore, that central figure would be better broken up so as not to show a mass of any one colour. Thus you might have four bands—a centre of *Coleus*, a band of yellow *Calceolarias*, a band of your dwarf *Ageratum*, and an outside band of the *Golden Feverfew*. Then, again, the central bed might be twice crossed with *Coleus* or *Iresine Lindeni*, filling up the four angles with the *Feverfew*, and having an edging round of *Variegated Alyssum* and *Lobelia* mixed. If the plants in your other beds were not too high, this central circle would look very well if the centre were made into a star, the bulk and the rays of the star filled with the *Golden Feverfew*, the six angles nestly planted with *Iresine Lindeni*, a rich purple that stands nipping to any height, and then a mixed edging of *Alyssum* and *Lobelia* all round. By drawing and painting such a figure you will judge better how it will look. Then, again, as you propose to edge this bed, we would make it a kind of key note for edging all the rest. The edging makes every bed complete in itself, and gives it a finish which nothing else will, it matters not how small the edging be.

We are a little in doubt whether, after making the large central bed somewhat neutral in its tints, it would not be as well to make the half-moons, 2 and 3, of the bright scarlets with appropriate edgings, and have the lighter-coloured foliage, as *Flower of the Day*, at the ends. In this case one circle at each end might be silver-variegated and the other yellow-varie-

gated. Even on the plan you have adopted, with light variegated foliage in 2 and 3, we would band them with a purple, as Purple King Verbena, or with strong plants of the Alternanthera, and if the end circular beds were scarlet we would band them with the larger Cerastium, or, better still, with the Cineraria maritima or the white-leaved Centaurea kept dwarf and close, and for this purpose the Cineraria bears nipping well, and, on the whole, we prefer it for its handsome cut leaves to the Centaurea, whilst it is next to hardy in most dry places.

We will not enter into your comparison of scarlet Geraniums; we may merely say, that in small gardens it is well to encourage the best sorts, and those having the best trusses. But when dense masses of bloom are to be desired rather than fine individual trusses, and if the place is exposed to wind, then we would be sorry to throw away some of the kinds you reject, as Cybister, Indian Yellow, Lord Palmerston, and the old pink Christine. We often find that these smaller-trussed kinds produce the richest mass of colouring, and they are less influenced by wind and rain. Though growing much better kinds, we have had nothing that has equalled Christine for masses of pink. Even now, on the 8th of October, and notwithstanding all the dryness, some beds are beautiful.]

EARLY FROSTS.

In this locality, on the nights of the 10th and 11th of this month, we had two rather sharp hoar frosts for the early days of October, and on the morning of the 12th the thermometer stood at 27°, or 5° below freezing.

This frost has proved destructive to many things, such as Vegetable Marrows, Scarlet Runner and Dwarf Kidney Beans, late Peas, &c.; while in the flower garden such tender plants as Heliotropes, Tropæolums, Iresines, and Perillas have been killed to the ground; therefore when these tender subjects have contributed largely to the beauty of a design the pleasure of viewing them may be said to be over for one more summer, but not so when the less tender plants of the Pelargonium class, Calceolarias, and the like have been employed. These, if the weather should prove favourable, and if the plants be cleared of their dead leaves and flowers, will considerably revive and be tolerably gay for two or three weeks; so that in looking at things one way it does seem to me to be a pity that the present style of bedding should necessitate the use of so many tender sorts of plants which very early frosts destroy, rendering a design that perhaps may be at its greatest beauty suddenly unsightly; yet the hardier kinds of plants retain their beauty for some time longer; but I suppose there is no help for it.—THOMAS RECORD, Hatfield Park.

PORTRAIT OF MR. RIVERS.

SOME friends of Mr. Rivers, of Sawbridgeworth, being desirous of expressing their appreciation of the valuable services he has rendered during a long life to the cause of horticulture by his numerous writings and discoveries, have united in a subscription to procure a portrait as a suitable memorial of one who has contributed so much to the pleasure and enjoyment of his fellows. The portrait has already been commissioned, and it is intended when completed to offer it to the Trustees of the Lindley Library, to be hung at South Kensington.

As Mr. Rivers's consent to the memorial has been obtained on the express understanding that no special application will be made to the general public, but that it shall be a spontaneous movement on the part of those contributing, no application of any kind will be issued asking anyone to assist; but all who have that feeling of regard and admiration for Mr. Rivers, by which the promoters of the movement are actuated, are invited to forward their subscriptions to Dr. Hogg, 99, St. George's Road, London, S.W.

As an illustration of the feeling of many amateur horticulturists who have derived so much healthful recreation and unalloyed pleasure from the pursuit of horticulture, as it has been popularised by Mr. Rivers, we give the following extract from a letter received by Dr. Hogg, from one of the early promoters of this memorial:—

"I am decidedly opposed to testimonials after a man is dead. The dead must depend on their own works for their fame, but the living are capable of receiving pleasure from finding that their exertions for the public good have been gratefully received. If ever there was a man who has diffused

pleasure to mankind, or, to use Virgil's expression, '*qui suis memores alios fecere merendo*,' it is Mr. Rivers. We now associate Mr. Rivers so entirely with orchard houses, that we are apt to forget his earlier but not less useful services in the introduction and cultivation of Roses and Pears, and above all root-pruning. He has managed to blend in a most unusual manner commercial advantages to himself with liberality and instruction to the public."

The following have already intimated their desire to unite in the movement, and have forwarded their subscriptions:—

	£	s.	d.
JOURNAL OF HORTICULTURE, Proprietors of	5	0	0
Hole, Rev. S. Reynolds, Caunton Manor	5	0	0
Kingsley, Rev. W., South Kilvington	2	2	0
Paul, Mr. William, Waltham Cross	1	1	0
Pearson, Mr. John, Chilwell	1	1	0
Radclyffe, Rev. W. F., Okeford Fitzpaine			
Roden, Dr., Kidderminster	2	2	0
Sparkes, George, Esq., Bromley	1	1	0
Speed, Mr. Thos., Chatsworth Gardens	1	1	0
Wilson, G. F., Esq., F.R.S., Heatherbank			

Whatever amount of money may be received in excess of the price of the portrait will be appropriated to some horticultural object of which Mr. Rivers may approve; but Mr. Rivers will regret any proposition that may assume the form of a testimonial being presented to him.

WINTER-BLOOMING ORCHIDS.—No. 9.

ADA.

A. AURANTIACA.—A solitary species represents this genus, and until quite recently it has been extremely rare. During the past twelve or eighteen months, however, a considerable number of plants have been introduced to this country in a living state, and it should be eagerly sought after by those Orchid-growers who appreciate the winter-blooming kinds; for not only is it very distinct and beautiful, but the colour is one rarely to be met with amongst plants of this order. To those unacquainted with *Ada aurantiaca*, the fact of its being so rare may, perhaps, be attributed to some difficulty or peculiarity in its cultivation; such, however, is not the case, for it succeeds admirably under similar conditions to *Odontoglossum Alexandrae*, and the fact of its remaining so long amongst our rarest plants is solely to be attributed to the difficulty attending its introduction, and to its being extremely local in its distribution.

This elegant plant produces slender, somewhat cylindrical pseudo-bulbs, which are about 3 or 4 inches long, and support two or three dark green linear leaves varying from 3 to 6 inches in length. The pseudo-bulbs are sheathed at the base with ferruginous scales. The longest scape I have seen measured about 10 inches, and was produced from the top of the pseudo-bulb, and nodding. The flowers are arranged in a somewhat distichous manner, and placed distantly on the spike; sepals and petals lanceolate, tapering to a narrow point, the petals much the smallest; all of them, together with the lip, are of a rich golden orange, a colour which is extremely rare, and very welcome at the dullest time of the year. It blooms during the months of January, February, and March, lasting in perfection a considerable time. Native of New Granada, at considerable elevations.

ANGRÆCUM.

All the species of *Angræcum*, as far as I am aware, are peculiar to Africa or the African islands. Of late years these plants have been undeservedly neglected by growers of orchidaceous plants, from no other cause that I can imagine than lack of brilliant colours. This is much to be regretted, for many of the species are noble-growing plants, and are very ornamental even when destitute of bloom. *Angræcums* should be grown in the East Indian house, should be provided with good drainage, and be potted wholly in sphagnum moss, which is best for their roots when in a growing state, independent of the pleasing effect it produces.

A. SESQUIPEDALE.—I place this species at the head of the list, for it unquestionably produces the finest flowers of any of the genus as yet introduced to cultivation, and they were first seen in this country about thirteen years ago. The plant is very ornamental; leaves about a foot long, arching, bluntly bilobed at the apex, and very deep green in colour, over which a mealy whiteness is suffused, as if dusted or powdered. The scape is produced from the axils of the leaves, and bears from three to

five thick, waxy-looking, sweet-scented flowers, each measuring upwards of 7 inches in diameter; sepals and petals broad at the base, tapering to a long narrow point; lip ovate, acuminate, and, as well as the sepals and petals, ivory white, tinged with green. The long spur of the lip, so characteristic of this genus, is developed to an extraordinary degree in this plant, reaching 14 and even 18 inches in length, and this has given rise to the specific name. It blooms during midwinter and lasts a very long time in perfection. It bloomed for the first time in Europe in the year 1857. Native of Madagascar.

A. EBURNEUM.—This is also a native of Madagascar, and being a plant of noble growth is a grand ornament in a collection, even when not in flower. It is erect in habit, and an abundant bloomer during winter. The leaves are thick and fleshy, from 12 to 18 inches in length, and about 2 or more inches broad, light green, slightly dusted with a white powder. The long spike is erect, bearing large ivory white flowers, the lip of which is furnished with a long spur. The blooms are of great substance, and remain a very long time in perfection.

A. VIRENS.—By some authorities this is considered a variety of the preceding; however, be it a variety or species, it is very ornamental and distinct. The habit of growth is similar to *A. eburneum*, but the leaves are scarcely so long, and very deep green. The flowers, though large, are smaller than those of the previously named plant, and are produced during the winter months. Native of Madagascar.

A. BILORUM.—A somewhat small-growing plant, but very elegant and distinct, and well deserving more general cultivation than has hitherto been accorded it. The leaves are arranged in a distichous manner, and are thick, dark green, obtuse at the apex. The spikes are pendulous, bearing white flowers, and the lip, as in all this genus, has a long spur or tail; they are produced during the autumn months, and with a few small fronds of *Adiantum* intermixed, they form chaste and elegant wreaths for adorning ladies' hair, and the individual flowers are charming adjuncts to a bouquet. *A. bilorum* is a rather delicate-rooting plant, or what is often called "miffy," and I have found it succeed best when planted in pieces of charcoal and of broken pots only, with just a slight covering of sphagnum moss. It is a native of the west coast of Africa.

A. PELLUCIDUM.—This is the last species of the genus which I shall introduce here as a winter bloomer. There are, however, one or two others which bloom during this season, and are extremely beautiful, but being of recent introduction and still very rare in cultivation, I have had no experience with them, and cannot, therefore, speak of them practically. The present plant resembles *Phalenopsis grandiflora* very much in growth, but the leaves are thinner in texture, from 12 to 18 inches long, and broadest at the apex. The spikes are slender and pendulous, bearing small white pellucid flowers, produced in great abundance, but even without these it is very ornamental. Native of Sierra Leone.

BARKERIA.

A genus of small-growing plants with elegant, and in some instances bright-coloured flowers. This, combined with the fact of their thriving under very cool treatment, should render them general favourites with all growers of orchidaceous plants. *Barkerias* succeed admirably upon blocks of wood, and require only a very small quantity of moss to fix them, but they enjoy an abundant supply of moisture, both in the atmosphere and about their roots. In winter the temperature may fall as low as 40°, or even lower, without producing injury, and in summer as cool and shady a place as possible should be assigned them. During the period of rest they lose most of their leaves, and at this time less water is necessary; but I am not an advocate for drying them much at any season.

B. SKINNERI.—This and its variety *superba* are, perhaps, the brightest and most lovely of their race. The stem-like pseudobulbs are about 12 inches in length, bearing narrow dark green leaves. The racemes of bloom are produced from the apex, and are erect, and from 1 foot to 1½ foot in length. The flowers are numerous; sepals and petals bright rose; lip a richer shade of the same colour, faintly streaked at the base with yellow. It blooms during midwinter, continuing in full beauty for two months with ordinary care. Native of Guatemala, at considerable elevations.

B. LINDLEYANA is not, strictly speaking, a winter-flowering plant, but as blooms are produced during the months of October and November, at which season flowers are very acceptable, it deserves more attention than is usually accorded it. In growth this plant somewhat resembles *B. Skinneri*, but is scarcely so robust, and it should be treated to a temperature a few degrees

higher than is necessary for that species. The flowers are produced in long terminal racemes, which remain a long time in perfection; sepals and petals rich purple; lip white in the centre, bordered with purple. Native of Central America.—**EXPERTO CREDE.**

NEW BOOK.

Choice Stove and Greenhouse Ornamental-leaved Plants. By B. S. WILLIAMS, F.R.H.S., &c., Victoria Nurseries, Holloway, Vol. II.

The first volume is confined to the flowering plants of the stove and greenhouse, and this is a worthy continuation of the work. The best service we can do it is to publish an extract that our readers may appreciate its contents.

ALOE.

A genus of succulent plants, admirably adapted for the greenhouse or for window gardening, containing many species of great beauty, and belonging to the order Liliaceæ. The larger-growing species with scarlet tubular flowers are the most showy, and there is a quaintness about the general habit of some of them which strongly recommends them to the cultivator. The smaller groups separated from *Aloe*, such as *Apicra* and *Haworthia*, contain many little vegetable gems, while another group, *Gasteria*, contains larger, more grotesque, and in some cases handsome-flowered species. They all require to be potted in well-drained soil, which should be mainly of a loamy texture.

A. abyssinica.—A majestic-looking plant, the leaves of which are very thick and fleshy, some 2 feet in length, and 6 inches in width at the base, tapering to an obtuse point, and there slightly incurved, dull green, and clothed at the edges with somewhat distant blunt spines. Native of Abyssinia, about Magdala and other places.

A. arborescens.—This is a very distinct and handsome species. Stem tall; the leaves are slightly spreading, lanceolate, recurved at the apex, and glaucous, margined with green. A very desirable plant. Native of the Cape of Good Hope.

A. plicatilis.—A very distinct and ornamental plant. Its leaves are thick and fleshy, tongue-shaped, and obtuse at the apex, glaucous green in colour, and arranged in a distichous manner, which has given rise to the popular name of "Fan Aloe." It is called by some *Rhipidodendron plicatilis*. Native of South Africa.

A. socotrina.—This is an elegant branching species. The leaves are somewhat erect, narrow, lanceolate, and glaucous green in colour, sparingly clothed with white spines. It is a native of Arabia and Cape of Good Hope.

A. variegata.—Leaves imbricate, somewhat spreading, and arranged in three rows, ovate in shape, and keeled at the back, in colour bright green, with transverse bands and streaks of grey and glaucous green. It is often called the Partridge-breasted Aloe. Native of the Cape of Good Hope.

POMOLOGICAL GLEANINGS.

STANDISH'S MARQUIS OF DOWNSHIRE PEACH is decidedly one of the finest Peaches I have ever fruited as regards size, colour, flavour, and habit. The fruit has been tasted by several persons in my neighbourhood, all of whom will bear testimony to its excellence.—**OBSERVER.**

ALTON TOWERS.—No. 2.

THE SEAT OF THE EARL OF SHREWSBURY AND TALBOT, ALTON, STAFFORDSHIRE.

At the head of the lake, a short distance from the Gothic temple, stands a long, square-shaped, glass structure with a span roof. This was formerly an orangery, but is now divided into three compartments, those at each end containing Peach and Nectarine trees trained-up under the roof on curved trellises, and the central compartment is a Fig house. The Fig trees were a fine healthy collection of bush-shaped trees, bearing a heavy second crop of fruit, and I was told that the first crop had been equally fine. The Peach and Nectarine trees were in excellent condition; the whole of them had a full crop of very fine fruit, and the wood, growth, and foliage were all that could be desired. Elegant columns of stone between the front sashes of this building impart to it an air of dignity and importance well suited to the commanding position which it occupies. The sides of these columns within the house were covered each with a flourishing plant of some choice Tea Rose, growing in a square wooden box neatly faced with Fir bark, and placed on the floor close to the base of each column.

Returning now, we descend the left side of the valley, and pass the grand terrace, the golden gates, and the hath garden—a small flower garden with a pretty fountain, whence a picturesque view offers itself of the alcove with its graceful statu-

ary, and part of the grand conservatories (*fig. 5*). This illustration will serve, perhaps better than any other, to convey to your readers some idea of the rich variety of the works of art with which these gardens abound, and the various aspects under which the same features of the place may be viewed from different points. As another fine example of this, *fig. 6*, presenting a glimpse of Alton Towers from the lower terrace, may be alluded to here.

Some beds of tropical plants near the bath garden were very good; amongst them were some fine masses of various kinds of *Ricinus*, *Solanum robustum*, with handsome foliage, which, together with the yellow stems, was thickly studded with sharp spines; *Solanum Warszewiczii* was also very fine. None of the pretty *Alternantheras* had succeeded very well here, but I am glad to say Mr. Rabone purposes giving them another trial.

Along the side of the walk leading to the lower terrace, a novel and pretty effect was produced by training *Rosea* on a trellis of low iron arches, between every two of which were pretty little vases containing interesting masses of compact dwarf plants. The *Roses* were not kept trim and close, but were to a certain extent suffered to present a wild rambling appearance by no means unpleasing. The numerous fine specimens of the beautiful Hemlock Spruce (*Abies canadensis*), scattered along these lower slopes are very attractive and graceful objects.

Glimpses of the pagoda (*fig. 7*), may be had from many different points, and it is, consequently, seen under a variety of aspects. From the Gothic temple its top is just visible through the trees; from the conservatory terrace it presents itself in a very favourable guise; but it is when we reach the sheet of water in which it stands down in the valley, that the singularity of this oriental structure may be best appreciated. The position is admirably chosen, for the bright colours and gilding with which the pagoda is decked out, tell well against the masses of dark-leaved Firs behind; the descending spray from the single jet of water

Fig. 5.—The Conservatory and Alcove.

Fig. 6.—Alton Towers from the Lower Terrace.

mingling with the *Rhododendrons* and shubby undergrowth of

thrown upwards from its top adds to the effect of this uncommon scene.

Ascending the right side of the valley by winding walks and flights of steps, about half way up a seat is placed, close by some magnificent pyramidal specimens of English Yews, the fine proportions of which do great credit to the care and skilful pruning which must have been constantly bestowed on them.

Coming up from among the trees to this spot, on turning to the opening left between two of these tapering Yews, which, with their companions, are so dark, solemn, and massive, and beholding the splendour of the scene, of which, perhaps, more can be realised at a glance here than from almost any other position, we fancy ourselves gazing through the portals of gloomy night out on the brightness of the dawn.

"For sight no obstacle finds here, nor shade, But all sunshine."

The eye, soothed and rested by the greenery of the banks, the overhanging boughs, and the densely packed foliage shutting in the path by which we ascend,

"Looks down with wonder at the sudden view, As when a scout, Through dark and desert ways with peril gone All night, at last by break of cheerful dawn Obtains the brow of some high climbing hill, Which to his eye discovers unaware The goodly prospect."

The Gothic temple peeping out of the trees, the pagoda, the conservatories, and the alcove, all are visible from here, and I was forcibly reminded of the large engraving in London's "Encyclopaedia." The scene there portrayed was before me in its most important details, recalling many a boyish dream, for often when studying the pages of that masterly work have I lingered over that picture of wonderland so marvelously fair.

Higher up, the Hillside is clothed with vast numbers of *Rhododendrons* in fine health and vigour, seedlings from them growing with the freedom of weeds. The walks wind upwards in the most picturesque manner imaginable, diverging in various directions, sometimes by Fern banks alternating or

the wild woodlands, or between steep moss-clad banks verdant and cool, or else to some opening through the trees affording glimpses of scenes of beauty.

The whole of these delightful grounds are thrown open to the public, and it is very gratifying to know how thoroughly the generosity of the Earl of Shrewsbury is appreciated, for Mr. Rabone told me that very little damage had been done to any of the works of art or plants since he had charge of the gardens.

A door in the courtyard wall near the grand entrance opens on to a walk leading to a long wire arcade covered with Roses and Honeysuckles. At one extremity is an elegant alcove of stonework, with windows of stained glass, forming a charming secluded resting place, while at the other end is a flight of steps leading upwards from this retired spot to a broad promenade along the top of an embattled wall, over which the delighted glance sweeps down the valley, which is seen offering a charming general view of its rich and fanciful combination of works of art and nature. Nor is the scene so confined here as at other parts, for from this elevated position a broad expanse of turf and water comes into view, the hills forming an appropriate background in the distance.

From the end of this fine promenade a walk leads inside the walls to Lady Shrewsbury's private flower gardens, of which there are two, one on each side of a splendid conservatory. The conservatory is about 60 feet long by 15 feet wide, and has a central transept. It connects the north part of the Towers with the south. At the south end a flight of steps leads up to the vestibule, from which the doors open into the flower gardens on either side.

Around the cornice of the vestibule is painted the motto—

"The speech of flowers exceeds all flowers of speech;"

while on that of the conservatory is another equally appropriate—"Consider the Lilies of the field how they grow; they toil not, neither do they spin, yet I say unto you that even Solomon in all his glory was not arrayed like one of these."

The fine collection of plants, arranged with much taste and skill, were worthy of the building they adorned. Some plants of the pretty *Rivina humilis* with their long clusters of bright red berries were very attractive, as were some magnificent pyramidal plants of *Pelargonium*, growing in wooden boxes neatly faced with bark. A fine *Cyathus medullaris*, and an equally fine *Dicksonia antarctica*, on opposite sides of the central pathway, were singularly well placed to give relief to the flowering plants. A variety of Palms were equally effective in the same way. A striking and beautiful effect was produced by covering long circular blocks of wood with moss, in which were revelling in the rudest health a charming mixture of *Iresine Herbstii*, *Panicum variegatum*, and *Selaginella denticulata*. Out of the tops of these little pillars sprang single plants of *Woodwardia radicans* and *Lomaria gibba*, thus imparting a grace and finish. I have endeavoured to describe fully

these very suitable objects for conservatory decoration, as I think them worthy of imitation. Another singular feature was two pretty arbours, one on each side, very ingeniously formed by placing a deal box filled with soil at each end of a seat, over which a broad arch of wirework is fixed; both the arches were tastefully covered with *Cobaea scandens* and *Tropaeolum Triumphantiae* de Gand. The sides of the boxes, forming the sides of the arbours, as well as those of many others placed in dif-

7.—The Pagoda.

Fig. 8.—Ruins Alton Castle.

ferent parts of the conservatory, were faced with cork bark, its rugged surface causing it to form a very suitable material for such a purpose. This is another idea of Mr. Rabone's which

is quite worthy of imitation. Many of the hanging baskets contained fine masses of *Panicum* and *Iresine*: this appeared to be a favourite mixture, and certainly no two plants more suitable for such a purpose could be chosen.

Looking along the building from either end the view is one of surpassing loveliness; and although I did not see it lighted up at night, yet I could quite appreciate the truth of the remark made to me, that when so seen it was a real fairy land.

I had not time for more than a passing glance into the other glass houses near the principal kitchen garden. In the first, a span-roofed house, were a large number of medium-sized plants of *Eucharis amazonica*, admirably adapted for decorative purposes, numerous fine *Caladiums*, a good *Vanda odorata*, a *Saccolabium Blumei majus* with a fine spike of bloom, a fine plant of *Acridea suavissimum* in flower, a fine stock of *Calanthe Veitchii* and *lutea*, and many other choice *Orchids*. Some *Alocasias* and a fine plant of *Caladium magnificum* were also noteworthy.

In another house were fine plants of *Pandanus elegantissimus* with graceful, pendent leaves, *Cibotium princeps* and *Schiedei*, a beautiful *Dasylyrium*, and a *Musa* bearing a splendid cluster of fruit.

The *Cattleya* house contained a large collection of *Orchids*, very healthy and flourishing.

I must not conclude these notes without noticing the flag tower, a massive square building of six storeys, finely situated a short distance from the principal block of buildings. From the top of this lofty tower a magnificent view of the surrounding country for many miles well repays one for the somewhat arduous task of climbing so high. Far and wide can the eye range from here over the broad domains of Alton Towers, along the beautiful valley of the Churnet, away into the vast undulating expanse of country beyond. But in all this pleasant landscape no object possesses so much interest as the ruins of Alton Castle (*fig. 8*), taking us back to those old feudal days when the baron exercised a despotic sway over the country commanded by his castle—those quaint rude times when might made right. What stirring warlike scenes must have occurred where now those few old grey stones bear silent witness of the lapse of time and the decay to which all things are hastening! And as one turns from contemplating them to look once more at Alton Towers standing in all the pride and dignity of their massive strength and grandeur, it seems scarcely possible to realise the fact that these old ruins represent what was probably at one time a structure equally stately and of far greater strength.

In bidding farewell to Alton Towers I may very safely promise any of your readers whom these notes may induce to visit them, that they will find a "land of delights," a scene of loveliness surpassing what they may be led to expect, for it is hardly possible in a report of such extensive grounds to notice more than the most important points of interest.—EDWARD LUCKHURST, *Old Lands, Buxted, Sussex.*

GARDENING AT THE ANTIPODES.

STRANGE are the queries that come to us, but none that we are not pleased to receive. It is a luxury to aid anyone. It gratifies one's vanity to be consulted, as if we were "wise ones," therefore we are really doubly gratified in being able to reply authentically to the following:—

"Gentlemen, Editors—I have been engaged to be married five years to W— R—, gardener to our clergyman, and he now insists on our marriage because he has an offer of a situation in Australia, and intends going there. I have not declined out-and-out, but yet do not know what to do. I see your gardening paper on master's table every Friday, and as I see you answer inquiries about almost everything, even Blackberry wine, perhaps you would be so very kind as to say whether Victoria, in Australia, is a safe place to live in. Are there any cannibals there? Are things there anything like what they are here in Wiltshire?"

We are tempted to state our confiding correspondent's name in full, to tell who is her swain, and who is her master. We are so tempted because we should like all connected with her to appreciate her as we do, and we know we are right. We have seen her handwriting, and, like Shenstone, "judge thence of her disposition;" but we forbear, and assure her that Victoria is a place safe to live in, that there are no cannibals to fear there, and as best evidence that it is "anything like Wiltshire," we print this extract from the "Report of the Horticultural Society of Victoria for the year ending June 30th, 1870."

In return for so doing, when she, as Mrs. R—, has reached Victoria we shall confide in her reminding her husband to send us a few notes on the Victoria gardening.

"The following catalogue is a list of varieties of fruit tree scions available this year (1870) for distribution among subscribers.

"Those in small capitals are supposed to be merely *colonia* terms, and are given as the received names of varieties in extensive cultivation throughout the Australian colonies.

"APPLES.—*Mela Carla* (Charles Apple), Kerry Pippin, Gloria Mundi, Api (Lady Apple), Whatmough's Red Streak, Duchess of Oldenburgh, Kishock Pearmain, SCARLET GOLDEN PIPPIN, Maiden's Blush (American), Boston Russet, Reinette Rouge Hative, Dumelow's Seedling, Pitmaston Golden Pippin, Lodgement Nonpareil, Uellner's Golden Reinette, Red or Devonshire Quarrenden, Pine Golden Pippin, Irish Peach (Early Crofton), Brownlee's Russet, Taliesin (Norfolk Beeding), White Nonpareil, Reinette Jaune Hative, Spring Ribston Pippin, Stamford Pippin, Omar Pasha, Summer Queen, Summer Rose, Hawley, Screevton Golden Pippin, Pitmaston Nonpareil, Betty Geeson, Forge Apple, Cornish Aromatic, Summer Golden Pippin, Oslin, American Mother, Guernsey Pippin, Isle of White Pippin, White Winter Calville, Wyker Pippin, Tyler's Cromwell Pippin. BOX APPLE, Golden Reinette, King of Pippins, Court-Pendu-Plat, Winter Peach, Keswick Codlin, Golden Nonpareil, Hawthornden, Downton Pippin, Warner's King, Pine Apple Russet, Tower of Glamis, Cox's Orange Pippin, Tam Montgomerie, Early Nonpareil, Early Almond, CHARLTON PIPPIN, Wyken Pippin, Early Joe, Ribston Pippin, REN CLUSTER, Scarlet Nonpareil, Alfriston, PORT DALRYMPLE, Kirke's Golden Pippin, Byson Wood Russet, HOARY MORNING, Winter Peach, Wormsley Pippin, Beauty of Kent, American Cherry Crab, New Rock Pippin, Bedfordshire Founndling, GOVERNOR GLADE'S RED STREAK, Yellow Siberian Crab, Stone or Gogar Pippin, Rhode Island Greening, KINGSTON NONPAREIL, Pigeonette, Pearl Reinette, Phillip's Seedling, H.S.V., Claygate Pearmain, DINON'S EMPEROR, Watson's Dimpling, CLEOPATRA, Gloucester Pippin, CAERMARTHEN PIPPIN, White Astrachan, KINGSTON BLACK, Pomme de Neige, London or Five Crown Pippin, Murray's Hawthornden, Yellow Bellefleur, Franklin's Golden Pippin, English Golden Pippin, Blenheim Pippin, King of Pippins, Cornish Gilliflowr, La Sonnette, Herefordshire Pearmain, Spring Grove Codlin.

"PEARS.—*Passe Colmar*, Summer Bon Chrétien, Late Crawford, Old Colmar, Duchesse d'Angoulême, Brown Bourré, Citron des Carmes, Chinese Pear, Paradis d'Automne, Marie Louise, Nouveau Poiteau, Bishop's Thumb, Old Bergamot, Comte de Flandres, Benrre Thérèse, Fondante d'Automne, Chaumontel, Thompson's, Leon le Clerc (Van Mons), Prévost (Van Mons), Comte de Lamy, Baron de Mello, Van de Weyer Bates, Gansel's Bergamot, Summer Benrre d'Arenberg, Colmar d'Ete, Fondante des Charnaux, Doyenné Defais, Doyenné d'Ete, Benrre Clairgean, Huysbe's Victoria, Early Crawford, Surpasse Crassane, Black Achan, La Quintinie, Napoleon Savinien, Marie Louise d'Uccle, Duchesse d'Orléans, Madame Trevey, Peach Pear."

Of Grapes there are the Black Hamburgh, Muscat of Alexandria, and most of the varieties grown in England, besides many vineyard kinds. Of Cherries twenty-five sorts are enumerated, of Plums about the same number, of Strawberries two score, besides several kinds of Medlars, Peaches, Nectarines, and Apricots.

WOOLHOPE NATURALISTS' FIELD CLUB.

OCTOBER 6TH.

THE FORAY AMONG THE FUNGUSES.

THE autumnal meeting of the Woolhope Club is generally spirited and successful. It is the last of the year, and perhaps greater effort is made to attend it, and certainly the well-wooded scenery of Herefordshire never looks more beautiful than on a fine autumnal day, but the chief cause of attraction undoubtedly exists in the opportunity it affords for the study of Funguses. This is made the chief object of the day, and no effort is spared to render it as instructive as possible to all who attend. The specimens found are at once named, or if perchance they are new, or present any features of particular interest, they are discussed with a scientific zeal that cannot fail to impart itself more or less to all who are present. Thus more real practical progress in the knowledge of this difficult branch of botany is made in a single field-day with the Woolhope Club than could possibly be gained by any amount of mere closet study.

The long and lovely summer followed, as it has been thus far, by a dry and bright autumn, has so completely dried the surface of the ground that vegetation of all kinds languishes for moisture. Notwithstanding the great want of rain, the mists and the dew have occasionally been very heavy, and, where the ground is rich and not too hard, have favoured very much the production of Funguses. It is true that they who would gather them in perfection this year must not heed the poet's caution:

"The dews of the morning be careful to shun,
They're the tears of the night for the loss of the sun."

The members of the Club had certainly not shown much fear in this

direction, for the baskets of Funguses they brought with them proved that many a successful foray had previously been made. In addition to these a large hamper had been kindly sent from Whitfield. Holme Lacy and Haywood Forest supplied the Vegetable Beefsteaks, and Mr. Worthington G. Smith most thoughtfully brought down a selection of the Funguses with which he had won the prize the day before at the Royal Horticultural Show at South Kensington.

The great success of the exhibition of Funguses was thus assured, and while several gentlemen most diligently occupied themselves in writing their names and arranging them on the tables provided, the rest, with Elmes Y. Steele, Esq., in the chair, proceeded to transact the ordinary routine business of the meeting.

The members of the Caradoc Field Club had been invited to join in the day's proceedings, and were represented in the field by the Rev. E. Donald Carr, the Honorary Secretary, the Rev. J. D. La Touche, and several other gentlemen. In their honour the special district from which the club takes its name was to be visited, and the road was first taken for Hagley Park, about four miles east of the city. Here they were kindly welcomed by Arthur Hutchinson, Esq., and proceeded at once to examine the quarry which has so special an interest for the members of the Woolhope Club.

Minute and careful as were the researches of the officers of the Ordnance Survey in this district, the existence of an upheaval of Silurian rocks at Hagley Park entirely escaped their notice. The discovery of this quarry in which they are so manifestly shown was the first feather in the cap of the Woolhope Club. It was made by the late M. J. Scobie, Esq., who worked at it with all the intelligent zeal for which he was so distinguished. He took the exact dip of the strata, noted their characters, measured their thickness, and collected their fossils, until he had quite satisfied himself with the reality and importance of his discovery. He then invited the late Hugh E. Strickland, Esq., F.R.S., F.G.S., reader in geology at Oxford, to come and see it. Mr. Strickland fully confirmed Mr. Scobie's observations, and wrote a paper on the subject, which appeared in the Quarterly Journal of the Geological Society.

The general facts and conclusions of this paper were given to the gentlemen present, with an account of the erustacean fossil found here by Mr. Scobie. It proved to be the *Pterygotus problematicus* of Agassiz, and it was afterwards figured and described in the Quarterly Geological Journal of J. W. Salter, Esq., F.G.S.

It was decided that these papers of Messrs. Strickland and Salter should appear in our own Transactions—meanwhile an active examination of the rocks was being made and many fossils were found. This celebrated "Ludlow Bone bed," described by Sir Roderick Murchison in the "Silurian System," is unquestionably represented in this quarry. It occurs between the Downton Sandstone and the Upper Ludlow Shale, and varies here in thickness from that of a wafer to 1½ inch in some places. The quarry was not being worked near the junction at this time, but a search was made specially for it, and with the aid of a man and a pickaxe some few spines were found on October 6th.

The Rev. J. D. La Touche said this bone bed varied very much in thickness in different localities, as might be expected. At Corston, Salop, it was as much as 6 inches in thickness, and consisted almost entirely of a mass of scales and teeth and bones of fishes broken up and waterworn—what these fishes were is not known with any certainty.

Leaving the quarry the hunt for Funguses beneath the Oak trees in the park began most unsuccessfully—not one was to be seen; but here, as everywhere else, the abundance of acorns could not fail to be observed, and the wonder was expressed why they were not systematically collected. When crushed and given in small quantities to sheep and pigs, acorns form a most nourishing and useful food. At a time when fodder is so scarce as it is this year, it does indeed seem strange that this prolific source of food should be so much overlooked. The Horse Chestnuts, too, are still more neglected, and yet it is stated positively, that when crushed, cows will eat them readily and give an increased supply of excellent milk. This year they, too, are very abundant and fine, and it is said that their only use should be as playthings for children to string and hang round their necks. Will no one give village children the delight of collecting them for some small recompense, make experiments with them in feeding cattle and horses, and publish the results? As a scientific society, the Woolhope Club can say they are certainly not poisonous, and equally sure is it that they are nutritious, but whether the animals could really be got to relish them, and if so the best way of inducing them to do so, are points that have yet to be discovered.

Two fine Lombardy Poplars grow in Hagley Park. They are believed to be the largest and tallest in the county. At 5 feet from the ground they measure respectively 12 feet 10 inches and 14 feet 1 inch in circumference. They stand out boldly all alone, and spread out their boughs in a way that conceals their height, and yet the tallest by shadow measurement was made 132 feet high. Each tree sends out from its bole strong buttresses towards the north, the latter to resist the winds they are exposed to.

At the foot of one of these trees some fine Funguses were found. They were thought to be *Agaricus* (*Phohota*) *pedunculatus*, and from their fragrant smell and pleasant taste, which many tried, were also judged to be edible. On reference to the best authorities both surmises proved to be correct.

Some 50 yards from one of the Poplars stands the Hagley Park

Elm, and this grand tree was next visited. It has still a fine upright bole, almost free from the excrescences to which Elms are so liable. It gives in fair measurement, 22 feet 10 inches in circumference at 5 feet from the ground. It is long past its prime, has lost its top and many boughs, and is partially hollow, but it is still a noble well-balanced tree. It was greatly admired, and the wish several times expressed that it might be photographed for the Transactions. In the same field another luxuriant Elm gives a circumference of 14 feet, and thus adds its testimony to the richness and strength of the soil below.

Near the east entrance at the cross road stands an Elm which figures as a boundary tree on a map of the estate with the date 1731 upon it. Its girth is only 11 feet 9 inches, and it is given simply as a notable tree.

The celebrated trap dyke at Bartestree was the next object on the programme. The fine high pasture field leading to it was searched in vain for the Funguses, which must commonly grow there, nor did it today give the pleasure it usually does to its visitors, for a mist hung over the scene, and rendered but dimly visible the well-known clump of Fir trees on the summit of Blackbury Hill, which had yet to be surmounted.

The geologists were interested, as they ever must be, with the well-known dyke of greenstone at Bartestree. It has been thrown up in a fissure a few yards wide, through horizontal strata of old red sandstone, and by its intense heat at the time has baked the sandstone into a dark friable mass. It has now nearly all of it been quarried away for road-mending purposes. The remainder should certainly be left as an object of the deepest scientific interest.

On leaving this remarkable basaltic dyke, a lofty and most luxuriant bramble bush, hung with sable fruit more than usually fine, attracted attention. It was a striking and uncommon variety, but happily the highest authority for this puzzling genus was present, and on being appealed to, Mr. Lees pronounced it to be *Rubus radiis*.

The way was then taken for the high road, but a very interesting halt was called in the corner of a Barley stable field, just below the convent. Beneath the drop of a hedgegown Oak some Funguses were found of a very peculiar character. They were judged at first to be the *Scleroderma vulgare*, with its usual centre of dark blue sporules, opening in a peculiar stellate way in consequence of the dry weather. Mr. Broome, however, at once remarked that the stellate markings were visible on the immature Funguses, and he pronounced it to be *Scleroderma gaster* of Fries, which we may call the Star-like *Scleroderma*. This variety, though often looked for, has never before been found in Britain, and thus a marked addition to British Fungology has once again been made by the Woolhope Club.

The carriages were again taken at the Longworth entrance lodge for the foot of Blackbury Hill. At the Priors Court Farm they were left, and the ascent of the hill commenced through the dense covert which clothes its sides, all beautifully variegated as it was by the touch of autumn. Amongst

"The tints of rich and roscate hant,"

the leaves of the wild Gaelder Rose, *Viburnum Lantana*, here at home upon limestone, and the almost bloody hue of the Spindle tree, *Euonymus europæus*, were eminently conspicuous, contrasted as they were with the pale orange of the Maple, and the varying hues of the fading leaves around them.

Blackbury Hill has several botanical productions of interest, among which the Green Hellebore, *Helleborus viridis*, may be noted, while the masses of Virgin's-bower, *Clematis Vitalba*, flourish with such graceful exuberance as to arrest attention at every step.

The hill is formed by the Aymestrey limestone, which at the summit is broken up into great masses of exposed rock, with such deep cavities and passages interposed between them as to suggest some violent cataclysm having taken place on the spot, rather than that slow wearing away by the tooth of time, as was contended for by the Rev. J. D. La Touche. Traces of violence here seemed evident, though whether by the gunpowder of man in blasting the limestone of the quarry or the earthquake's titanic effort in ages past, there is no record to show. There is a very interesting camp on the summit, with a double entrenchment towards the east, and a covered way, which may not now be dwelt upon. The exposed precipitous masses of fractured rock are commonly called "Adam's Rocks," or sometimes "Hatton's Rocks," but from what circumstance the name is derived, whether legendary or historical, is not known. Whether some glorious old chieftain of that ilk held the camp successfully against all comers, or whether some inglorious rascally Adam, or Hatton, may have broken his neck here on a misty November eve, there is no certain information forthcoming. Be this as it may, the visitor to this spot, whether of a geological or poetical turn of mind (though he must be careful how he turns his body), will be charmed with the prospect before him; the coloured woods, the verdant dales, the holdly rising hills, the distant views stretching on beyond the curvatures of the sparkling Wye to the Black Mountains, bounding the horizon, may not readily be forgotten when once they have been seen. On the present occasion, however, the break of sunshine had unfortunately disappeared, and a tantalising brooding mist,

Like sorrow's veil on beauty's brow,

as Anacreon Moore writes of a like, "Mist o'er blooming bowers," about famed Killarney, now hid the distant prospect, and even dimmed the celebrated Haugh Wood, the dome from which the other rocks of the Woolhope Valley are thrown off subordinately.

The company were here assembled by the sound of the whistle, and

having accommodated themselves to the inequalities of the ground. at the request of Dr. Bull the Rev. P. B. Brodie, M.A., F.G.S., gave a very interesting extempore lecture on the geological features of the Woolhope Valley before them, comparing the remarkable features of this district with the more extended one of the Wealden in Sussex.

In the course of this address Mr. Brodie mentioned that when working in the Woolhope district this spring, with his own Field Club, he had been so fortunate as to discover a small and very perfect specimen of *Eurypterus*, which he had sent for examination to Mr. Henry Woodward, of the British Museum. He had just had a letter from Mr. Woodward, in which he stated that it was a new species, and that he had named it the *Eurypterus Brodiei*, in honour of the finder. It was found at the Parton quarry, near Stoke Edith, and as it came so strictly within the province of the Woolhope Club, Mr. Brodie kindly offered it for illustration in the volume of Transactions, an offer which was very gladly accepted.

The order was now given to search for Funguses, but although the district was most favourable for them, beyond the large tufts of the ubiquitous *A. mollens* and *A. fascicularis* but little was found. Many small specimens of the orange *Chantarella*, *Cantharellus unrantiaeus*, were gathered; Mr. Houghton found the Fir-cone *Hydnum*, *Hydnum ariscalpium*, always so curious and interesting; Mr. Elmes Y. Steele got the graceful green *Agaric* with its silky veil and stem, *A. aruginosus*; several of the *Myccena* tribe were also gathered, as *A. polygrammus*, *A. alcalinus*, with one or two near allies, *A. epipterygia* amongst them. These are sufficient to show how many more there would have been under more favourable circumstances. The drought was too prevalent, and *Agarics* could only be numbered by noits instead of by scores, as fondly hoped for, but as a popular poet has said—

"We may roam through this world like a child at a feast,
Who but sips at a sweet and then flies to the rest;
And when pleasure begins to grow dull in the east,
We may order our wings and be off to the west."

And so on the present occasion the disappointed fungologists drew off from the wood to the open ground on the shoulder of the hill, and visited the two stunted Hawthorns, so oddly called "the Cow and Calf." The view from this spot is usually most extensive and beautiful, but at this time it was enshrouded in mist, and since the Funguses were again absent the descent was made to Old Sinton, where the carriages were waiting to convey the visitors to Hereford.

The ride home would have been very pleasant but for the myriads of aphides which swarmed in the air. It would almost seem true that

"The thin-winged flies their transient time employ,
Reeling through snubbeams in a dance of joy."

The Turnip aphid, however, has been terribly destructive this autumn, and a field on the hill was passed smelling horribly from the decaying bulbs of the Turnip plants they had destroyed.

An examination of the Funguses, at the Green Dragon, brought for exhibition passed the time remaining before dinner very pleasantly. It was an extremely interesting collection, and the only wonder was that in so dry a season so many could have been produced.

The most striking specimens were the arborescent Funguses, as might have been anticipated. A huge specimen of *Polyporus frondosus* was placed in the centre of the table, and undoubtedly carried off the palm both for interest and novelty. It weighed no less than 14 lbs., and from its great size, the beauty of its lines, and its gracefully overlapping pilei, it proved the chief attraction in the room. This species may be said to be virtually new to Britain, for although its presence has been more than suspected by several botanists, it is not given as British in any of our flora, not excepting Mr. Cooke's recent handbook. It is true that Mr. Berkeley published a species under this name in the English flora, but he afterwards corrected himself and referred his former plant to *P. intybaceus*, leaving out *P. frondosus* altogether. A specimen of *P. frondosus*, gathered at Whitfield, was sent by Dr. Bull to the exhibition at South Kensington; and, besides the grand one brought to this meeting by J. E. Smith, Esq., from near Hay, there was another from Whitfield, and also a very fine one brought by the Rev. W. Houghton from the Wrekin. We have now, undoubtedly, in England all the three species of Fries:—*Polyporus frondosus*, known in addition to other characters by its pore-surface and its flesh turning grey when bruised; *P. intybaceus*, with its hundreds of pilei tufted together, very much branched, and smelling like mice; and the *P. giganteus*, with its large imbricated pilei, turning red when bruised, and smelling horribly like rotten cheese.

There were also very fine specimens of *Polyporus applanatus* and *P. hispidus*, with *P. rufescens*, *P. fumosus*, *P. varius*, *P. annosus*, and the ever-present *P. squamosus*.

The next Fungus which created much interest was a fine specimen of the edible *Sparassis crispa*, brought by the Rev. W. Houghton from the Wrekin. It was the size of a Cauliflower, of a bright orange colour, and very pleasant fragrant odour. It is very rare, but has been found this year in several localities, as attested by the Rev. M. J. Berkeley and C. E. Broome, Esq.

Two fine sturdy specimens of *A. corticatus* were exhibited. They were found growing on a Beech tree, and possessed considerable interest, as well for their great beauty as for the great rarity of their occurrence in this country. *Agaricus porrigens*, a beautiful snowy white *Pleurotus* of great rarity and beauty, peculiar to fallen Pines, was sent from the Duke of Argyll's plantations at Inverary. The rare *Cortinarius fulgens* was there also; *Lactarius deliciosus*, rufus,

tormentosus, *vellereus*, and *controversus*; *Russula rubra*, *fragilis*, *lepidia*, and *ulmata*; *Boletus luridus*, *edulis*, and *versipellus*; the *Agaricus Cecilia*, *procerus*, *rufescens*, *maculatus*, *rutilans*, *squarrosus*, *rimosus*, *nudus*, *tuberosus*, *gallinaceus*, *butyraceus*, *lacrymans*, *infundibuliformis*, &c.; *Pistulina hepatica*, *Paxillus involutus*, *Hydnum udum*, *H. repandum*, *Helotium vergulatum*, &c.

A very puzzling lot of sulphur-coloured *Agarics* was brought by Mr. Houghton, which seemed to agree with no known group. They were, however, provisionally referred to the rare *A. (Flammula) inopus* of Bolton, or perhaps *A. hybridus* of Fries.

A great variety of common *Agarics*, which it is unnecessary to mention, were conspicuous by their absence.

There was some little difficulty in procuring sufficient edible Funguses for the dinner, but the following dishes were sent round with more or less satisfaction:—*Pistulina hepatica* fried, and finished in its own gravy; *A. deliciosus* stewed; *A. procerus* and *A. rufescens* broiled. The novelty of such dishes is now over with the Woolhope Club, and it becomes difficult to take the opinion upon them. *Procerus* was most asked for again, and may be supposed, therefore, to take the place of honour.

After dinner the President called upon Edwin Lees, Esq., F.L.S., &c., to read his paper "On some curious *Agaric*, only apparent in times of drought, with notices of those that occur and colour water at seasons of high temperature," and Dr. Trimen, of the British Museum, made some remarks upon it.

The following papers were also read:—"The Fungi which affect our Forest Trees," by Worthington G. Smith, Esq., F.L.S.; "Notes on Fairy Rings," by Jas. Buckman, Esq., F.L.S., &c.; and "Illustrations on the Edible Funguses of Herefordshire," by Dr. Ball. These papers, with such discussion as they elicited, will be published in full, and it only remains now for us to say that they were of high interest, and gave much entertainment to the members present.

NOTES AND GLEANINGS

ROYAL HORTICULTURAL SOCIETY'S COMMITTEES.—The next meetings of the Fruit and Floral Committees are to be held on November 2nd, and December 7th; and not November 16th, and December 21st, as previously announced in some of the early issues of the schedule and almanac.

—AMERICAN WINTER GARDEN.—*Nature* announces that the United States Congress has granted 30 000 dols. for the erection of a Government Winter Garden, either at New York or Washington, somewhat similar to that at Kew, but on a smaller scale. This will partake partly of the nature of an economic garden, in which useful plants can be raised and then disseminated far and wide throughout the States.

—CINCHONA CULTIVATION has so well succeeded in the English hill settlement at Darjeeling, in the Himalayas, that last year 5000 lbs. of bark were sent to London from Cinchona trees planted in 1862, on one plantation. Tea produced, in 1869, 1,319,713 lbs. from 10,769 acres of hill land formerly said and reputed to be worthless, and unsuited to give a return to Englishmen. We shall now hear of Indian bark as well as Peruvian, as we know Indian Tea to hold its own against Chinese. The Cinchona trees are also taking well in Jamaica. Experiments on the culture of American Tobacco in India are being made by the Maharajah of Burchwan, in Midnapore and Cuttack. The last year's experiments with seeds from James River, Virginia, were very successful.—(*Nature*.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

THIS is an excellent period for laying down the spring *Broccoli*. It is best performed by two persons, one at each side of the row. Keep a good trench, and sink all the heads to the north, hurrying the stems in soil up to, and even amongst, some of the lower leaves. This proceeding will protect the heads very considerably against a severe winter—first, by reason of the position; secondly, by avoiding sudden changes or excitement; and thirdly, by the reduction of succulence. Pull *Cauliflowers* before they grow too large, and prepare a shed or pit in which to plant a quantity on the first approach of frost. *Dwarf Kidney Beans*, remove those growing in pots to where they can have the protection of glass. It is no uncommon or new practice for good kitchen gardeners to throw their overgrown *Lettuce* or *Cauliflower* plants on the ground to shrivel before planting them. Plants in this state will endure hard weather better than those in luxuriant growth. Remove the leaves from *Rhubarb* and *Sea-kale* that you intend forcing very early, and keep a look-out for slugs and weeds.

FRUIT GARDEN.

Pay every attention to getting the wood of Peaches and

Apricots well ripened by exposure, shortening, &c. Put the ground in order for planting all kinds of fruit trees. On cold stiff soils it is advisable to plant on hillocks 1 foot or 18 inches higher than the surrounding surface. The trees will not grow so fast in consequence, and will require more attention in summer in the way of mulching, but they will form short-jointed, well-ripened, fruitful wood, which is the best preventive of canker, gum, &c., and will save the labour of resorting much to root-pruning.

FLOWER GARDEN.

I would urge the necessity of taking advantage of the first favourable opportunity to plant the main bed of Talips; every week that they remain unplanted will be prejudicial to them, though I make no doubt many will put off planting till the middle of November. All bulbs which have been reduced in size should be removed from the position they hold in the best bed, and be planted in a side bed to recover their strength previous to being reintroduced, and their place should be occupied, if possible, by some other variety which will nearly correspond with that taken away. The amateur must ever keep in mind the necessity of preserving the uniformity of his collection. After another week or ten days I would advise no one to remove Carnations: it will then be late for them, and it is so important they should be well established previous to the coming winter, that no time should be lost. Auriculas must be carefully preserved from heavy rain, and a watchful eye kept on the surface of the pots, which will speedily indicate where the drainage is bad. As the winter approaches protection of some kind should be provided for plants and shrubs of tender character; almost any material is eligible, provided it will in a considerable degree throw off wet. Canopies for this purpose should be so contrived as to admit of one or two sides being opened at pleasure; if only one, it is advisable to place it on the north or west side, certainly not on the south side, as the excitement caused by bursts of sunshine is apt to prove very prejudicial. The covering or canopy should by no means be allowed to touch the plant, and the greater the space allowed between it and the plant the better will it afford protection. It is a bad practice to bundle the shoots together like a besom, in order to make them occupy a more limited space; doing so may save trouble and material, but is a most injurious proceeding. More injury is occasioned by confined damp in a majority of cases than by lowness of temperature. Hoodings of straw, so formed as to overlap the protecting material beneath, are very good and simple protectors, and, if rightly contrived, may be removed with as much facility for ventilation as the top of an ordinary hand-glass. Oilcloth will also form a good protection if made into a kind of cone, on the sides of which a small flap or two may be made to open without admitting the rain. Before the application of any top covering, it is advisable that an inch or two of the surface soil around the collar be removed, and replaced with dry sawdust, the newer the better. This should be piled as high as the stem of the plant will admit, taking care not to choke too many of the lower leaves; and if the canopy is so contrived as to overlap the mound, the covering will be complete. The only thing that remains is to give air at favourable opportunities, avoiding cutting winds, which in all probability do more harm than the frost.

GREENHOUSE AND CONSERVATORY.

Proceed according to former directions; see that all plants belonging to the conservatory are housed forthwith. Do not be flattered by fine weather, such as at this period usually flatters to betray; cleanliness, free ventilation, and clever arrangement, are the main points. If severe weather should occur do not hesitate to use a little fire heat at times, especially where many plants are blooming, as by these means a free ventilation may be indulged in to expel damp and stagnant air. A mere hibernatory is another thing; in this, whether the roof be of glass or opaque, free ventilation will be all that is requisite for some time to come. By means of Roses, Chrysanthemums, and other late-flowering plants, this structure may yet be kept gay for many weeks. Supply them occasionally with manure water in a clear state. It should be administered about 5° or 10° warmer than the atmosphere of the house. If the water is just coloured it will be sufficient. An ounce of ginseng with a handful or two of soot will make a large bucketful or canful strong enough for anything, and it ought to be provided as clear as fine ale. Damp and mildew are the great enemies to be guarded against at present in conservatories and greenhouses, and these must be sharply looked after, especially in the case of plants that have not ripened their growth, and are in a rather soft state.

If damp is troublesome it must be dispelled by means of free ventilation in mild days, using a little fire heat at the same time, and for mildew a dry airy atmosphere is the best preventive; but the plants should be frequently examined, applying sulphur on the first appearance of the evil. Very little water will be required at present, but the plants should be carefully looked over about twice a-week to make sure that nothing is allowed to feel the want of it. If not already done get plants tied into proper form with the least possible delay, for it is difficult to tie a plant so that it will not look somewhat stiff and unnatural, and the sooner all this kind of work is done the better the specimens will look when in bloom.

STOVE.

Much less moisture will suffice at this period, even for the growing Orchids; keep the temperature progressively on the decline, more especially in dark weather. Ventilate freely whenever the weather will permit.

COLD PITS AND FRAMES.

Cold pits will now be in request. Sawdust forms a good plunging material, if new and dry; coal ashes are also very good. Whatever material is employed, keep the plants within a foot or so of the glass, and endeavour to keep the soil in a somewhat dry state. A portion of the stock of Roses, Lilacs, Honey-suckles, &c., in pots, may soon be placed in a pit to have a slight advance of temperature. The present is a good time to procure from the nurseries or the reserve garden a supply of Rhododendrons, Azaleas, and Kalmias, for forcing. Select plants well set with bloom, and of the desired size. Some of the hybrid scarlet Rhododendrons, as Nobleanum, and others, require but little forcing, and are the best to start first. Place them in as small pots as their roots can be got into without injury, and set them out of the reach of frost till wanted. Abundance of air and light must be admitted to these structures. If any of the lights afford a partial shade to the plants from the accumulation of dirt, take them off and wash them thoroughly without delay. Be careful to supply water only to plants that require it. Remove all mouldy and decaying leaves, and keep the interior as dry as possible during dull foggy weather. If you discover the unwelcome presence of the green fly upon your plants fumigate them with tobacco, which will put an end to them for this season. All half-hardy plants which it is desirable to secure for next season, may be potted with balls and wintered in these structures.—W. KEANE.

DOINGS OF THE LAST WEEK.

THE rains came as we expected, and though not in the deluges spoken of in other places, yet in sufficient quantity to give us water for some time to come. More trying, perhaps, than the rains were the frosty mornings and the hurricane of the 12th, which tried many trees and shrubs, and did a little injury among our glass, though we thought all was securely fastened. The heavy showers, the wind, and even the frost have left the flower gardens still passable on this the 15th inst., except some fine beds of Coleus, from which the leaves are dropping. The Iresine is still quite fresh, and the Heliotrope is only slightly marked in places. But for the lashing of the wind and rain Calceolarias would still be fine, and scarlet Geraniums are very passable, showing a good deal of bloom, though even Cabbage leaves on some mornings were quite hard with the frost. The frost and the rains together have done more than all our care to eradicate the legions of Cabbage fly, that but for being warred with would have carried all before them. It is sad to hear of the wrecks they have left in many places. We may also add that Vegetable Marrows have had their leaves considerably blackened by the frost.

KITCHEN GARDEN.

The work was much the same as last week, and chiefly consisted in earthing-up Celery when fine, pricking-out Lettuces, blanching Lettuces and Endive, taking up Carrots, Parsnips, &c., and preparing for the first Cauliflowers of spring by giving a little fresh lime to the ground to drive away the slimy tribe and make the ground more mellow, and the old organic material in the soil more sweet and soluble. There is hardly an old kitchen garden that a moderate *lime-dressing* would not improve. If the soil were light it would make it more retentive of moisture. If stiff and heavy, it would make it more mellow and open; and though, looked at as manure, it will do little good on poor land, it will increase the fertility of all soils

that, like kitchen gardens in general, have been well supplied with manure.

FRUIT GARDEN.

Most of the hardy fruit is now gathered, though a few of the latest will be housed the first bright dry day, as they will not do much more good now, though late Apples and Pears swelled freely recently. Looked over the fruit room to keep all sound, and gave a little air to allow the sweating to escape. Peaches on the walls have been over for some time, and the last in the orchard house are now nearly over. There are a good many Plums still, and, with proper arrangement, in a late Plum house we believe they could be had in fine order a month or six weeks later than it would be possible to have them out of doors on walls. Grapes in another orchard house have ripened well, but that is not much in such a season as this, when in many places not only in the south, but considerably north of London, they have ripened well out of doors. We took the lights off the Peach house, not so much for exposing the trees thoroughly, as to get the lights themselves thoroughly cleaned and renovated. The trees and house will be effectually cleaned before they are replaced, as red spider made its appearance after the fruit was gathered.

The Strawberry plants for forcing which we could get rather late, are making rather large leaves for our taste, and by turning the pots on their sides in wet days we must try to have the fine buds well ripened. A number of the most forward we have put on the north side of walls, &c., to give them a rest before starting them afresh. Melons are now nearly over, and the places occupied by them will come in most useful. In fact, room is now so valuable that every house as it gets empty of fruit must be cleared and filled temporarily with plants. An earth pit sown with Kidney Beans in July, is now giving fine returns with the help of protection at night.

ORNAMENTAL DEPARTMENT.

Similar notices to those lately made respecting fruit trees would hold good as to planting ornamental trees and shrubs, and trees and undergrowth for plantations and covers. After the rains these will soon lift and plant well even in this dry neighbourhood; and planted at the end of the month they will, whilst the ground is warm, have two chances to one of doing well as contrasted with planting in spring. In places where game is all in all, it is but labour and money thrown away, if no protection with wire netting be afforded; and for small rabbits the meshes of the netting must be very small—not more than $1\frac{1}{2}$ inch. Wherever a young rabbit can squeeze his head in flat he will manage to pass his body in afterwards, and then he will soon grow too big to get out at a similar opening, and the trees and bushes will form an irresistible attraction. We noticed lately a communication recommending sinking such netting in a little trench 1 or 2 inches below the ground level, so that the rabbits might feel the net when burrowing. We thought it a good plan at first, but soon found the rabbits cared nothing for this wire, going down easily, and as a matter of course beneath it. A far better, because a more perplexing plan to the rabbits, is the following:—Prepare yourself with stout pegs and stakes, the latter, after going firmly into the ground, to be as high as the width of the netting; unroll the netting and stretch it out, flatten down the side next you, which will be the outside of the fence, and pin down to the ground the netting, leaving from 1 to 2 inches on the level outside the hooked pins. Then begin at one end, and raise the netting straight and level, and fasten to near the top of the stake inside with a small wrought iron nail driven in obliquely against the wire. This is, perhaps, the most simple, secure, and effectual mode of fastening such netting, because based on the habit of the rabbit of beginning to burrow close to the upright fence. He thus comes in contact with the horizontal pinned-down part of the netting, and seldom has the philosophy to go further back and make a fresh trial.

Followed up what was lately recommended in taking under cover the most tender plants which were exposed. A few more Cinerarias had their largest leaves a little blackened by the frost. Proceeded with potting and moving, and as soon as some fruit houses are empty we shall thoroughly clean them, and then fill with Geraniums and bedding plants, where they will be secure for the worst, coldest, and darkest months of the year.

We have yet taken nothing up from the flower garden, but the small cuttings put in are doing well. For a particular reason we do not wish to break the outline of the beds and

borders until the end of the month, as the grass looks lovely, and the gale of the 12th has cleared away all the most forward deciduous leaves from trees, as well as all those that had fallen, taking them miles away into the fields, and leaving the lawns cleaner than if carefully swept. We only had to pick up some barrowloads where they had rested against flower beds and borders.

When a beautiful lawn has been disfigured in the autumn months by the fallen leaves of deciduous trees, we have often wished to have a flower garden where no leaves of deciduous trees could mar its beauty, but where the greenness of the Laurel, the Holly, and the Pine tribe, should contrast with and show off the beauty of the bright colours in the beds and borders. It so happens, however, that no one definite mode combines in itself every advantage, for if evergreens are thus beautiful at all times, and give little trouble in spring and autumn, they do give trouble by the dropping of their older leaves in summer, requiring much moving and sweeping up in the brightest days of the year.

Though we have taken up no Geraniums as yet, if we saw signs of a sharp frost we would lift some of the most tender, as the variegated kinds, and others of which we might be scarce, and place them under cover until we could arrange them properly. In the meantime it will be useful to mix tree leaves and short grass with long litter, so as to be able to give a little bottom heat to subjects we wish to root quickly.

As respects Geraniums in beds, we submit the following as hints to beginners who do not like the idea of the frost making wrecks of all their fine plants:—

As respects all Tricolored and merely Variegated Geraniums, they will do best, when taken up, if the larger leaves are all removed, leaving the smaller ones, shortening any very long roots, and cramming the rest of each plant into a small pot, plunging the pot in a mild bottom heat after watering it, and giving air at top except in severe frost. Such plants will soon make fresh roots, and they will do better if the plants, or rather the pots, stand on a dry board.

Where there are some fine-grown large plants of Geraniums, and it is desirable to keep them large, take away every leaf larger than a shilling or two-shilling piece, shorten the very longest roots, place the rest in the smallest pots that will contain the roots, plunge as stated above, and when rooted place the plants on a dry shelf. Success here, as regards large specimens next year, will depend on the shoots not being shortened, the axis of growth being kept sound, and having plenty of air, light, and heat to keep them slowly growing all the winter.

A third mode, more applicable for rough treatment, is to take up the plants, shorten all the shoots a little, remove every leaf, pack the roots closely and firmly into pots or boxes, so that the box or pot above the soil will look like a bundle of wood faggots; water, and when dryish on the surface, cover with dryish soil. These will thrive in any place from which frost is excluded, if cool enough not to encourage growth, but when the stems break about March, they must then have light in fine days, and in another month be thinned. These will make fine plants for the centres of beds in the following year.

A fourth plan to secure dwarf plants for next season, is to cut such plants down some 4 or 6 inches from the ground, remove every leaf, dip the points of the shoots in lime and charcoal dust, and treat roughly as above; in any place tolerably dry and free from frost, they will need little light even until the plants break afresh. We have known, however, many cases where some hundreds of such plants have been kept in little space all secure during the winter, in a spare room or a hayloft, and then all killed by exposure to a few hours' severe frost in March. Keeping in this rough way, and flowering well in future, depend on just keeping the plants alive, and not encouraging fresh growth at all. Wherever we have growth and fresh leaves, there must be light and air, as well as enough of heat to keep out frost.—R. F.

TRADE CATALOGUES RECEIVED.

André Leroy, Angers.—*Supplément au Catalogue de 1868. Prices of Fruit Trees and Ornamental Trees and Shrubs, 1870-71.*

J. Standish & Co., Royal Nursery, Ascot, Berks.—*Catalogue of New and Rare Plants, Hardy Trees, Shrubs, Conifers, &c.*

Charles Turner, Royal Nurseries, Slough.—*Catalogue of Roses, Fruit Trees, Conifers, &c.*

F. & A. Dickson & Sons, 106, Eastgate Street, and Upton Nurseries, Chester.—*Descriptive Catalogue of Roses and Hollyhocks.*

TO CORRESPONDENTS.

* * * We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By doing so they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

BOOKS (*An Amateur, Newcastle*).—"The Greenhouse," by C. McIntosh, and "In-door Gardening," by Keane. The latter you can have post-free from our office if you enclose twenty postage stamps with your address. (*Bayard*).—You probably mean "Paxton's Botanical Dictionary," a single volume, price 25s.

CHRYSANTHEMUM SHOWS (*J. P.*).—There will be some near London, and will be advertised.

SEEDLING PANSIÉS (*G. McD.*).—The blooms were all withered. We cannot prophesy what would be the result of advertising your Melon seed.

PAMPAS GRASS (*G. S.*).—A panicle of a female plant was enclosed by you. It is the usual colour. It is the male plant that bears the plumes.

RAINFALL (*J. B.*).—The differences are not at all extraordinary. We have seen rain falling on one side of a road whilst there was none falling on the other side.

MOVING ROSES (*J. H.*).—You may remove the Roses budded this year, but it is a good plan to let them have a year's growth before removal to their final quarters. If removed now they will not start strongly in the spring, but care being taken in moving, there is not after all any great difference.

SOWING THE SEEDS OF EVERGREENS (*Idem*).—The Laurel berries should be kept in sand, and in February be sown in sandy soil in a warm yet open situation. The Rhododendron seed should be sown in pans or boxes, or in a cold frame in March, in a compost of sandy peat, with a free admixture of silver sand. Keep the soil moist, and admit air freely, and when the plants appear draw down the lights. The present is a good time to plant Virginia Creeper and Clematis.

ANNUALS TO FLOWER IN A GREENHOUSE IN SPRING (*E. B.*).—Besides *Nemophila* and *Mignone*, you may sow now *Alyssum maritimum*, *Asperula azurea setosa*, *Calandrinia umbellata*, *Campanula Lorei*, *Clarkia pulchella* and *C. pulchella alba*, *Collinsia verna*, *C. bicolor*, *C. candidissima*, *Eucharidium grandiflorum*, *Gilia tricolor* varieties, *Gypsophila marialis*, *G. elegans*, *Kaulfussia amelloides*, *Leptostemon aureus*, *L. androsacens*, and var. *albus*, *Lupinus annuus*, *Nolana atriplicifolia*, *Platystemon scifloricus*, *Silene ruberrima*, *Viscaria oculata*, *Whitlavia grandiflora*, and its white variety.

WINTERING CANNAS (*Idem*).—Keep them in any place free from frost from November to March, and dry; then repot them, place them in a hotbed so as to start them into growth, and harden them well off before planting out.

CHEAP HOUSE FOR TEA ROSES (*Idem*).—It would be best with the front glass, but you need not have the front more than from 2 feet 6 inches to 3 feet high, and then boards would answer, but there is so little difference in the price that we should prefer glass. We would have two boards' height of wood, or two boards 11 inches wide, and one of them hinged for ventilation; then 2 feet 6 inches of glass, with the ends of glass down to the wood part. You may provide for top ventilation by a board hinged at top, so as to open the full length of the house. Have you no wall against which to place it, so as to save the expense of the back? Wood would no doubt answer.

ROSES PRUNING, &c. (*De la Bourbon*).—Advice on the matter of pruning is no doubt often conflicting, as much depends whether Roses are wanted for exhibition purposes, or for ordinary garden decoration, or, again, for cutting for the house. If Roses are wanted for exhibition, the first blooms from budded Briars, or the second year's from vigorous growth on the Manetti stock, are the best; but for general garden purposes we recommend all old weakly wood to be cut clean off, and strong shoots to be well shortened—the laterals on strong shoots to four or five eyes, and on weaker shoots to two or three eyes. When Roses are grown on Manetti stocks it is a good thing to cut right away to the base all wood that is more than two years old, so as to encourage the plant to push fresh shoots from the base. The strongest shoots from the base of the current year's growth generally do not push any laterals the first year, but flower at the ends in the autumn. These ought not to be shortened too much at first, but may be cut about the height that the rest of the bush is left after pruning. They will give very fine blooms next summer from the upper eyes that are left, and push lower down in autumn to furnish strong wood for another year. We should advise you in the case of your Roses on the Manetti stock, planted out of pots in August last, to prune the leading shoots to about 15 or 18 inches, according to their strength, and to shorten the laterals to three eyes. It is difficult to give advice without seeing the plants, and it is necessary to study the habits of the different varieties of Roses, as some require close pruning, while others will not stand it. Such sorts, for instance, as *Blairii*, *Cloth of Gold*, *Solfaterre*, and *Mar-chal Niel* only require to have their shoots thinned, and the very strong shoots only slightly shortened. These remarks do not apply to standards, which must be pruned to keep a symmetrical head, and only wood of medium growth is to be encouraged; but, as a general rule, when quality of bloom rather than quantity is required, use the knife freely, and do not let Rose trees be overcrowded with old shoots. A little careful observation will show amateurs that Roses produced on the side shoots of stems only one or two years old from the base are finer than those on older wood; and in our opinion, when cutting Roses for table decoration, a dozen good

Roses are worth two dozen inferior, and no poor specimen ought ever to be allowed in a vase of flowers for table decoration.

MARANTA LEAVES BROWNEO (*Vitis*).—We think the browning of the leaves is due to a deficiency of heat, accompanied by too much moisture. Give a temperature of 60° at night from now to March, from 65° to 70° by day, and do not overwater, yet see that the soil is moist and the drainage good. The compost is good, but we would use one part loam, two parts sandy fibrous peat, and one part leaf soil, with one part of silver sand and charcoal in equal proportions. We think the leaves are those of *Maranta lineata* rosea, but we cannot tell from such miserable specimens. The leaves are not diseased.

STORING PEARS (*A Constant Subscriber*).—The fruit keeps best in a moderately dry room, and one cool, yet safe from frost. We should consider a cellar not wet a better place than an attic. Remove the Pears to a light room with a temperature of about 45° a few days before they are required for table. They ought not to be removed from the cellar until they begin to ripen.

SCREEN TO HIDE A WALL (*A Working Man*).—Why not cover the wall? *Pyraeantha* is very pretty, and *Cotoneaster microphylla* will hide every part. If you cannot train against the wall, then we would advise *Berberis Darwinii*, which will bear trimming well, and is very ornamental early in spring when in flower; *Laurustians* is also good; but if they are not close enough you may plant Yew. You may cut it as hard as you like, and make, in fact, a close green wall of it. Now is the time to plant. Allow 3 feet between the plants of *Cotoneaster*, *Laurustians*, and Yew, but the *Berberis* should be 2 feet apart. Manure the ground well; it is the way to get the screen up quickly.

SEEDS SOWING (*N. C. H.*).—You may succeed with all, except, perhaps the *Erythrina* and *Cocculus*, which should be sown in March and placed in a hotbed. The others should be sown at the same time and placed in a cold frame. Pans will be most suitable; they should be well drained, and filled with a compost of two parts fibrous loam, and one part each of sandy peat, leaf soil, and silver sand. Cover every kind of seed with a depth of soil equal to its diameter. Keep close until the seedlings appear, then give air, but not in excessive quantity, and water so as to keep the soil moist. The plants from the seeds sown in the cold frame will need potting-off in October, and should be continued in a frame a year longer, and two years after sowing may be planted out. Those sown in heat should be potted-off when large enough to handle and grown on. They will require protection from frost in winter.

AGAPANTHUS TREATMENT (*E. R. Yorks.*).—We think your hnh is the African Lily, *Agapanthus umbellatus*; but we are at a loss to advise you as to its treatment, as you do not state whether you grow it in or out of doors. If you have it out of doors it will only make a few leaves and not flower. To succeed well it requires a greenhouse, and a compost of two parts light fibrous loam and one part sandy peat, with a free admixture of sharp sand. In winter it should only have enough water to keep the leaves fresh, but when it begins to grow give more, and when it is growing freely copious supplies are required. From May to frost it may be placed out of doors. A rather small pot for the size of the plant is necessary. We may be mistaken in the plant. We know of none by the name you give.

ECHITES SPLENDENS NOT FLOWERING (*A. M. C.*).—The plant is probably kept in too dark a house. Encourage it in spring with a brisk heat and moist atmosphere, potting it when it begins to make fresh growth. Be careful not to overwater, and in winter keep it dry. *Enclaris amazonica* and *E. grandiflora* are identical. The writer of the article about which you inquire is not the gentleman you name.

CABBAGE PLANTING (*An Old Subscriber*).—The plants sown July 30th, and pricked out September 13th, may now be planted out—that is, the strongest of them, in a sheltered situation, deferring the principal planting out until early in March.

FRAMING CAMELLIA PLANTS (*Idem*).—It would be well to remove some from the outside border to a frame, and we advise it to be done forthwith, so that they may have time to root before severe weather set in. There is no advantage in twice pricking off, first in a border and in a fortnight to a frame.

PLANTING ARUMS IN A POND (*Idem*).—None of the Arums as far as we know are aquatic; they should have a sandy soil, with freedom from stagnant water; hence they should not be planted in a pond. If by Arum you mean *Calla* or *Richardia* *athiopica* it should be planted in a foot deep of water.

CAMELLIA BUDS THINNING (*Bismark*).—Three or four buds on each stalk are too many. Reduce them to two buds each. What is it you wish for hints on? We might give you many hints, and still not meet your case. A few good sorts are *Alba pleca*, *Chandleri elegans*, *Economia*, *Fimbriata*, *La Pace*, *Leeana superba*, *Monarch*, *Leopold I.*, *Mrs. Cope*, *Napoleon III.*, *Rafia*, *Rubens*, *Stoyn*, *Valtearedo*, and *Wilderi*.

FAIRY RINGS (*S. Amherst*).—Your fairy rings will continue to get wider and wider every year, as you say. We know of no better means for destroying the fungus without hurting the grass, than sowing the rings thickly with quicklime and a little sulphur. We fear, however, you would have to repeat the operation several times, unless you broke the surface and mixed the lime at once with the fungus spawn. Lime will destroy them if persevered with, and so would sulphur, though more expensive.

KEEPING WALNUTS (*A Reader*).—Perhaps there is no better mode for keeping Walnuts in winter than packing them in dry sand, and changing the sand frequently. The chief objection to this mode is that the nuts want much brushing to get all the sand away, as otherwise the shells would feel gritty. If the sand is dry, air may be excluded by a thin layer of turf. Any neat little shrubs, as *Aucubas*, *Hollies*, and *Cypresses*, will do for a flower garden when the flowering plants are removed, and so would all kinds of *Wallflowers*, *Daisies*, *Pansies*, and early-flowering bulbs.

STORING DAHLIA TUBERS (*A New Beginner*).—There is no better plan of keeping the tubers in winter than to take them up after the first frost, lay them in a shed to dry, and then to store them in dry sand, where they will be safe from frost. We do not see in what way you can improve the size of the flowers, except by thinning the buds, so that the support may be given to a few instead of the many which you probably leave. It is also a good plan to thin out the weak shoots.

TULIP TREE SEEDS (*F.*).—They do not generally ripen in this country, but in so unusually hot and dry season like the past they may have done

so, and perhaps may germinate. We would keep them in dry sand, and early in March sow them in pans of light rich loam placed in a hotbed, to be removed, when the seedlings appear, to a cold frame. Then harden off.

CZAR VIOLET CULTURE (*Mrs. Y. B. A. Z.*).—The best plan is to grow it in cold frames. In May take off the rooted runners, and plant them in a border of good, rich, light loam, and, if the situation is protected from the sun at midday for a few hours, all the better. They should be planted a foot from row to row, and 9 inches apart in the rows. Water well in dry weather, and at the close of September take them up with balls, and plant them in a frame in a warm sunny situation. A hotbed frame used for Cucumbers or Melons will answer very well. Do not put on the lights, and give air in fine weather, using the lights only in cold frosty weather. When very wet keep on the lights, but admit air by tilting them. In very severe weather protect with a covering of mats, straw, or other material.

DEODAR SHOWING CONES (*A Subscriber*).—It is unusual for the Deodar at any age or size to produce cones in this country. There have been, however, a few instances, but in very few instances do the seeds attain perfection. It is probable that the plant producing cones, though only ten years planted, may be a scion of a tree quite as aged as your other trees thirty or more years old. The Deodar is for the most part raised by grafting, and also by cuttings, both cuttings and grafts being taken from parts of trees from seed that may have attained maturity; and we think your younger tree is not a seedling, but a grafted tree, or has been a cutting, both of which modes of propagation tend to earlier cone-bearing. It is known that propagating by grafting, budding, cuttings, and layers has a tendency to promote early flowering, and consequently fruit-production.

THINNING STRAWBERRY CROWNS (*Agnes*).—This should be done in spring when the buds are so forward that it can be seen which are likely to produce fruit. Those in the centre are most likely to need thinning, in order to admit light and air. Three-year-old plants will hardly need thinning as yet, unless the runners have been allowed to have their own way, in which case the plants will require thinning to admit light and air to those left for fruiting. Thinning may be done now or in March.

TREES FOR ARBOUR (*City Garden*).—You do not say whether your arbour is formed of trellis or latticework, and you wish to cover it. Irish Ivy is good, and so is Clematis Vitalba, also C. frankfurtensis. If you wish for an arbour solely of trees, then Hornbeam answers well for the sides, with a Weeping Ash to form a canopy overhead. The Hornbeam should be planted as a hedge, and kept as such with the required openings.

CHRYSANTHEMUMS MILDEWED (*E. S. C.*).—To keep them from mildew, give them abundance of air and as much light as practicable, not standing the plants so closely together as to be crowded. If mildew appear, paint the hot-water pipes with flowers of sulphur, or dust the parts affected, using a coarse muslin bag.

WINTERING LILIUM AURATUM (*Idem*).—Pot them as soon after this as you can, removing all the old soil that comes away freely from the roots. The stalk, when it is quite yellow, should be cut off close to the surface. You may give them 9-inch pots. Pot so that a rich top-dressing can be given in spring. Water gently after potting, but do not keep more than moist over the winter. If safe from frost, the cooler they are kept the better.

TRANSPLANTING SHRUBS (*L. J. P.*).—Now is the best time to move Laurustinus and Portugal Laurels; but as your trees are old we should have preferred moving them at the end of September had the ground been moist then. Indeed, even now, the ground, though we have had some heavy rains, is much too dry for general planting purposes. In moving old trees it is well to take out a trench round each this autumn, cutting off all roots encountered in digging the trench, and going quite as deep as the roots. The trench should then be filled in, and the shrubs left until that time twelve-month, when the trench may be reopened and the plants removed, preserving with the roots as much soil as possible, but taking away all the old soil you can without injuring them. The distance from the stem will be dependant on the size of the shrubs, but in no case need it exceed 3 feet. If the shrubs are much overgrown and straggling, the growths should be well cut in the spring after planting at the beginning of April. Success in planting chiefly depends on preserving as many of the fibres as possible with some soil adhering to them. A good watering ought to follow the removal, so as to settle the soil about the roots.

SHRUBS FOR PLANTING UNDER THE SHADE OF ELM AND BEECH TREES (*A Constant Reader and Admirer*).—Of all the shrubs we have tried under large trees none will succeed so well as the Aucuba, Berberis Darwinii, Berberis dnica, and tree Box are also good. Butcher's Broom (*Ruscus aculeatus*), Alexandrian Laurel (*Ruscus racemosus*), Skimmia japonica, Spurge Laurel, Privet, and Snowberry all do well, and nothing succeeds better than the Ives and Periwinkles. The common Laurel, Holly, and Yew succeed tolerably well, but not so well as the first-named. Dogwood and the Guelder Rose in moist soil are fine; and Berberis Aquifolium, Cotoneaster microphylla, and the common Berberry we have seen in good condition under trees.

MADRESFIELD COURT GRAPE (*Amateur*).—We are not aware if it has ever been tried in a vinery without fire heat, and we rather think it would not succeed well under such conditions; but from what we have seen of it we have little doubt it would do very well in such a place if it had a fortnight or three weeks of heat at the blooming and setting season. The mulching fruit trees with tan during winter is, no doubt, beneficial. We are sorry we cannot say where Amateur Strawberry is to be obtained.

VINES ON A WALL (*E. M. A.*).—There can be no question that the Grapes would be more secure if covered with glass, but we can scarcely advise you as to details, as we do not know how far the pathway is from the wall. If that is only 3 or 4 feet from the wall, the upright glass would be best, with a hipped roof at top. If you could come out 5 or 6 feet, then you might have a sloping fixed roof. The cheapest way to do this would be to have stout posts, a sill or wall plate within 10 inches of the ground, so that a board of that width would be the ventilator, and to use rafter sash-bars for glass 10 inches wide, or wider if deemed advisable. The top end of the rafters might be fixed to the wall, or to a ridge board 9 inches from it, and that would give the means for top ventilation. If you gave us more particulars we might afford you more hints, but you will see good examples in the neighbouring nursery.

POT VINES (*M.*).—On receiving the Vines you will find in what sort of pots they have been growing, and if they are in 13-inch pots, all you have to do is to see that the drainage is good; if it is not efficient, make it

so. Then remove the surface soil as far as possible, replacing it with fresh loam from decayed turf top parts, and one part each of fresh horse droppings and of half-inch bones, with half a part each of calcined oyster shells and of charcoal broken small. This makes a first-rate top-dressing for pot Vines, or, indeed, for those in borders. If the Vines are in 9 or 11-inch pots, pot at once in 13-inch pots, and do not disturb the ball; merely loosen its sides. The next thing you will have to do is to prune them, then place them in a position where protection can be given from frost, or they may be set in the greenhouse if its temperature from fire heat does not exceed 40°. The selection of Vines—viz., Black Hamburgh, White Frontignan, and Victoria or Pope's Hamburgh (Frankenthal), is good. The pots should stand on a stage, or on the soil if they can have sufficient light. They need not be further apart than 3 feet. To start the Vines in a greenhouse we think absurd, for if you give more heat than is required for the plants these will suffer. However, you may start the Vines when you like, beginning with 40° for a fortnight, then increasing the heat to 45°, adding 5° fortnightly until you attain a temperature of 60° at night. By day the night temperature should be exceeded by 5° on dull days, 10° on those cloudy but with clear intervals, and 15° or 20° on fine days.

SALT FOR ASPARAGUS BEDS (*A. B., Hamburgh*).—The salt is that used for cooking. You need not be surprised at this, for Asparagus is a native of the seashore; and, besides, common salt, if used judiciously, is a good manure for many crops.

HEATING A CONSERVATORY (*Erin-go-Bragh*).—We can hardly see how we can advise you, as any pipe or chimney is so objectionable for your small house, and the want of the power to heat it would render it next to impossible to grow anything except hardy evergreens in winter, to be followed by Wallflowers, Violets, and bulbs in spring. Other plants more tender you could only keep by leaving the doors of the drawing-room and dining-room open at night. We do not perceive how the iron stove in the entrance hall could do you any good, as it would be impossible to do as you propose—heat a boiler beneath it, and take pipes under the dining-room floor. If you had any place where you could fix a boiler lower than the floor, so as to take pipes underneath the latter, there would be no difficulty, if you had a chimney near. In your case, as you speak of gas stoves and boilers, we would dispense with the latter, but have one or two small gas stoves with flat tops, to receive a basin of water, and use the largest size of arand burners. These consume the gas most thoroughly; but even then, to be perfectly safe, it would be well to have a very small pipe from one-eighth to one-fourth of an inch in diameter inside, to go from the side of the stove near the top into the open air, the end being turned down a little. This would carry off what little gas was not thoroughly consumed, and even one good burner throws out a great heat.

BOILER (*Seraphina*).—All things considered, a conical boiler fed from the top might suit you best, but, as stated lately, we must decline to say which is the very best. We are confident we could make any of the boilers advertised in these pages the best, according as we resolved on doing so. For all quick work, such as getting up sudden heat to meet sudden frost, the smaller the quantity of water in the boiler in proportion to the surface exposed to the fire, the sooner will the pipes be heated.

INCORUSTATION IN HOT-WATER PIPES (*G. B. G.*).—The best preventive is to put 2 or 3 ozs. of muriate of ammonia (sal ammoniac) in the boiler.

DESTROYING SCALE (*A. Y.*).—You do not say what kind of scale it is you wish to free your plants of, but we presume it is white scale from your alluding to Acacias. The vapour of turpentine will destroy not only all insect life, but cause the destruction of every fresh leaf. We remember a house planted with Vines being painted whilst the Vines were in active growth. Turpentine was used in the paint, and, the house being closed at night, the leaves of the Vines an hour afterwards were drooping as if they were suffering for want of water, but, the ventilators being opened, the leaves recovered their freshness. Some of the younger leaves had the edges browned in the morning. It is not safe to use it for the destruction of insect life where there are plants in growth. The best means of applying it is along with 2 ozs. of soft soap dissolved in a gallon of water used at a temperature of 100°. Allow about six drops of turpentine to the gallon. Syringe forcibly the plants laid on their sides, so that the solution may not wet the soil, and the plants being turned round so that every part may be wetted. This will in most cases free the plants of the white scale.

PLANTING VINE (*R. C. Sideo*).—No season for planting could be better than the present. We think either the Royal Muscadine or the Buckland Sweetwater much more worthy white Grapes for culture in a vinery than the common Sweetwater.

NAMES OF FRUIT (*H. M. P.*).—Your Pear is an American sort called Orange Mandarin. (*H. B.*).—We paid 10d. as carriage for your box. On receiving ten postage stamps we will examine the fruit. (*H. G. M.*).—2, Birmingham;—Stone Pippin; 3, Welbeck Bergamot; 4, Bergamotte Buffo. (*John Garland*).—5, Hughes's Golden Pippin; 14, Ross Nonpareil. All the other Apples are evidently local varieties, with which the Devonshire orchards and gardens abound. Pears: 1, Urbainette; 2, not Knight's Monarch. (*A. O. K.*).—2, Doyenne du Conice. (*A. A.*).—Apples: 1 and 5, Beauty of Kent; 3, Alfriston; 4, Golden Noble; 6, Mauden's Blush. Pears: 1, Bergamotte Cadette; 2, Red Doyenne. (*H. F. Hart*).—The large Apples are Gloria Mundi. We shall refer about Eckinville and let you know. (*Miss Johnson*).—2, Beurre d'Armenie; 3, Soldat Esperon; 4, Conite de Lam; 5, Fasse Colmar; 6, Rousselet Thon; 7, Knight's Monarch. (*J., Birmingham*).—1, Beurre Diel; 2, White Doyenne; 3, Glon Morcean. The Apples are unknown. (*H. F. C.*).—1, Kentish Codlin; 2, Cambridge Pippin; 4, Devonshire Buckland; 5, Lewis's Incomparable. (*James Brown*).—2, Passe Colmar; 3, Napoleon; 4, Josephine de Malines; 5, Louise de Prusse; 6, Ne plus Meuris; 7, Beurre d'Armenie; 8, Brown Beurre. (*Amateur*).—Apples: 1, Reinette Blanche d'Espagne; 2, Cobham; 4, Bedfordshire Foundling. Pears: 1, Crasanne; 2, Beurre d'Ormeau; 4, Forelle; 5, Auguste Kover. (*Mr. Lombard*).—Your Pear is certainly not Marie Louise d'Uccle, but appears to be a remarkably fine specimen of Doyenne du Conice. (*A Subscriber*).—7, Bergamotte Cadette; 17, Old Colmar; 18, Ne plus Meuris; 13, Pomme Poire; 16, Napoleon; 2, Sturmer Pippin.

NAMES OF PLANTS (*Adams*).—We cannot name plants from their leaves only, we must have flowers also. (*A. M'Callum*).—Arctotis repens. Mr. Beaton called it "Frosted Silver Plant," and used it as an edging.

POULTRY, BEE, AND PIGEON CHRONICLE.

PRIZES, AWARDS, AND REFORMS IN POULTRY SHOWS.

The most promising symptom I can see of genuine progress and improvement in the poultry fancy is the greater amount of active interest in shows and other matters connected therewith. Fanciers are not content now to acquiesce quietly in whatever a committee or a judge may choose to lay down for them; awards get discussed and abuses get examined. There never fails to be something well worth the talking about; and some remarks in the last number or two of "our Journal" suggest to me several points in which I think a little change would be very desirable, while it could offend the prejudices of none.

For instance, in speaking of the Birmingham Malay classes, Mr. Brooke justly remarks on the great difference between the value of the first and second prizes; but the criticism has, I think, a much wider application. Time was when one really first-rate pen in a class was perhaps the ordinary rule, but it is not so now by any means. In all the great shows of the year, and in most even of the second rank, the greater number and the far sounder knowledge of the exhibitors have made the competition very close and severe. Again and again have judges no small difficulty in deciding which shall be first, second, and third; and as often have I noticed cases in which any breeder would give as much for the one pen as the other; or as the Irishman said, one pen "was as good as another, and a great deal better." The question arises, Should not the value of the prizes show less money difference? It is not a question of justice, for no injustice is really done; it is a matter simply of expediency and popularity. The honour of being first would remain the same, but I have reason to believe that an increase in second and third prizes, even at the expense of the first, would tempt more exhibitors to many a show.

As I have mentioned the Malay class, let me state the pleasure with which I hear from Mr. Brooke that I am again to see some real big birds again, and that some fresh breeders have started them. I think, however, that "Y. B. A. Z." is wrong in attributing the deterioration in the breed which he admits to having "so little encouragement." Is it not rather the other way, as I endeavoured to make clear? My impression is that no breeder ever lost ground from want of prizes, but rather, as breeds have lost popularity, committees have been forced to decrease prizes in sheer self-defence. To take solitary examples is not safe. I have often noticed an almost empty class one year fully filled the next, and *vice versa*; but the committee of no show can or will go on giving prizes to any variety which it is found repeatedly does not pay by its entries; whilst, on the other hand, every leading variety but Dorkings, Spanish, and Hamburgs has had no difficulty in fighting its way up in spite of "no encouragement." I would not have named this point again, but that I think its candid remembrance would save much sore feeling; not to "Y. B. A. Z." certainly, who has never shown any, but to some other occasional complainants, who seem to think that their favourite breeds have a kind of abstract right to as much and as many prizes as any other. Let them make their pet breed popular, and committees will give them all the "encouragement" they desire; and meanwhile they are only fighting the same obstacles which Brahmas, Hondans, Crève-Cœurs, and others have successfully vanquished before them.

Another point, however, seems to me to be now of importance, and that is, that the published awards at shows should have some regular, recognised, and standard value. I am not speaking of the value given to them by the known ability of the judge, but something by which a simple reader of the award list should be able to form a tolerably correct notion of the real value of the pens and the character of the competition. Nothing could be more easy, while at the same time nothing, it seems to me, can at present be more important. Many still speak of the poultry fancy as a mere hobby, while in point of fact it has become a very serious business, carried on by many of the highest, fairest, and most honourable in the land; and the mere amount of money invested in it, if calculated, would make every reader of this Journal stare. Such interests as are concerned ought by no means to be laughed at or left to chance, as they often are now; whilst a systematic theory of awards

would in itself and by itself go very far to supply the place of the more extended reports only too justly longed for by "SHROPSHIRE RECTOR." At many shows a commendation is really worth more than a prize at others, yet there is at present no means of distinguishing between one and the other; whilst only the other day, in a judge's report, it was stated rightly that a particular class was all through "of extraordinary merit," whilst, besides the two prizes, the judge only awarded a simple commendation to one solitary pen!

If I be asked how this could be amended, what I would propose would be that the award of "very highly commended" should be given to all pens, and to those only, which in any ordinary show would be thought worthy of a place in the prize list. I say to all, because the number of such awards would always be then a guide to the quality of the class. If, besides this, the pens "highly commended" were arranged in their order of merit, I think all that is necessary would be done, and the list of awards alone would then present a real index for the use of absent breeders, which it certainly does not now. In the case of those catalogues which, like the Bristol, give the awards in the margin instead of in a separate list, the order of the pens highly commended could be shown by numbers, and in the mere commendations I think order of merit would be hardly necessary. Nothing could be more easy, and I venture to think hardly anything would be of more use to the body of poultry fanciers. I would much like to know the views of Mr. Hewitt, than whom no one is better acquainted with the important interests involved, upon this subject, and I had meant to ask them privately before mentioning it in these columns, but the remark of "SHROPSHIRE RECTOR" respecting the want of information leads me to broach the question now.

Regarding trimming, which two correspondents have recently mentioned, I think "ALQUIS" has either not seen or has forgotten Mr. Hewitt's suggestion as to a punishment. I have not yet lost my interest in the matter, but I always have and always shall object to any rule precluding an offender from showing again, as not being analogous to any law either Divine or human. I think Mr. Hewitt's suggested penalty severe enough. But in one thing "ALQUIS" is quite right; the whole matter now rests with committees. No one can say now that judges will not act. Mr. Hewitt has formally asked for more power, and expressed his willingness to accept all the responsibility; he will pass the judgment if the "civil power," in the shape of committees, will enforce the penalty. I regret to have to add that I have been forced to the conclusion that a great many committees have no desire the abuse should be discouraged, for the simple reason that many of themselves or their friends are too deeply compromised. I quite understand, and was much amused at, the delicate allusion of "A DISGUSTED EXHIBITOR" to the "pickled" feathers; and in answer to his inquiry as to Birmingham, I beg to say that the inaction of the Council is not for want of reminder. Many readers will remember that a while ago I spent much, both of time and money, upon this matter; and a year since I sent them a copy of the protest against the practice, signed by over fifty of the very best names in the fancy, with an earnest appeal, if they could not see their way to anything further, that they would simply state that their judges would be "specially requested" to disqualify all fraudulently trimmed birds. I do not know on what ground any committee could refuse at least as much as that; but the Birmingham folks did, and the annual spectacle which followed as usual disgusted not only your complaining correspondent, but—L. WRIGHT.

POULTRY SHOWS,

THEIR MANAGEMENT AND REPORTS.

THE new county rector of "our Journal," and may their name be legion, I mean "SHROPSHIRE RECTOR," has, I fancy, had but little acquaintance with poultry shows, or he would have found that the great number of committees do not at all consider that "every exhibitor whose entries amount to, say, 10s., is entitled to a ticket of admission." I cannot answer for the northern shows so much; but in the south, with the exception of Bristol and Clifton, and Lord Tredegar's Show at Newport, there is no free entry to exhibitors. In the north, I fancy, they are more liberal; certainly both at Middleton and Roshdale exhibitors were sent tickets, at least I was, and this is as it should be. I feel confident the omission is an injury to a show. The fact of receiving such a ticket elicits additional sympathy in the success of the show, and often decides a doubtful exhibitor on visiting it. I have often advocated the

adoption in your pages, but committees, as a friend of mine is fond of remarking, "don't seem to see it."

The matter of the catalogue also, is a serious annoyance to exhibitors. Certainly exhibitors are the back bone of an exhibition: this, I suppose, is granted. True, many obtain their *quid pro quo*, but many do not. I apprehend that in a good show the latter class form the majority, and surely it would be wisdom on the part of committees to show this little courtesy, by sending one to those to whom, after all, they are indebted for any exhibition at all. Then, again, it should be the first duty of the Secretary, after the publication of the catalogue, to dispatch them by *first post* to distant exhibitors. Before now I have ordered my catalogue, have left home on the second day after its non-arrival by post, have arrived at the exhibition, and found that all the catalogues were sold on the first day; mine, although previously ordered, sharing the same fate! Some committees—and here our grandmother, Birmingham, sets the example—wipe their hands of all catalogue business. In this case, it appears to me the duty to sell this part of the transaction with the understanding that each exhibitor shall be furnished with a copy as early as possible.—Y. B. A. Z.

WEIGHT OF FOWLS INFLUENCING JUDGES AT POULTRY SHOWS.

I HAVE often been asked why I did not exhibit at Birmingham? My answer has invariably been, if I did with any chance of success, I should for ever spoil my birds for breeding. I exhibit nothing but Dorkings, still the same objection applies to all the large breeds. Why are the exhibitors of the large breeds compelled to fatten their birds to such an extent as to utterly ruin the birds for breeding? Surely the frame ought to be the criterion, not the weight. If you get the large frame, weight is merely a question of feeding. True, you cannot get a large frame without good feeding, but after you have the frame why should you be compelled to ruin your birds so as to put on extraordinary weight? This, to me, is one very great objection to the Birmingham Show. Let frame, not weight, carry the honours, and then both the Show itself and the public generally, as well as those who delight in poultry, will benefit by the change.

Although no novice, let me from sad experience warn intending purchasers of the large breeds against buying prize birds at Birmingham, unless they can satisfy themselves, which I have never been able to do, that the birds are not so fat as to be utterly useless for breeding. Mr. Wright's excellent letter has led me to make these few remarks, in the hope that some one of influence in the poultry world will take up the cudgels in favour of frame *versus* weight.—THOS. E. KELL, *Wetherby*.

[We are in a position to say, the Dorking prizes at Birmingham have never been awarded by weight. The judges would have wilfully deviated from their instructions had they done so, and, we believe we may add, from their own convictions. Those who believe such a report believe it on hearsay, and hearsay is a bad authority.—Eds.]

SELECTING FOWLS FOR EXHIBITION.

[Our Canadian brethren are going ahead; we extract this from the *Canadian Poultry Chronicle*.]

THE first care of an exhibitor should be the proper matching in colour of his birds for the show pen. The want of attention to this point causes the frequent loss of a first prize to many otherwise well-deserving pairs of fowls. They may be all that the most fastidious amateur can desire, if taken singly and examined by the scale of points, but yet matched as they frequently are, judges are compelled to pass them by without recognition, much to the chagrin and disappointment of the exhibitor, who, in ignorance of the real cause, not unfrequently attributes to them incapacity, or perhaps something worse. Exhibitors should never forget that birds not matching in the show pen are invariably disqualified by all judges who know anything of the principles laid down for their guidance in such matters, no matter how perfect they may be in all the other points. Size, too, beauty of plumage, markings, symmetry, condition, &c., ought also, all in their turn, to be carefully considered, and each point of the bird carefully scrutinised before being selected for the show pen.

Poultry-breeders are indebted to the London (England)

Poultry Club for the "Standard of Excellence" for the guidance of judges in making their awards, a knowledge of which is equally essential to the exhibitor as the judge. Without it he is unable to make his selections with any degree of certainty of obtaining a prize; with it, he is sure of his birds not being disqualified, even supposing he may not be so successful in the much-sought-for honour of prizetaking.

The "Standard" places a separate value in numbers on each point of excellence, which, when summed up, make a total of fifteen for each bird. The values attached to these points are not alike in all breeds of fowls. In some they are calculated on a different scale to that of others, a thorough knowledge of which makes the successful exhibitor and good judge.

In the Cochin breed, the varieties known as Buff, Lemon, Silver Buff, Silver Cinnamon, and Cinnamon, size and colour are highly estimated; to these two points the value of seven is assigned out of a total of fifteen, the former having three, and the latter four given to it; while to the six remaining points—viz., head and comb, carriage of wings, legs, fluff, general symmetry, and condition, a value of eight is attached. In the Grouse and Partridge varieties of this breed, instead of a general value of four being given to colour, it is divided into sub-values of two each, on account of the more specific markings of the feathers of these birds, and which exhibitors would do well to note. The value of points in White and Black Cochins are the same as in the Buff and Cinnamon, the difference in colour only considered, and the same remark holds good as to Dark or Pencilled Brahmas, and Light Brahmas, as to the values of points.

To breed to size as well as feather has long been the chief feature of the Dorking breeders. That this should be so is not to be wondered at, seeing the prominent place assigned to it in England as a table fowl. Special value is therefore given to size in the Dorking class beyond that of any other class or breed of fowls, except to La Flèche, Turkeys, and one variety of Ducks. In the Coloured Dorking size counts five, symmetry four; while head and comb; legs, feet, and toes; and condition, count but two each.

To the White variety a point of excellence is given not recognised in the Coloured—purity of plumage, on which a numerical value of two is fixed. To make up this a deduction of one is made from each of the two points size and symmetry, reducing their value to four and three respectively, instead of five and four as in the Coloured.

A still further deduction from size is made in the Silver-Grey variety, and added to colour; thus we have in the Silver-Greys the points size, colour, and symmetry, all ranked of the same numerical value—three, while the other three points rank as in the Coloured, two each.

The Spanish breed of fowls has only one recognised variety, although there are several sub-varieties, known as the Minorca, White, Andalusian, and Anconas. Face, ear-lobe, and symmetry are of equal rank, each point counting three; comb, condition of plumage, and purity of white face and ear-lobe, count two each. Of the six points to which the numerical value of fifteen is assigned, the face and ear-lobe count eight—over one-half. It will be seen, therefore, of how much importance it is to select fowls of this breed with face and ear-lobe free from those red blotches which are so frequently met with in birds of this variety.

The points of the numerous varieties of Game Fowls, usually known as the Black-breasted, Brown, and Ginger Reds, Yellow, and Silver Duckwing, Birchen Yellow, Pile, White, and Black, are seven in number. Colour of plumage ranks the highest, and has a value of three given to it; while shape of head and neck; body and wings; tail; thighs, legs, and toes; symmetry, handling, condition, and hardness of plumage, have each a numerical value of two.

Of the many breeds of fowls which are to be met with at an exhibition, there is perhaps none which attracts the attention of the visitor more than those of the Hamburg class. The beautiful markings of the feathers of the different varieties known as the Gold and Silver-pencilled, Gold and Silver-spangled, and Black Hamburgs, call forth his admiration, and ought to be an increased incentive to exhibitors in the exercise of great care in the selection and breeding of these fowls. In the Gold and Silver-pencilled Hamburgs there are in cock birds six points of excellence, three of which—comb; colour of plumage, except tail, sickle feathers, and tail coverts; and colour of tail, sickle feathers, and tail coverts—count each three; the deaf ear, symmetry, and condition numbering two each. The hens have a similar number of points, but vary in name and numerical value—comb, deaf ear, symmetry, and condition numbering two each; while purity in colour of head and neck;

purity of ground colour, and accurate and distinct pencilling, in every part, except head and neck—count three and four respectively. The difference in markings between the Spangled and Pencilled varieties call for a separate classification of points. In the Gold and Silver-spangled Hamburgs, then, the comb, deaf ear, breast, under parts of body and thighs, wings and bars, symmetry, and condition, of the cocks should each number two, and colours and marking of head, hackle, back, saddle and tail three; whilst in the hen, combs, deaf ear, bars, symmetry, and condition count two. Neck most distinctly and evenly striped, one. Remainder of plumage (except tail in Golden) clearness of ground colour, evenness and distinctness of spangling, with rich, large, round spangles, four. In the Black Hamburgs, plumage and shape each count four; comb, head, and face, three; deaf ear and condition, each two.

The Polish variety are not of recent days nearly so numerous as they at one time were. A really excellent specimen we have not for some time seen. The exhibitors of this breed will not, therefore, have so many competitors to contend against; they ought not, however, on that account to be the less careful in the selection of their exhibition birds. There are three acknowledged varieties, White-crested Black, and Gold and Silver-spangled. In each of the three varieties, size of crest and shape of crest each count three; symmetry and condition, each two. The other points, however, differ. In the White-crested Black richest black plumage counts two; deaf ear, one; and crest of the purest white, and most free from black, two. The remaining points in the other two varieties are—colour of crest, one; plumage accurately marked according to the "Standard" rules, two; purity of ground colour, one; bars, one.

We are glad to see the French breeds of fowls increasing in popular esteem, and that an additional class has been assigned them this year at our provincial fair. There are of this class of fowls three recognised breeds—Houdans, Crève-Cœur, and La Flèche. To the Houdans are allotted six points, which count as follows:—Size four; crest four; symmetry, plumage, and condition, each two; five claws, one. The Crève-Cœur have also six points of excellence—viz., size four; crest and colour three each; shape, symmetry and condition two each; comb one.

The La Flèche have five points given them—size, five; comb, shape, and condition, each three; deaf ear, one.

Game Bantams are seldom exhibited at our shows. Their points are seven—smallness of size, shape of head and neck, of body and wings, of tail, of thighs, legs and toes, and condition, each two; colour, three. Sebright Bantams, Gold and Silver-laced, plumage most evenly and distinctly laced throughout counts four. Purity of ground colour in Silver, and richness and clearness of ground colour in Golden, comb, smallness, symmetry, condition and general appearance, each two; tail, one. Black and White Bantams are judged by one standard—purity of white, or richness of black; smallness and symmetry each count three; while comb, deaf ear, condition, and general appearance count two each.

In Turkeys, size, symmetry, and colour are the leading characteristics of birds for a show pen; while the same may be said of Ducks and Geese, with the exception of Black East Indian and Call Ducks, in which smallness of size is the chief feature.

Exhibitors should also bear in mind that to each distinctive breed are attached certain disqualifications, which birds selected for exhibition ought to be free from.

CRYSTAL PALACE POULTRY AND PIGEON EXHIBITION.

This, to be held on the 7th, 8th, 9th, and 10th of December, ought to be largest and most successful of the year. For poultry there are eighteen silver cups, or pieces of plate, varying in value from five to six guineas, in addition to the three money prizes in each class, of £3, 30s., and 10s. For the Pigeons there are seventeen silver cups, or pieces of plate, varying in value from five to three guineas, in addition to the three prizes in each class of 30s., 20s., and 10s.

SOUTHAMPTON POULTRY SHOW.

You announced my intention of collecting subscriptions for Light Brahma cups to be given at this Show. The following is the result of that collection:—Mr. Hickman, £1 1s.; Mrs. Williamson, £1 1s.; Mr. Crook, 10s.; Mr. Maynard, £1 1s.;

Mr. Dowsett, £1 1s.; Mr. Pares, £1 1s.; Mr. Rodbard, 10s.; Mrs. Turner Turner, £1 1s.; Mr. Crowley, £1 1s.; Mr. Worthington, 10s.; Mr. Seecombe, 5s.; Mr. Chisman, 5s.; Miss Harvey, 13s. Total, £10 10s. Mr. Dowsett has collected six guineas for a piece of plate, which will be awarded to the best pen of Light Brahmas at the next Birmingham Show.—H. M. MAYNARD.

I beg to call your readers' attention to the fact, that there is a Game cup, value five guineas, to be awarded to the best pen of any variety of Game. I should remind them that the entries close on the 20th inst.—S. SAMWAYS, *Bevois Town Hotel, Southampton.*

INQUIRY.

In your impression of the 6th of October there is an advertisement from one who signs himself J. Panshon, Downe Street, Driffield, and who represents himself as having 150 head of prize poultry for sale. Being in want of some Cochins I was induced to go over to find the man, but failed to do so, as I am ascertained there is no such person in Driffield. Report pointed to a person who, under this name, is endeavouring to sell some very inferior stuff, and whose hen-roosts are full of several kinds of disease. I merely write this as a caution to others whose time, like my own, is too precious to spend a whole day in searching for a man unknown in the neighbourhood he is said to live in. If people wish to dispose of their poultry, surely they should give a proper address.—EAST YORKSHIRE.

RABBITS AT THE COMING YORK SHOW.

I CONGRATULATE the Committee on the attractive prize list they have issued, and trust it will find favour in the eyes of all Rabbit-fanciers, and induce them to send numerous entries, so that the York Exhibition of this year may be as far superior in number of entries and excellence of specimens as it exceeds all previous years in the liberality of the prizes offered. It is not often we find two five-guinea cups and a silver medal given for rabbits, yet such is the case at York. The medal is from the neighbouring county (Lancashire), and I am glad to see this kindly feeling and interest manifested in such a manner by the fanciers, and I do hope to see more evidence of such feeling. I am not yet able to state the name of the Judge, but can assure all exhibitors that a good judge of Rabbits will award the prizes; and a full report in this Journal of his awards, and the particulars of excellence of each prizewinner, will be given by a gentleman well known for his ability to assume that office. Thus the Committee are doing all they can to add to the attractiveness of the Rabbit section of the Exhibition, and I am aware that a large number of entries will crown their efforts. There are eight classes for Rabbits, and the small two-shilling entry fee, and the good £1 and 15s. as first prizes, I think will induce a liberal response.—CUNICULUS.

HOW TO REMEDY THE DEFECTS IN BELL-SHAPED BEE-GLASSES.

HAPPENING to be at a dinner party lately, the conversation turned upon bees, and two or three of the company made remarks to the effect that very few swarms had been seen on the wing this season: whereupon a rich merchant, just returned from Burmah, stated that the country was quite overstocked with these honey-gatherers, and that no complaints as to swarms or their produce had ever been made in former days, when only a hive or two could be found here and there in a district.

Being anxious to hear the sage remarks of the returned foreigner, I inquired on what grounds he concluded the country was overstocked? To this he replied that it required an acre of pasture ground to maintain a cow, and that it would require the same extent of territory to maintain a bee. There was nothing, he added, to prevent a single bee from visiting and extracting all the honey from every flower within the space referred to during the season. It never once occurred to him that nectaries emptied one day might be replenished the next, or that periods might happen when supplies would be so abundant as to be all but inexhaustible. These facts I endeavoured to make apparent, but I fear without success. The mention of the discoveries made by Dzierzon was received with something more than a smile of incredulity, and I could not help thinking that my situation bore a striking resemblance to that of an old clergyman near Silloth, and a genuine son of Erin. A friend

called upon him one day to inquire how he was getting on. "Very badly," was the reply; "I have been here eleven years, and I don't think I have done any good." Then pointing to a gathering of Methodists in one of the fields, he exclaimed, "You have no conception of the pape I have to deal with; they are all teachers, but none of them are taught. When I tell them of the 'Principia' of Newton, they say it is all nonsense; or if I speak to them of manners, they say Lord Chesterfield was a fool." My auditory were evidently of the same opinion with the old clergyman's parishioners. They said plainly, though not in words, that parthenogenesis was nonsense, and that Dzierzon was a fool. But what can an apiarian expect when he throws his "pearls before pigs?" The readers of "our Journal" belong to a different class, and I have no doubt that most of them are ready to hear patiently any statements that may be honestly made, and to bring them to the test of experiments.

With their permission, then, I venture to say that the best bee glass that has yet been devised is that so well described by the "RENFREWSHIRE BEE-KEEPER" in "our Journal" of June 4th, 1868, and that the worst is the bell-shaped, which I have generally used and still continue to use in my apiary. Possessing several of the latter form, I was unwilling to throw them away; and this led me to adopt an expedient whereby their defects might be in a great measure obviated. The chief defect, as those who use them must know, is the difficulty which bees experience in ascending them. The bees' efforts to do so are repeatedly frustrated, and, when they succeed, the next difficulty is the fixing a foundation for their combs. Now the former of these inconveniences is not found in the form of glass devised by Mr. Mitchell, of Abingdon, and both may be overcome in the common bell-shaped by the following process:—Warm the glass before a good fire, exposing the interior to it, until it is sufficiently hot to melt wax. Then take a piece of clean comb, and draw parallel lines from top to bottom where you wish your combs to be fixed. Portions of comb will adhere throughout the lines to the heated glass, and these, if the temperature has been raised to the proper mark, will not only prove excellent bases for future operations, but will also serve as ladders, affording all needed facility of ascent to the bees. Having tried the process and found it successful, there is reason to hope it will succeed with others also.—R. S.

OUR LETTER BOX.

COCHIN PULLETS DYING (E).—You do not give us sufficient information about your fowls. From your description, we should say they become diseased after they come into your possession. If you will give us a description of the place they have, and the food afforded them, we shall be able to form an idea as to the disease and its remedy. At present all we know is that at certain intervals you lose one of your fowls.

FEATHER-LEGGED WHITE BANTAMS (G. M.).—There is a very handsome breed of White Bantams, called the "Booted Bantams." They have now become scarce because all Bantam-fanciers turn to the Game. They have not, and never had, a fixed weight, but, in common with all others, the less they weigh the better and more valuable they are considered.

BIRMINGHAM POULTRY SALE (W. Carr).—You had better write to Mr. Lythall; he can give you authentic information.

ANDALUSIANS (Very Old Subscriber).—The Blue Spanish or Andalusians rank as a distinct breed. Without giving an opinion on the Darwinian theory, we believe they are offshoots from the Spanish, just as we believe the modern Spanish is an offshoot from the old Minorca. They have been shown as a separate breed everywhere, but never in sufficient numbers to entitle them to a class. They always belong to the "varieties," and compete therein. Mr. James, of Fareham, used to keep them very successfully. Apply for a sitting of eggs to the person who shows the best of the breed at Birmingham.

HEN'S HEAD SWOLLEN (J. W.).—If the swelling be a hard one, you can either treat it with iodine ointment, or you may carefully open the skin, and squeeze the swelling out by pressing the lower part. If it be soft it is merely the result of cold, and as Braamias are not subject to roup it will have no consequences. The treatment will be to give only ground food for a day or two, to administer stimulants in the shape of bread and strong beer, and to give either Bailey's Pills, or pills of campher the size of a garden pea—two at a time and once per day.

BRAHMA COCKEREL (Brahma).—We should not hesitate to breed from him.

AYLESBURY DUCKS' BILLS BECOME YELLOW (E. H.).—It is a very vexatious thing that the bills of Aylesbury Ducks turn yellow, but it is not less true that they do so in certain localities. Water that runs off peat or heath, stagnant ponds that receive stable or yard manure, and dirty water of every kind, are injurious to the colour of the bill. A clear running stream, access to meadows at daybreak when the grass is covered with cold dew or white frost, and the mixture of small pebbles or stones with the only water they have (where it is supplied artificially), are all beneficial to the colour. It is hardly necessary to say gravel stones are very bad to mix with water.

ANTWERP PIGEONS (Severel).—It is only necessary to refer several correspondents to our number for February 17th, for the Birmingham Columbarian Society's standard of merit, to which may be added, in answer to one inquirer, "TRUE BLUE," that the white-eyed specimens of

the Antwerp are very numerous, and amongst them are some of the most perfect birds, more especially amongst the Red Chequers and Blues, although all the varieties are pretty sure to breed some white-eyed birds, which is not a positive defect, yet the fact of its similarity to the eye of the Barb, leads us to prefer the deep blood-red-coloured eye; yellow and dingy-coloured eyes are objectionable, and lack that fierce, fiery appearance so essential in that great point, the eye of an Antwerp.

VARIOUS DISEASES IN ONE LOFT OF PIGEONS (David Laurie).—The various diseases you mention as being rampant in your Pigeon loft—falling of the feathers, or feather-rot, blindness in young birds, formation of matter in the joints, and loss of power in the legs, all point to one cause—viz., bad constitution, and that in no common degree. Most probably your stock have in other hands been bred in-and-in for generations; and bad food, bad water, bad air, and crowded and unclean lofts, causing the birds to sleep in air charged with exhalations from dung, have helped to bring about your troubles, and your own care may have been fruitless to prevent what former years have caused. Fresh blood and frequent crossings will help you to get rid of the scrofulous taint; or, better still, get a new set of birds, for scrofula lingers for generations.

REMOVING STOCKS (Brixtonensis).—We do not think you need fear the effect of the removal on your ponderous stocks in Woodbury hives. More harm than good would be likely to arise from disturbing the hives in order to insert a transverse notched bar at the bottom of the frames.

METEOROLOGICAL OBSERVATIONS

In the Suburbs of London for the week ending October 18th.

COVENT GARDEN MARKET.—OCTOBER 19.

We have still to report an excessive supply in most of the ordinary kinds of produce, orchard fruit being especially abundant, and large consignments of Pears from the south-west of France reach us every week. The Potato trade is somewhat dull, with large stocks on hand, chiefly Regents and Flukes, ranging from 80s. to 120s. per ton.

From observations taken near London during the last forty-three years, the average day temperature of the week is 54.4°, and its night temperature 37.3°. The greatest heat was 67°, on the 31st, 1854; and the lowest cold 22°, on the 28th, 1836. The greatest fall of rain was 1.03 inch.

SLOW COMBUSTION—ENDURING FIRE—ECONOMY IN FUEL.

HAVE read with interest the various notices which have from time to time appeared in the Journal, giving particulars of different boilers and modes of heating glass houses.

The plan I have adopted, and which has been attended with marked success, although not new, yet is not sufficiently known, and therefore may be of interest to those amateurs who, like myself, are obliged personally to attend to the work required.

I must preface my statement by mentioning that my house is 35 feet long, 14 feet from back to front, and 13 feet high. It is heated with hot water by one of the smallest-sized tubular boilers, having 4-inch flow and return pipes running round the two ends and back of the house.

Whether or not it was from the position of the furnace house I cannot say, but whatever the fuel I used I found a difficulty in keeping the fire burning for any length of time so regularly as I desired, in consequence of the draught through the ashpit door setting on one side of the fire. As a result it frequently went out, and the heat was irregular. After trying several plans to prevent this, I at last had two holes, each about the size of a crown-piece, drilled in the ashpit door. Over these I had soldered a good-sized brass sliding valve, similar to those frequently used in doors to ventilate rooms. The result was all I desired. By this simple plan I obtained a properly distributed draught under the whole of the fire, and by a little attention to the damper and quantity of air admitted through the valve, I was soon able to ascertain the amount of draught requisite to keep the fire at its proper heat.

I also found that by only feeding the fire twice a-day—the first thing in the morning, and the last thing at night—and just clearing the bars, if needed, the fire was kept constantly going, and during the three winters once only has the fire gone out, and on several occasions it has burned for twenty-four hours without additional fuel.

I have often been surprised at the small amount of air needed to keep up a bright clear fire. With the valve open in each span not more than the thickness of a new sixpence, I have kept the house at from 40° to 45°, with an external atmosphere showing 16° of frost. With a temperature of 6° to 8° below freezing I have kept the house at 40°, at the same time having the two end ventilators open.

The great advantages of the plan are—the length of time the fire can be kept burning at a proper heat without attention (a great object to an amateur engaged, like myself, in business away from home), and the perfect control over the heat, be it little or much. One essential to success is keeping the ashpit clear of dust and ashes; I have it cleared out two or three times a-week if needed.

During the last two years the fire never went out from the time I commenced until I ceased heating the house (about five months each season), excepting when I drew

the fire to clear the bars, and this I did about once a-month.

Not wishing to annoy my neighbours with smoke, I tried various kinds of fuel—breeze from the dust yard, coke breeze, furnace coke, gas coke, and Welsh anthracite smokeless coal. I carefully noted the cost and result of each kind, and finally adopted the Welsh anthracite coal as being the cleanest, as cheap as any, if not the cheapest, and by far the easiest managed. Residing in a northern suburb of London, I have no difficulty in procuring this; and, at 25s. per ton, I find its cost does not exceed 3s. 6d. per week. I have been surprised how little this cost was exceeded, when on several occasions, by way of experiment, I gave an increased draught to test the power of the fire under the plan adopted. For the reason stated, I have always a smokeless fuel, and therefore cannot say how ordinary coal would answer.

The size of the brass valve is 6 inches long, and the whole affair cost about 8s.

I may attach a fancied value to the results of my experience, but I give the particulars for the benefit of your amateur readers, if you think them worth inserting in the Journal.

I found by repeated experiments that by using the valve only I could drive the heat far in excess of anything I might require, and I also had the satisfaction of knowing that, however sharp the frost might threaten to be before morning, I could always retire to rest without any fear about the greenhouse fire.—R. S.

JASMINE GRANDIFLORUM FOR AUTUMN AND WINTER FLOWERING.

There are some flowers which from their purity of colour, beauty of form, and perfume are general favourites, and of these the Sweet Jasmine is undoubtedly one. It may not be in such high repute as the Rose, but it is one of many old plants without which no garden is complete.

Jasminum grandiflorum, though not such a favourite as the old Sweet Jasmine (Jasminum officinale), is nevertheless an old plant, having been introduced in 1629. It has, no doubt, found a home in some gardens since that time, yet it was only of late years that this plant came to be cultivated, and even now it is not so common as it deserves to be; indeed, it ought to be grown in every greenhouse. Those who do not possess it would by now securing plants obtain a fine, white, sweet-scented flower that may be had in blossom early in spring by slight forcing, and the same plant will flower again in autumn, and continue expanding its blossoms successively during the dull autumn and early winter months.

In appearance it is a *far simile* of the Sweet Jasmine, with this difference, that its leaves are larger, the flowers more than twice the size, some double, but not twice as sweet, though it is very sweet-scented, and all the flowers do not open at once, but succeed each other as in the Sweet Jasmine. We cannot cut the whole produce of a stem at once, but each flower has a good stalk, and is quite large enough by itself. It would be useless attempt-

ing to grow this as a pot plant on its own roots—at least I have not seen it in a satisfactory state when grown in that way. It requires to be grafted, and on a stem from 6 inches to a foot high it is very pleasing. It is best grafted on the old sort, or Sweet Jasmine, and the operation may be performed in spring when the stocks are beginning to grow, the scions being kept back by cutting them a month previously, and keeping them fresh by inserting their lower ends in wet clay; or a Potato pot in the soil will do as well. Whip-grafting will answer, but the continental growers practise cleft-grafting with great success. After tying with bast matting, and covering with grafting wax, place the grafts in a gentle hotbed or a house with a temperature of from 50° to 55°, and cover with a hand-glass, so as to keep them close. The glasses ought only to be taken off to see whether water is required, or to admit a small quantity of air if likely to be damp. When the grafts begin to grow admit air in moderate quantity at first, increasing the amount as they advance, and hardening off by degrees. When the shoots are about 6 inches long the plants may be moved to the greenhouse, assigning them a light airy position. They will flower in the course of the summer if sufficiently strong. By autumn they will have firm shoots; to insure their ripening, give them the lightest and most airy position the greenhouse affords, keeping them dry at the root, but not so much so as to cause the leaves to flag and fall prematurely.

When the leaves fall place the plants in the coolest part of the house, or in a cold pit or cool house, and in December cut them back, so as to leave about an inch of last year's wood, two or three joints being enough. If the plants are in small pots transfer them to a larger size, using a compost of light fibrous loam two parts, one part sandy peat, and one part of leaf soil, with a free admixture of sharp sand. Good drainage is necessary, also a moderate-sized pot. Six inch pots are quite large enough for the next two or three years. After watering, the plants may be placed in a house with a temperature of 45°, progressively increasing to 50° or 55°, and they will flower well early in spring. They will, of course, be placed in the greenhouse when in flower, and should have due care as to water, and in a light airy position the wood will be ripened by May. Then, or early in June, cut the shoots back to within a few eyes of their base—two or three are enough—and keep them rather dry at the roots for a fortnight, then place them in a light airy position, watering as required, and occasionally syringing overhead. The plants will form fresh shoots, and flower again in autumn up to Christmas in a greenhouse with a temperature of from 40° to 45°.

Nice plants may be obtained at most nurseries, many of them in a flowering state; indeed it is not practicable to grow grafted plants without flowering.

I may say that the Sweet Jasmine succeeds admirably in the same way. Grafted plants are best for pots, though others answer well, only they are more liable to put out long shoots, which should be stopped at the third or fourth joint, being careful to retain the short-jointed flowering parts.—G. ABBEY.

A FEW APPLES, PEARS, AND PLUMS FOR SMALL GARDENS.

PEARS.—1, Beurré Bachelier, December; 2, Bergamotte d'Espéren, March; 3, Beurré d'Amanlis, September; 4, Beurré Hardy, November; 5, Beurré Superfin, October; 6, Williams' Bon Chrétien, September; 7, Doyenné du Comice, November and December; 8, Joséphine de Malines, February and March; 9, Louise Bonne of Jersey, September and October; 10, Madame Treve, August and September; 11, Winter Nelis, January; 12, Olivier de Serres, March and April.

The above are all of first-rate quality, and bear in the west, south, and south-east of England freely as bushes and pyramids when grafted on the Quince stock.

APPLES.—*Kitchen*—1, Blenheim Orange, November; 2, Cox's Pomona, December; 3, Dunelov's Seedling, March; 4, Gooseberry Apple, May; 5, Hawthornden, August to November; 6, New or Winter Hawthornden, January; 7, Rymer, December to April; 8, Small's Admirable, December; 9, Lord Suffield, October; 10, Warner's King, very large, November.

APPLES.—*Dessert*—1, Cox's Orange Pippin, November; 2, Duke of Devonshire, February; 3, Early Harvest, August; 4, Keddlstone Pippin, March; 5, Lodgemore Nonpareil, April and May; 6, Melon Apple, December and January; 7, American Mother, October; 8, Pittsston Pineapple, December; 9, Reinette Van Mous, January; 10, Reinette du

Canada, April; 11, Sturmer Pippin; 12, White Nonpareil, March.

All the above bear well as dwarfs and pyramids on the English Paradise stock, no matter what kind, for all the Paradise stocks root freely on the surface, and form prolific trees. The French Paradise forms very dwarf trees; for pots or very small gardens they are really curious and pretty, as trees here in 4-inch pots are like Japanese trees, so full are they of blossom-buds. In France this stock requires a heavy tenacious soil, as the heat is apt to scorch their roots, always near the surface.

PLUMS.—*Kitchen*—1, Victoria; 2, Autumn Compôte, which succeeds it, and is much like it, but better; 3, Prinée Eglebert, large and rich; 4, Belle de Septembre, very late and large; 5, Early Rivers or Early Prolific, July and August. This is the most abundant bearer of all Plums, and, indeed, the best culinary Plum known, for preserved without sugar it retains its exquisite flavour for a year or more (I enclose my wife's receipt, see page 342—it is very old—for preserving Plums without sugar; it seldom or never fails if the bottles or jars are placed in a dry room). 6, Oullins' Golden Gage, very large, early in August, excellent for preserving, a great bearer. The tree is almost too vigorous for a small garden; as a standard it is a giant—a standard tree here ten years old bore six bushels of large fruit. 7, Mirabelle, as a bush only; this charming little yellow Plum is largely used in the east of France for jam and preserving; its perfume is *sui generis* and exquisite. 8, Early Orleans, early, and a great bearer.

PLUMS.—*Dessert*—1, Angelina Burdett, hardy and excellent; 2, Belgian Parole, earlier than the preceding, good for both purposes; 3, Jefferson, large and good; 4, Bonnet d'Évêque, one of the latest, hardest, and richest of Plums; its fruit, of a bright purple, are still (October 18th) on the trees quite hard, yet juicy and rich; 5, Transparent Gage, the most noble Plum known; 6, Boddart's Green Gage; 7, Early Green Gage; 8, Reine Claude de Bavay, one of the finest of Gage Plums, very hardy and late.

All the Plums I have mentioned are perfectly hardy, and will bear well as bushes and pyramids in districts south of the Trent, and even farther north in sheltered places. I have thus far complied with Mr. Abbey's request. There are, doubtless, many kinds as good as those I have mentioned, but I have given, according to my experience, the names of varieties that everyone may plant with safety.—THOS. RIVERS.

ROOT-PRUNING FRUIT TREES.

OVER-LUXURIANT trees being benefited by this operation, and this being the season for so treating them, I would ask for more attention to it. I am well aware that it takes time to root-prune in a proper manner, but it is not an annual operation needed by each tree. As many of the trees as can be root-pruned in a year should be so treated, and then by working systematically the whole may be compelled to grow in the manner the cultivator requires.

In root-pruning, by cutting hard back the coarse roots which supply the tree with an excess of sap, a number of fibrous roots will be formed, these being the kind required to produce fruitful wood. In doing this, care is necessary lest the fibrous roots already in existence get damaged, as injury to them would most assuredly debilitate the tree operated upon. The points of all damaged roots must be pruned back to where they are sound, in order to encourage young roots; but there are often cases in which the whole of the tree is growing too rank, through over-rich borders, or neglecting to cut back the runaway roots at their origin, and these will require careful lifting, digging a deep trench around them, and working the soil away from the roots with a steel fork. The soil should be moist, so as to separate readily from the roots, or these will be lacerated. Let the soil be thrown out of the trench as the roots are freed from it, keeping the ball undermined so as to get easily at the pert pendicular roots, which must be shortened back and spread out horizontally when the tree is replanted.

With respect to young trees, it is by far the best plan to lift and replant them every second or third year. By this means, with the judicious use of the pruning knife among the roots, fruitful trees, with an abundance of healthy fibrous roots will be produced; and if a few of the trees are found weak, some fresh loam can be added at the time of replanting. Any coarse shoots, which will usually be found unripe, will be best wholly removed. As the trees become older, lifting them entirely will not be necessary very often, but on the appearance of any gross shoots in the growing season these can be frequently

pinched back; and in the following autumn, before the leaves have fallen, it will be well to open a trench round them at a good distance from the base of the tree, and sever all runaway coarse roots with a clean cut, refilling the trench with fresh soil when obtainable. As the trees become thoroughly established, their

roots having ramified in all directions—as far, in fact, as their powers of extension permit, very little manipulation will keep them in order. Being healthy their fruitfulness will increase with age, and nerve the cultivator to the continued study of Nature's ways.—T. C. SAGE.

GROUND LEVELLING AND PRACTICAL GARDEN PLOTTING.—No. 2.
DRAWING PLANS.

THE first thing required is a case of mathematical instruments, which generally contains a pair of large compasses, provided with shifting legs—viz., the steel, the pencil, and the inking legs (the latter two are used for describing large circles in pencil or ink, and the steel leg for dividing lines and measuring distances accurately); a drawing pen for drawing straight lines in ink; a bow pencil; and a bow pen. The use of the bow pencil is to draw small circles, and the bow pen repeats the pencil work in ink. The ink used should be Indian ink, and should be put between the nibs with a camel-hair brush. Before drawing a line in ink try the pen on another piece of paper, in order to ascertain if the line is thick enough or too thick; if not right, adjust the pen by means of the screw. Before putting the pens away pass a piece of blotting paper between the nibs, so as to clear away the ink. The case also contains a rule with a bevelled edge to use when inking lines. The bevel must be turned downwards; this will prevent the work being smeared.

To Construct a Scale of Equal Parts (fig. 4).—Let it be required to construct a scale of 8 feet to the inch, which is the first scale I have used in these notes. A scale of 8 feet to the inch means that 1 inch on paper represents 8 feet on the ground. Draw a line of any length, and divide it into inches; divide the first inch on the left-hand side into eight equal parts, each part representing 1 foot. If 8 feet are required, put one end of the compasses or dividers down on point 8, extend the other end to point 0, which is 1 inch, and represents 8 feet. If 9 feet are required, extend the dividers to the first division of the divided inch on the left-hand side of 0. If 10 feet are required, extend the dividers to the second division, and so on. If 16 feet are required, put one end of the dividers down on point 16, and extend the other end to point 0, which distance is 2 inches, and represents 16 feet. If 17 feet are required, extend the dividers to the first division as before.

By dividing one of the eight divisions shown into twelve equal parts, each part will represent 1 inch.

In drawing a plan that is required to be transferred to the ground, it is safer to take the scale from a rule which has different scales marked on it and is generally supplied with the case of instruments, as by constantly applying the dividers to the paper the holes pricked by the points will get larger and lead to confusion.

The next three scales used in these notes are 12, 16, and 24 feet to the inch. All three are applied as the above; but it will be manifest the more feet there are to the inch, the more space the design will occupy on the ground.

A Drawing Board is necessary, also a T square, as shown. The drawing board should be about 2 feet long, and 18 inches wide; it must be smooth, flat, and perfectly square. On this board the paper on which the drawing is to be made should be properly fastened, which is done by pasting the edges of the paper to the board. This is only necessary when the work is likely to take some considerable time; for such exercises as

are contained in these notes it will be sufficient to fasten the paper down by means of drawing pins.

The T Square (a, fig. 5), is used to square that portion of the paper on which the plan is to be drawn, also to draw parallel lines and erect perpendicular lines; but in

Fig. 4.

case the board is not perfectly square, the T square should be worked against the left-hand edge of the board only—that is, to draw horizontal lines. All perpendicular lines are best drawn by placing the set square or triangle (b, fig. 5) against the T square, as shown; by so doing the lines will be at right angles to each other. All drawings should be first made in pencil, and afterwards traced in ink. The drawings may be cleaned, or faintly increased, with a piece of Indian rubber or stale bread.—M. O'DONNELL, Gardener to J. E. Leeming, Esq., Spring Grove Richmond.

Fig. 5.

LINARIA CYMBALARIA.

THIS pretty little native plant, called by some the Ivy-leaved Snapdragon and by others the Ivy-leaved Toad Flax, which I think is the correct name, presents such a fanciful and pleasing appearance in its natural state, as to be worthy of special notice;

for when a plant possesses, as this Linaria does, such valuable qualities as hardness, handsome foliage, dwarf habit, and free flowering, combined with very little or no difficulty in its cultivation, it is a matter of regret that it should not be more

frequently used for the purposes for which it is best adapted. These are the covering of such old walls as are becoming unsightly through decay, or where it is difficult to get any other plant to establish itself, and for planting in the alpine or rock-work garden. In either of these positions it may be most advantageously and easily used, and its trailing branches of Ivy-like foliage thickly set with bluish purple flowers, make it a subject to be admired by most people during the autumn and winter months, when it is most attractive and serviceable.

I have sometimes seen this plant growing in little tufts on walls that have deciduous plants trained against them, so that in winter, when the plants have shed their foliage, it very effectually hides their naked stems, and at the same time clothes the bare wall to a great extent. Again, where it is necessary to have elevated rough stone edgings to garden walks, this little British plant will be found one of the best to grow there, and its delicate branches, when trailing over the stones, are sure to please.

Lunaria Cymbalaria reproduces itself very freely from seeds, and where any of them can effect a lodgement it will be sure to germinate when a favourable time arrives. It is difficult to induce it to establish itself very near walls or smooth surfaces, but where a thimbleful of earth can be deposited, and moisture retained in it, that difficulty passes. In very heavy retentive soils the plant does not thrive so well; therefore, if it be desired to plant it where such a soil prevails, fully 50 per cent. of old mortar rubbish must be added, and the plants will be found to succeed well, especially if the position is elevated.—Tnos. RECORD, *Hatfield Park*.

PEAS IN 1870.

WITH me this has been the most extraordinary year on record for heavy crops of Peas, and I believe one of the chief reasons has been the treatment given. Peas, like many other things, require good cultivation, otherwise they tell tales.

My treatment is as follows:—In January or February I trench the ground to the depth of 3 feet, giving a liberal dressing of manure and quicklime, for I consider it is the deep cultivation which is the great secret of successful Pea-growing. With me the hotter and drier the summer the more luxuriant are the Peas and the drier the produce, the heat causing the roots to strike farther into the ground; and there being plenty of room for them to run, and plenty of manure to feed on, the crop cannot but do well, and thus success is insured. Up to October there was not the least indication of mildew. Mildew is a sure sign, either of the ground being poor, or there not being depth for the roots; then, owing to there not being many roots, or from these being unable to penetrate into the soil to a sufficient depth, the plants suffer from the sun. Defective drainage is another cause. I have seen Peas in perfection, and after a week of sudden heat they have been a failure owing to the above reasons.

I do not sow the first Peas till March, as I find they come in as early as those sown in November, besides bearing a much better crop. The birds and mice always make great havoc among Peas that remain in the ground so long. I give plenty of room—9 feet from row to row, planting Cauliflowers, Brussels Sprouts, and Winter Greens between; and I find this tends to prolong the gathering season, the intermediate crops helping to keep the roots cool, and yet not keeping the sun from doing its duty to the tops. I should add my kitchen garden is in first-rate condition, being very rich and well drained.

I grew this season twelve varieties. The first, Ringleader, was gathered June 18th; the last, Veitch's Perfection, on September 30th for dishes, and for soups a week later, thus giving a period of fifteen weeks for the use of this delicious vegetable. During the fifteen weeks the gatherings averaged three per week at least. Peas, where practicable, should be grown on different ground every year.

I will now take the different varieties in the order in which they were gathered:—First, Sutton's Ringleader, gathered June 18th; this is the earliest and best-flavoured kind with me, is very prolific, and 10 lb pods and peas are the largest of the first early sorts. This attains the height of 3 feet 6 inches. Next comes Carter's First Crop, gathered June 24th. This is a very useful Pea, but smaller than Ringleader, and not so tall by a foot. These are the only two of the first early I intend growing next season. I had both Dillistone's Early Prolific and Sangster's No. 1, but they are inferior to the two named. Advancer is a good Pea, coming in a few days later than Carter's First Crop. I also sowed this in the middle of June, and it came in

very useful in September. Laxton's Prolific Longpod came in during the first week of July. This is, as it is named, prolific, but when it came to be cooked it was the worst-flavoured Pea of the season. I was never more disappointed.

I now come to one of the best of Peas, Beck's Prizetaker, which I began gathering in the second week of July. This is undoubtedly one of the best varieties grown; its flavour is delicious, it is an extraordinary bearer, and it continues long in yield. Champion of England followed the week after; this well retains its reputation as being the best flavoured of the summer Peas. It is also an excellent cropper, and is a good companion to Beck's Prizetaker, the height of both being about the same, 6 feet. Maclean's Wonderful is excellent, and its height being only 3 feet, it ought to be more grown, for it is a first-class Pea and very prolific. This brings me to the end of July or beginning of August.

Harrison's Glory came next in rotation, but as it has now only done moderately well for two years, I must discard it. To Ne Plus Ultra I recommend every one to give a trial, for, taking into account its flavour, its productiveness, and the length of time it remains in good bearing, it is unrivalled. This came in at the middle of August. Prince of Wales is well worth growing as a late Pea, though it gives way to the next and last on my list, Veitch's Perfection. I made two sowings of this; the first came in during the third week in August, the second in the first week in September, and I gathered till September 30th. As a fine-flavoured late Pea, there is nothing to equal this.

In conclusion I will give a list of the varieties which proved best this year. I scarcely know whether for midsummer use Champion of England, Ne Plus Ultra, or Beck's Prizetaker takes the lead, but I rather incline to Ne Plus Ultra. Of the early varieties Ringleader stands by itself; Maclean's Wonderful follows; then Ne Plus Ultra, Prince of Wales, Advancer, and last of all, and best of the latest, is Veitch's Perfection. This list I am quite aware contains none of the new kinds of which so much is said, and which I hope this next season to grow, but is composed of what may be considered old standards.—STEPHEN CASTLE, *Bent Hill Gardens, Prestwich*.

THE ECKLINVILLE SEEDLING APPLE.

WE have been informed by Messrs. Dickson & Son, nurserymen, Newtonards, near Belfast, that the Apple we referred to lately as Eckland Vale should be called Ecklinville. It was raised at Ecklinville, near Belfast, by a Scotch gardener named Logan, along with another dessert Apple named Logan's Seedling. Both of these Apples are of good quality, and to be found in the nurseries in Ireland.

We have another communication relative to the same Apple, from Messrs. Irvine & Son, nurserymen and seedsmen, Ayr. They say—"The Ecklinville Apple is well known in this district, and has been extensively propagated by us for upwards of twenty years. We obtained it of a neighbour, who had it from Mr. McInachan, gardener at Ecklinville, and its many good qualities, especially as a baking Apple, have made it a general favourite here."

We have third letter on the same Apple. It is the following—"It is some ten or more years since I received this kind of Apple from Ireland, under the above name. I have it now before me, with Small's Admirable and Stirling Castle Pippin, and have just tasted them. The Ecklinville has tender flesh, is juicy, and the most acid of the three. Next to this in pleasant acidity is the Stirling Castle. Small's Admirable is not sweet, but more so than the others. As to their appearance, they are so much alike as not to be distinguished even by a good judge. The Ecklinville has numerous small brown specks on its skin; the other two are quite clear, and are handsomer fruit than it. This may, however, be accidental. They are all three of dwarf habit, and most abundantly fruitful. The Stirling Castle is more upright in growth than the Admirable, and this is a distinguishing point, the only one, in its character."—T. R.

POTATOES.

I WAS never more forcibly struck by the utter impossibility of laying down any positive statements on the subject of Potatoes, than by reading the short account of your correspondent "M. H.," October 13th, page 287, concerning the Lapstone. I have ever maintained that in point of flavour and general excellence it is the best of all Potatoes, but I have at the same

time always deplored its great fault—viz., its delicacy of constitution, and I have never considered it a large cropper. This year has so completely confirmed my opinion, that I felt almost inclined to say I must only grow a very few Lapstones for the future. I grew thirty-six sorts—of these more anon—and of all the thirty-six the Lapstone was the most diseased; all the finest tubers were bad, and I should think that at least three-eighths of the crop went. I may say that I grew it in two situations—in my garden, and in a pasture which had not been turned up for a great many years, and which had not a particle of manure; that I took up one half of the crop in August and the other half in September, and that both were equally attacked by disease. How, then, can we account for the different experience of "M. H." and myself? and is it not hopeless to lay down any positive statement? Or can it be that "M. H." grew the Lapstone at all? He says, "Haigh's or Lapstone Kidney." There is a Haigh's Kidney as well as the Lapstone, and I believe it is less liable to disease. This may be the solution.

I see in the interesting account of Admiral Hornby's Potato produce that Dawe's Mitchless and Webb's Imperial are set down as giving different amounts of produce, but I have always believed them to be the same. If I am correct it will rather detract from the value of the return.—D., Deal.

The remarks of Mr. G. Abbey on Potatoes, in your number of October 13th, are very interesting and instructive. As a grower on a moderate scale, I can supplement his paper by one or two words on the mode I adopt, and which has been this year particularly successful. I always have the rows of Potatoes planted, as far as possible, due north and south. This lets in the full sun between the rows. The tubers were planted rather deeply to avoid the necessity of earthing-up. As soon as the stems appeared the rows were flat-hoed, and all the weeds carefully raked off the ground. The only attention they had afterwards was as follows:—A light boy of about eleven years of age passed along the rows, treading as little as possible, and pulled up every weed by the roots, putting them as he went along into a little basket which he carried on his arm. This was repeated several times. The consequence was that the ground was kept thoroughly clean, and the remaining fibres of the tubers undisturbed. I had a magnificent crop, and also got rid of many basketsful of weeds.

The kinds I grew were Alma, Paterson's Victoria, and the Pink-eyed Fluke from Scotland. Of the second kind the haulms were from 6 to 7 feet high, but the produce was marvellous.

I think the manure ought not to be put in too green. It should have passed through the first stage of decay, and be forked-in during November. The soil will take up all the matter suitable for the food of the tubers, and the benefit will be secured for after-crops.

A boy or girl kept at Potato-weeding will do great service, and may be had for about 1s. 6d. per-week.—F. H. POLTER, Cheltenham.

GLAZING AND PAINTING GARDEN STRUCTURES.

I WOULD as a matter of choice paint the outside of glass houses once every year; I should thus have them always neat and clean, and avoid the trouble of scraping and scratching. When sashes have been long neglected there must be a cleaning and reputting before there can be any painting. On the one-coat-every-year system I hardly know how long good putty would last, as it would not have a chance to crack and let the moisture in. Only let it crack from the wood, and it soon becomes needless. Late in autumn, if the weather is fine, I consider is the best time for all such work, as putty and paint dry more slowly, but more firmly, and without cracks.

As a rule, I wish every trade to keep to itself and to do its own work, and then generally the work will be better done. But in many places there is often much rough work of this kind, which, if done at all, must be done by the garden men at the most suitable time, and when the glass, however bad, cannot be spared in quantity sufficient to keep painters regularly at work. I lately saw, if something were not done, the winds and moving the sashes would throw out the glass from want of fastening. I have a lot of old sashes that have been useful for many years for laying over earth pits, and which I was allowed to keep on the clear understanding that they were never to involve a glazier's or a painter's bill. In doing similar work

I had this great advantage over tradesmen, that my men could work out of doors only when the weather was suitable, though I had taken the precaution to have many of the worst sashes washed and brought under cover before the rains came on.

Many people think that anybody can handle a putty knife or a paint-brush, just as they imagine that anyone can without trouble master all the details of gardening. There are others who wish to help themselves and yet feel no such confidence, and to them the following simple practical details may be useful.

Before painting it is important that glass and woodwork should be clean, even if a good washing should be necessary. In replacing even a square or two of broken glass, the old putty should be cleanly cut out, and a little thin paint run along the rest of the sashbar before the putty is bedded, allowing the paint to dry a little. With regard to moveable sashes in bad order, where the putty has mostly perished, it is often not possible to wash both sides of the glass without the squares falling out and being broken. It is then best to clear away all the loose putty, take out all the glass thus loose, wash it in a pail, and set it to dry. Wash the sash then, cut out all the putty at all gone, leaving only what is hard and firm, and when the wood is dry run a paint-brush along the sides of the bare, and in less than a day it will generally be fit for glazing. In all reglazing this thin coat of paint on the sides and rest of the sashbar is of great importance, as the putty is thus more firmly joined to the wood. This is often neglected. Even in glazing new sashes I would rather have the paint under instead of over-dried.

Then as to putty. The best is made of the best linseed oil and the best ground whiting, and the longer it is made, and turned, and sweated in a heap, the better it will be. For common purposes it is best to purchase it by the hundredweight. I prefer it stiff instead of soft. When it becomes rather stiff for working, it is better to beat it and work it well instead of adding more oil to it. When warmed by beating and kneading it works well and smoothly with the knife, and there is little or no sticking to the fingers, and, what is better, the putty sets well and dries more quickly and regularly than if softened with more oil. For certain purposes I have had a little white lead mixed with the putty; but though this makes it harder, there are two inconveniences attending it—first, it is more apt to crack than good wrought putty alone; and then, again, if you have to move it afterwards, there is much more trouble in hacking it out. A good labourer soon learns to place the putty well and leave it smooth with the putty-knife, whilst the base must never go beyond the rest for the glass on the sashbar.

The lasting of the putty greatly depends on giving it and the wood one or more coats of painting as soon as the putty is sufficiently dry. If there are many sashes to do, by the time the last is glazed the first will be ready to paint. This time two years ago I had a large job, and, if not done, I should have expected the glass to have been everywhere after a windy night. I could do no more than give one coat of paint over the putty, but for the two years it has seemed as sound as a piece of wood. Observing, however, a few small cracks the other day, I have just run a paint-brush over it after washing the sashbars down, and that will keep all sound and secure.

After several years the atmosphere robs the paint of its preservative virtues, and this is one reason why I advocate one coat a-year instead of several coats after the mischief is done. Then as to paint. Nothing is better than white lead and oil, though it is next to impossible to get white lead genuine. The whiter the paint the more lasting it will be, if the lead is near the mark; but the whiter it is the more easily is it sullied, and therefore it is often desirable to tone it down a little to a light stone colour. For outside work I think it is a good plan to use a portion of anticorrosion with the paint. I imagine it stands better than paint alone or anticorrosion alone. I should not advocate anticorrosion for inside work, or where the paint was to be subjected to much washing, as then lead paint is smoother, and stands the cloth or the brush better. For orchard-house work it would do either inside or outside. The very roughness outside makes it more enduring. It is thus less influenced by heat and cold than a smooth surface, just like a piece of rough-surfaced ground contrasted with one that is smooth and firm. A number of years ago I painted two posts with stone-coloured lead-oil paint in the usual way, but whilst one was wet I threw over it as much fine light-coloured sand as it would take on. In three years the painted post had the paint cracking and peeling; the sanded paint did not exhibit a flaw after four years, but looked more like stone than wood

Had I much to do with anticorrosion paint, from all I have seen and learned I would apply for Carson's anticorrosion, which is to be had of all shades of colour.

The very best paint I have seen for standing was made of zinc and oil. I have heard little of it of late. One thing against it was, it strained the wrists and arms of the painters in wielding the brush, as it worked so stiffly. The anticorrosion paint, even if good, is easily put on; but there is a precaution to be taken when it is used by itself or in conjunction with lead paint, and that is not to have too much in the paint-pot at a time, and to stir it frequently with a stick. For reasons assigned above, for clean dry walls and woodwork out of doors I would prefer anticorrosion to lead paint. I will add one more caution to the inexperienced as respects garden sashes, and that is to use a small brush for the putty part of the sashbars, and, if new, to tie it firmly across about 1 inch or less from the point, to prevent the paint going on the glass. Even with that care it will be well to have a soft rag to wipe off any little drop that may get there. Be very careful, especially with all lead paints, that none is allowed to get in and remain about the finger-nails.

Some of your readers may say, Why all this to-do about putting and painting, when, by using metal that cannot rust, and grooves or packing for glass, there will be no need for paint or putty? Why, indeed, if all who take a pride in their gardens, and would rather see their garden frames and sashes neat and serviceable, instead of little better than sieves, for keeping out water—if all such could at once adopt such new improvements. With every wish for improvements, a good many of us must make the best of very common, rather unsemitable materials; and if the best is made of them, the results are often anything but despicable. Sometime ago a great lover of Auriculas was sadly vexed that some of his best plants damped so in winter, though he had them near the glass in a nice two-light box, in which not a single square was broken, and air was given freely back and front. The squares, like a good many old-fashioned lights, were rather small, but that was not the cause of the mischief. Though the glass stood better than could be expected, the putty was nearly gone, and the rest loose at the sashbar, and at every drizzling rain or even very heavy dew there was drip all along the sashbars over the favourite plants beneath, one of those things of which the Auricula is particularly impatient. I could call to mind many instances where Pines have been spoiled and late Grapes damped from the drip from wasted putty; and whilst such glazing exists means must be taken to stop such dripping and secure the glass. I have omitted to say that moveable sashes can be best painted when off, two men to a sash, and the sash set up on its side, so that one side of the sashbars can all be painted, and then the under side of the sash placed at the top side, so as to paint the other side of the bars. The work can thus be done much more quickly.

Washing glass, woodwork, and walls is a great job with us in the end of October and the beginning of November. A little dullness of the glass is often desirable in summer where regular shading is not forthcoming. I use little shading but whitening put on for temporary purposes, as mere whitened water, or mixed with milk and size when I wish it to be more permanent. This whitening does no harm to paint or putty; but some use lime instead, and if that is at all quick it will injure both. All these, and all dullness and green spots in glass, it is desirable to get rid of before the dark days of winter are on us; then the glass cannot be too clean.

For outside washing I find nothing better than clear soft water, heated a little if the weather is cold. The same does very well, or weak soap water, for the inside of sashes in places where no artificial heat has been used, and where no insects have appeared. In the case of sashes over pits, frames, &c., or over houses, where we cannot move them, and where the least trace of green fly, thrips, or red spider has appeared during the summer, I like to syringe the whole well with water at about 180°, and if soap is dissolved in it at the rate of not more than 1 oz. to three or four gallons all the better. There is not a cranny in sashbars, rafters, stages, back walls, &c., but forms a good nest for the eggs of insects. Much of security from insects in a following year will depend on all these little crannies and openings receiving a good forcible washing of hot water. Water at that heat can be applied with the syringe, with the help of a thick cloth over the syringe, so that the left hand can hold it freely. Of course, however near it is, the water will be cooler before reaching the crannies and walls. At such a temperature deciduous fruit trees that have lost their

leaves may be washed or syringed, and thus eggs of insects, as well as the insects themselves, may be destroyed. In lean-to houses, brick back walls and plastered walls are great refuges for insects and their eggs, and such remain dormant until the advancing heat brings them into active vitality. It is better than nothing to limewash these walls every season; but it is much better to wash them well with hot water and to wash off the old whitewashing before putting on the new. The fresher the lime for this purpose the better it will answer. The whiteness of a back wall will in most cases be no drawback in winter, as the white surface will reflect the light. Where lime alone would be too glaring, it could be toned down a good deal with a mixture of sulphur. When the sashes are rather steep, so as to catch the rays of the winter and spring sun rather direct, and tender plants are grown near the apex of the roof, it may be desirable to tone down the colour there considerably more, by adding a portion of lamp black, or even fine root, to the limewash. In either case you will fail to make a good uniform wash unless you make the sulphur and the dark colour fine, and then with a small quantity of water beat each up into a paste before mixing with the limewash; then there will be no difficulty. Without such a simple process of wetting and making into a paste, you will be able to mix neither well so as to get a uniform homogeneous colouring.

Merely as a matter of precaution and prevention, I adopt the above systems of washing in almost every change of crop, in wooden frames or brick pits. Lately I planted out strong Cucumber plants in a brick pit, but before doing so, glass, woodwork, and walls, were well syringed with hot water before fresh limewashing the walls. In this pit a few green fly had appeared twice during the season, and early in spring some Strawberry plants near the apex had a few red spider. A little care now will often save much smoking and washing afterwards.

There is another preventive method I sometimes resort to, and that is burning sulphur in such pits and frames when empty; then it can do no harm, but care must be taken that the fumes find their way to no other place where plants of any kind are growing. Sulphur may also be burnt in houses of deciduous fruit trees, such as Vines and Peaches, when the wood is ripe and the leaves falling or removed, but with great caution, as if the wood is at all green—not thoroughly ripened—the sulphur will do great injury. Even these fumes, strong as they are, will not kill everything. I know of a small house thus smoked twice in order to destroy the mealy bug, but on taking up some shelves there the insects were quite jolly between the shelf and the bearers, though the interstices were large enough to let the sulphur vapour in. Exposing houses to frost would kill many insects, but I am not sure that the eggs would be destroyed, and I have known of some instances where mealy bug, notwithstanding its love for a high temperature, has, defended by its woolly coat, stood 10° below the freezing-point seemingly uninjured. I never knew it withstand water near the boiling point when forcibly applied.

At this dull season of the year much may be done by ensuring cleanliness, to act as a preventive against insects during the coming season, and thus labour and expense will alike be saved. In houses with earth floors an additional security is obtained by scraping away the surface, and sprinkling with hot water before surfacing with fresh soil.—R. FRIS.

BURR KNOT APPLES.

YOUR "CONSTANT READER," page 282, is right when he says that the Burr Knot Apple of the north is a good kitchen Apple, but wrong when he says that it does not resemble the English or any other Paradise stock, and he forgets, or does not know, that there is another Burr Knot, a still nearer relation of the Paradise, and which roots as freely from truncheons as its northern congener, which, I suppose, Dr Hogg did not think worthy of a place in a work upon select sorts, but he has in his "British Pomology" described both the Burr Knots.

I have obtained both kinds from suckers taken from stocks on which other sorts of Apple were grafted, and also several other varieties of so-called Paradise stocks; in fact, there are several sorts of Apple that resemble the Burr Knot and Oslin in their character, and that form roots from truncheons. Yet I may say that the rooting of Apples from cuttings is not a profitable way of procuring them. I have put in thousands by way of experiment, but have always had poor success with them in this way, and as far as I know, nurserymen generally prefer layering to trying cuttings. My own favourite Paradise

is, perhaps, the freest-rooting Apple known, and yet it does not pay to strike it from cuttings in the usual way, especially by trancheons. This last may be a good way for an amateur, but will not pay a nurseryman.—JOHN SCOTT, *Merriott Nurseries*.

OCTOBER CATERPILLARS.

Not all of the caterpillars which hibernate in our country continue to feed as long as leaves remain on the plants or trees to which they are attached. Some withdraw from their food quite early—that is to say, during September, be the weather what it may, and place themselves in the position which they intend to occupy until the face of Nature is again brightened with new foliage. Amongst these is the caterpillar of the elegant Geometer called the Grass Wave (*Aspilates strigillaria*), a species occurring on heaths in the south of England, and also in Ireland. The eggs are deposited by the parent moth, which is rather a rapid flyer, on or near the common Ling during July. The young caterpillars grow slowly and hibernate before winter arrives at the roots of their food-plant, feeding again in April. When touched or alarmed, this caterpillar falls from its position, and remains rigid as if dead. It is of a greyish-brown colour, varying in shade, with paler longitudinal stripes faintly marked. The whole body is covered with minute warts, which emit bristles; there are two humps on the ninth segment, and two of less size on the tenth; on the last segment there are two points, just above the anal claspers. The very handsome caterpillar of the Grey Mountain Carpet (*Larentia castata*) might be found young in October by those who are still making holiday in the north of England and in Scotland; and as the species is abundant where it occurs, the caterpillar should be more frequently found by observers; and the plant on which it feeds is not of difficult growth. At this time they are small; nor do they move until the spring, resting close to the roots of the Whortleberry or Bilberry; in April they reascend the twigs, but rest in the day with the head downwards. At night they turn round and feed, becoming soon mature. The body has a few small warts on each segment; the head is of an amber-brown, the general colour being reddish-brown or olive-green, the skin velvety; along the back there is a beautiful series of markings, arranged on seven of the segments, these are in the shape of the letter V, the point being towards the head; on the sides of this mark are four parallel lines on each segment; a fawn-coloured line runs through them all, the remainder of the V mark being filled up with rose colour; the lines are pale; there is a fold of the skin above the spiracles which is also pale. The legs are semi-transparent and pinkish. The cocoon is spun up amongst the twigs, and the moth comes forth at midsummer.

In October we find on the common Clematis (*Traveller's Joy*) the adult caterpillar of the Small Waved Umber (*Phibalapteryx vitalbata*). This rests, when not feeding, in a stick-like position, and might easily be passed by as an inanimate object; but if the plant be beaten into a net or umbrella, the caterpillar falls with the head bent downwards. The whole body is freckled over with warts, not apparently arranged in any method; the head is grey, with two small black spots on the mouth, and lines of the same colour on the cheeks; a narrow black stripe extends from the head to the tail, which is interrupted at each segment; the body generally is brown, getting paler towards the tail; along each side there is a wrinkled fold of the skin, lighter than the ground colour, and partially chequered with dark brown spots. This caterpillar becomes a chrysalis ere the winter sets in; and the moth, which appears in June, may be roused from the hedges by day if these be beaten near the food-plant, flying out usually with great rapidity. At night it visits the blossoms in search of honey. Abundant in some places, and scarce in others, is the moth known as the Clouded Magpie (*Abraxas ulmata*), and the caterpillar is to be found feeding until the end of autumn in woods on the yet remaining leaves of the Wych Elm. It is exceedingly torpid in its movements. Mr. Greene observes about its habits that "it does not appear to thrive in confinement. It seems to have the power of producing an almost unlimited quantity of silk. When disturbed it drops immediately. Give a tree where it occurs a tap with your stick, and down comes a whole shower of larvæ." The head and legs of this creature are deep black; down the centre of the back runs a black line, edged on each side by yellow. Beyond this is another broader stripe of black, then a white line, then another black line, and this again repeated. All these are distinctly defined. Just above the spiracles is a yellow

stripe, enclosing two black spots on each segment. The claspers and under surface of the body are dull yellow. The chrysalis is to be found sometimes by digging. Some of the small "looper" caterpillars, which produce the different species of moths commonly called the "Pugs," are yet feeding, and may even be found to the end of the month. All these caterpillars have a general resemblance to each other in their style of marking, though every species has its peculiarities, and the genus is also remarkable for the bright hues displayed on the chrysalis, especially as viewed by a moderate magnifying glass.

What is known as the Edinburgh Pug (*Eupithecia helvetica*), a species confined to Scotland, and unknown in England or Ireland, is produced from caterpillars which may be found full-fed about this time on the common Juniper. These individuals are rather short and "stumpy," of a grass-green colour, the dark line running down the centre of the back, which is tipped with purple; below this, on each side, are other lines of a deep green, sometimes edged with purple; just above the spiracles there is a wavy line of pale yellow; the head, which is slightly notched on the crown, is of a very deep purple. The moth is on the wing in May, and is very elegantly marked, surpassing many of its brethren in its display of colours. The caterpillar of the Pimpernel Pug (*Eupithecia pimpinellata*), dwells on the Burnet Saxifrage, making havoc of the flowers and seeds of this plant. There are two distinct varieties of this caterpillar, which, unlike the last, is long and slender. One form is green, with three purple lines, two of which are very faint; along the spiracles a yellowish line, the head and claspers being purple. Upon the back there are a few scattered tubercles. The other variety is of a general purple, with two lines almost black passing along each side of the body from head to tail. Mr. Crawe observes that these caterpillars seek those plants in preference which grow by the sides of hedges. He notes also that they are so infested with parasitic enemies that hardly one in ten attains its proper growth and becomes a chrysalis. This is placed beneath the surface of the earth. There appear to be two broods produced yearly.

The extraordinary caterpillar of the Lobster Moth (*Stauropus Fagi*), though not of very large proportions, may fairly take rank as the most singular in conformation of all British caterpillars known to collectors. The species derives its Latin name from the Beech, yet it seems more particularly connected with the Oak and Birch. It is rare, occurring only occasionally in the south of England, where sometimes an entomologist, taking a survey of the partially bare trees, chances to discover a "Lobster," grotesquely perched on some twig, and is in rapture with his prize, which dies, perhaps, on his hands thereafter, since caterpillar-breeding knows many mishaps. When reposing, this caterpillar throws back the head, and raises the front segments; the hinder part of the body is also raised, and bent towards the head. This is as large as the three segments behind it; each division of the segments shows very clearly, and from the fifth to the tenth there are two humps on each segment, decreasing in size towards the anal extremity; on the last segment there are two erect rigid horns. The first pair of legs are of average size, the second and third pair are of extraordinary length. The colour of the body is a dull brown; there is a very narrow pale stripe down the centre of the back, with a stripe on each side of it of a black hue; there are numerous points scattered over the surface, giving the caterpillar a shagreened appearance. Allied to this species, as also belonging to the family of the Cuspidates, is the Coxcomb Prominent (*Notodonta casmelina*) which feeds upon Oak, Birch, Nut, and other trees. It usually rests with the anal extremity raised from the surface of the twig or leaf, and if alarmed, will then throw back the head, and open its jaws, remaining in this position for some time. At the tail of this caterpillar are two warts or protuberances, with pink tips, and a little cluster of bristles proceeding from them, and there are scattered black bristles on other parts of the body. The ground colour is a pale green, almost white on each side of a stripe which passes down the back from the third segment to the extremity of the body, of a bluish tint, and slender. Near the spiracles there is a series of white spots; these are connected by a number of very faint lines. The legs and claspers are pinkish. The cocoon is spun upon the surface of the earth, composed of a little silk, mixed with particles of earth or dried leaves. A second brood of the Chinese Character (*Cilex spinula*), feeds upon the Hawthorn in most of our hedges in September and October. The caterpillar of the Pale Prominent (*Pilodontis palpalis*), which occurs full fed now on Willow, Sallow, and Poplar, unlike many of its brethren, has no humps or hairs.

The head is small, of a pale green; the body of the same colour, slightly rough with wrinkles; six slender stripes of white run from head to tail; on each side, above the spiracles, is a very distinct yellow stripe edged with black; on the second and third segments there is a little patch of lilac close to this stripe. The cocoon, from the locality where the caterpillar usually feeds, is often placed near the edge of some rivulet or pond, and the insect is careful to select a spot as dry as possible, and above the water-level, so as to be in less danger of being washed away in any overflow. Both the chrysalis and the caterpillar of the Pebble Hook-tip (*P. falcula*), may be detected on the Birch in October in various parts of England. These are individuals of the second brood, producing moths in May. The most remarkable circumstance connected with the appearance of this caterpillar is the variety of warts which are arranged along the back, some being small, others large and nipple-shaped; from each of these latter there arises a circle of short brown hairs, with a long bristle in the centre. The head is a greyish-green, with two bars on the crown. The body generally is pale green, with some purplish markings, part of these clustering so as to form a tolerably well-defined stripe down the back.

The caterpillars of certain of our Egger moths, which have to pass the winter in that preliminary stage, will occasionally feed through part of October, and may be seen, during high winds, crawling with great rapidity across a field or road, having been dislodged from their food-plant. The Oak Egger (*Lasiocampa Quercus*), is produced from a large caterpillar, which is about three-parts grown ere the close of autumn, and then ceases to feed until spring. The young caterpillar is brown, afterwards it becomes of a velvety black, though clothed thickly with brown hairs, which are of two lengths. There is a white mark, in the form of a crescent, on the side of the third and fourth segments; along the centre of the back there is an interrupted white line, and a similar one on each side. Unless much annoyed, the caterpillar of the Oak Egger does not roll itself into a ball. On heaths near London, and many other places, the caterpillar of the Fox Moth (*L. Rubi*) is found in autumn and spring; it is difficult to keep through the winter, unless it be placed on a sod dug from its habitat. This much resembles the preceding, but the hairs are more velvety, and of a rich brown; the sides appear entirely black. When forming its cocoon the hairs are freely stripped off, and mingled with silk; this is very loose, being 3 inches or 4 inches in length.—(*English Mechanic and World of Science.*)

PORTRAIT OF MR. RIVERS.

The following subscriptions to Mr. Rivers's portrait have been received. We again repeat that the whole of these subscriptions are forwarded voluntarily; and we trust that all who appreciate Mr. Rivers for the useful work he has done will not postpone sending their subscriptions in expectation of a direct application being made to them, as no such mode of solicitation will be resorted to.

ROYAL HORTICULTURAL SOCIETY'S GARDENERS' EXAMINATIONS.

The following are the results of the gardeners' examinations on July 12th:—

1. G. Haskins, Royal Horticultural Society, Chiswick.—Third-class certificate with 700 marks in Fruit and Vegetable culture, and second-class with 830 marks in Floriculture.

2. C. Burley, Royal Horticultural Society, Chiswick.—Third-class certificate with 570 marks in Fruit and Vegetable culture, and second-class with 770 marks in Floriculture.

3. W. Mitchell, Royal Horticultural Society, Chiswick.—Not passed in Fruit and Vegetable culture, and second-class with 840 marks in Floriculture.

The examiner in Fruit and Vegetable culture remarks that "these were very unsatisfactory papers." The examiner in Floriculture remarks that "the best answers were those of No. 2, but fewer of the questions were replied to."

PEARS.

PERMIT me to make a few observations upon the three Pears described at page 284—viz., the BELLE ROUENNAISE, AVOCAT ALLARD, and HELIOTE DUNDAS. Of the first, it is said that it ripens in October. I have grown it for the last ten years, and have always found it ripen in August.

Of the second I enclose a tracing taken from a fruit which ripened here October 4th. The fruit this season is very small; last year it was twice the size, but I did not keep a tracing of it. Skin lemon yellow, much spotted and marbled with russet. Stalk about 1 inch long, set upright in continuation of the

Avocat Allard.

fruit. Eye deeply sunk in an even basin. Flesh yellowish-white and melting. Juice very abundant, rich, spicy, and very delicious. I send you this description, as I have never seen one of it, excepting some slight remarks of M. Liron d'Airoles, in his "Liste Synonymique."

The third is Heliote Dundas. My note of this handsome fruit, made in 1869, says—delicious, rich, and buttery, but not over-juicy, ripe October 1st. This is a Belgian variety, said to have been raised by Van Mons, and it seems to have improved in this country, as in Belgium it is said to have breaking flesh, dry, and gritty, slightly sugary, and without flavour, with insufficient juice. 1869 and 1870 have been both warm seasons, and here it has been good, but in a cold or wet season it would be as it is in Belgium. It might be improved by planting against a wall.

I have just been tasting Doyenné du Comice from a Quince, and General Toddleben from a Pear stock, both are extra first-rate. The Doyenné from a Pear stock is as highly flavoured, but not half the size as from a Quince.—J. Scott, Merriott Nurseries.

AGARICUS PROCERUS.

I WAS lately at an hotel at Malvern, and finding in the garden a remarkably fine specimen of *Agaricus procerus*, I directed the waiter to have it cooked. In a short time he returned to inform me that it was poison; next, a message came from the French cook repeating the same tale; and before I could get it broiled, I had a third remonstrance. The number of my room was asked, so that if a body had been found there in the morning it would have been identified. I need not add that the fungus was delicious, and that, much to the astonishment

of the waiters, I survived the dish. I will not say, as Swift would have done—

"They'd rather have that I should die,
Than their predictions prove a lie."

But though I recommend my readers to eat Agaricus procerus when they are lucky enough to get hold of it, yet I do not recommend them to do so at an inn, for, on second thoughts, I did wrong in having the fungus cooked there. It might have happened that I was taken ill from some cause quite unconnected with the banquet, but the landlord would certainly have been accused by the public of having served up poisonous Mushrooms to a guest. Scandalous rumours find ready belief.

This autumn I have eaten with much pleasure Agaricus comatus in its young state, while the gills were still white—G. S.

FRUIT TREE NAMING.

IN the first notices to correspondents, page 251, the Editors prefer a well-grounded complaint. They had received, for the purpose of giving names, no less than three baskets of Apples, respectively containing twenty-nine, twenty-three, and seventeen sorts. Imagine a person sending twenty-nine Apples at one time! Who is to blame for such a proceeding? I most unhesitatingly affirm provincial nurserymen and gardeners. And why? many of them will be apt to exclaim. The following, I hope, will serve to show.

First, as to gardeners. When fruit trees are received from a nursery the tallies attached to them are of the slimmest description, being made of a narrow strip of wood tied to a stem or a branch by a small piece of string. The wood decays, the string rots, the tally disappears; it has dropped to the ground, and been either dug into the soil or raked off with the leaves and weeds to the rubbish heap: or, if by good fortune it may have been refastened, it has only been to escape its ultimate fate by a season, or to hang on the tree till it becomes undecipherable. Nurserymen's tallies ought to be regarded as merely temporary, to be replaced by a durable article at the earliest convenience. An excellent material is zinc, possessing lightness, cheapness, and durability. Let the name be written with indelible ink (say Yeats's), by a quill, and the label suspended from the tree by copper or lead wire, and it will last for generations. At the pruning or fruit-gathering seasons, a glance will show whether the wire is cutting the bark or not; then a minute or two, owing to the pliability of the wire, will suffice to rectify the matter; or, as recommended by Mr. Rivers, the names, in the case of wall trees, could be nailed to the walls, either above or beside the trees. I know one garden where this is practised; the names being on a level with the eye, and painted in letters sufficiently large that one passing along the walk can read at a glance.

Another method is occasionally adopted by some gardeners, but to it there are grave objections. The names of the trees are written in a book in the same order as they are planted, but the book is locked upon as private property, and the gardener when leaving the place takes the book with him. How, then, is his successor to learn the names of his Apples or Pears? for remember, pomological knowledge is not so very extensively disseminated that the general run of gardeners know a great variety of fruits. Either he must be obliged to his neighbours and thus betray his ignorance, or not wishing to remain in ignorance, and yet willing that his neighbours should consider him well posted in fruit lore, he sends a basket of sorts to the Editors of the "Journal."

One advantage of suspending the tallies is, that both head and under gardeners soon almost unconsciously acquire a knowledge of the sorts grown about the place. When nailing and pruning in winter and spring, they cannot but notice the differences among the sorts in habit of growth, sturdiness, weakness, short-jointedness, or otherwise of branch, &c.; also in summer, when weeding and raking the ground beside the trees, and pinching the shoots, they will have excellent opportunities for comparing the leaves and young shoots, and above all, the fruit will be an absorbing source of interest as it gradually approaches maturity. Now for a case in point. I called on a gardener of my acquaintance about three weeks ago to see a number of pyramidal Apple trees on the Paradise stock—a method of growing trees in which so many people are now becoming interested. Before seeing the trees he took me into his fruit room to show me their produce, which had been gathered a few days previously. Two sorts in particular struck my fancy, and, on asking the names, judge of my surprise when he

confessed he did not know them. This was the more reprehensible, as the trees were planted about three years ago, if not by his own hands, at least under his immediate superintendence. Had the names been suspended permanently from the trees, would I have gone without the desired information? I believe not. I am unable consequently to add trees of the same kind to my collection.

Now I come to the second part of the indictment, involving a certain class of nurserymen. The practice some of them adopt to obtain grafts of fruit trees is far from conducive to correct naming. The foreman, or even one of the under hands, as he can often be better spared, is dispatched to some gardening friend for a quantity of grafts. Whatever name is given is of course affixed to the young trees without much inquiry as to its correctness, nor is it difficult to understand that, in many instances, the name is only supposed to be correct, though in reality not so. Such trees when sold contribute to extend the evil complained of. Very few such nurserymen plant out a tree of each sort specially for fruiting, with an eye to prove the correctness of the nomenclature; and such sorts as do set fruit in the nursery quarters have the fruit taken off at an early stage, because, as say the nurserymen, "we require to grow wood, not fruit."

I was supplied early last spring with about twenty young Apple trees on the Paradise stock by a local nurseryman. Four of them fruited, of these one has proved to be wrong. If the same proportion of the others turn out incorrectly named, I will probably be under the necessity of troubling the Editors of the "Journal" to name some day a batch of five Apples. The above does not apply to the greater nurserymen, who, as a class, I am proud to say, would rather burn their trees than dispose of a single one which they are not certain to be correct to name.—A. R.

DALKEITH PALACE GARDENS.

Edinburgh, like London, has its suburban residences, not modern ones only, but also those of more ancient date, originally built for and occupied by the nobles, whose duty or interest called them to the metropolis; and the situations of many such residences are so judiciously chosen as to prove that good taste was by no means disregarded, but other considerations often determined the site. The turbulence of the times rendered it necessary to make every home of any pretensions a sort of fortress; and then inaccessible rocks, or sites by the coast or by the side of some stream that could be turned to good account to keep out an enemy, too often tempted the builder to disregard the position we now call beautiful, or what those of the last century would call useful; nevertheless, in some instances good sense did exercise its rights, and spots lovely in themselves, and commanding views of others equally so, were chosen as the sites of mansions or castles. In these cases the occupier at the present peaceful time has the advantage of inhabiting an historical place without the inconveniences such a residence often entails.

Dalkeith Palace, the noble seat of the Duke of Buccleuch, occupies a position near enough the northern metropolis to be of easy access before the days of McAdam, not to speak of his still more rapid-travelling successor George Stephenson, and is one of those massive piles of masonry which strike the beholder with respect more by their magnitude than by any especial merit in the style of architecture, although in this instance the latter is not without its claims to notice. Perhaps, however, the most remarkable feature is the fine site which the mansion occupies—sufficiently high to command a good view of the country without being so high as to be bleak. Higher ground is to be found in the rear, and the luxuriant trees around it give sufficient shelter; whilst perhaps the finest of the adjuncts is the river Esk, which flows past it, and is almost within a stone's throw of one of its fronts. The river, which I believe higher up is applied to some of the purposes of industry for which the town of Dalkeith is noted, flows through a park of great beauty and variety; and near the mansion its banks, especially those on the opposite side of the Palace, are sufficiently steep and picturesque, but they are richly clothed with foliage; and the general character of the district is smiling, and exhibits none of those rugged outlines which, however beautiful in a bright summer's day, convey but dreary notions of comfort in midwinter. The Esk at this particular place passes through a fine undulating country, and in its course through the park adds materially to the general effect. A bridge over the river at a short distance from the Palace looks

remarkably well, and gives access to the grounds on the opposite side, on which the gardens, the subject of the present paper, are placed. A carriage road from the highway and town of Dalkeith leads in another direction, while surrounding the noble pile grounds are judiciously laid out in that style of natural esse becoming a place where so much of rural comfort is united. No cutting up the lawn into petty insignificant flower beds, where the occupants could be easily guessed at as so many dozen, but large open spaces, intersected by corresponding masses of shrubs and trees, the whole being remarkably well kept. One side of the grounds slopes down to the river by a natural and agreeable incline of 50 or 80 feet; while on the opposite side is the carriage entrance and a fine lawn, sufficiently extensive to exercise a battalion of infantry, yet it is machine-mowed. Some fine trees form the boundary of this open lawn, and join with others flanking the river. Turning one's eyes in another direction one sees still nobler trees clothing the opposite bank of the river; and as the garden is in that direction, I crossed by the bridge and passed along the walk which intersects the woody ravine, noticing here and there Oaks and Silver Firs towering above shrubs of various kinds, which have been planted to assist the undergrowth, while on the rocky eminences grow Ferns and other graceful plants. On ascending the hill, after a walk of some distance, one finds himself in the vicinity of the gardens, whence Mr. William Thomson has at various times sent forth such examples of skill; and from what I saw, there seems to be no reason to expect that such will cease.

Large, noble, and exceedingly well managed as the garden is, there is one thing wanting to give it that imposing appearance which it ought to have, and that is a suitable approach—an approach which would convey to the beholder an adequate idea of its vastness. I know it is impossible to have such an approach from the nature of the ground, and it is also a fault to be found in most gardens. There are few places where the kitchen garden and forcing department have a sufficient air of dignity and compactness, the cause of this too often being that the place has been added to from time to time, and an incongruous whole is the result. Perhaps one of the best examples of a contrary description is the garden at Belvoir Castle, Leicestershire. But it must not for one moment be supposed that I say the garden at Dalkeith presents a want of uniformity or design; on the contrary, it is in this respect one of the best I know, but being placed somewhat high, and there being no higher ground commanding it, the various ranges of houses and pits, and the brilliant flower borders and other fine adjuncts, could not at one view give an idea of the grandeur which it actually possesses. I will, therefore, take it in detail, and whilst surprised at its treasures, perhaps one cannot regret being unable to see the outline of the whole at once.

I have said the character of the country about Dalkeith is somewhat hilly, and the kitchen garden and its appurtenances, including, by-the-by, a large space of dressed ground, occupy a plot of table-land or terrace, the garden part being level, or nearly so. The principal kitchen garden, a parallelogram, is situated about the centre of this plateau, while to the north there

Fig. 1.

1, *Lobelia speciosa*, with a single plant of *Centaurea candidissima* in the centre.

2, scarlet *Geranium*.

3, *Gazania splendens*, with an edging of *Cerastium* on the straight side next the main walk.

is a similar space nearly as large, almost entirely covered with glass structures. Another garden, with glass against the south wall, was southwards of the main kitchen garden, and to the south, again, a Rose arbour divided this plot from a lawn occupied by some thriving Conifers. Still farther to the south, and on what may be called the edge of the terrace sloping to the south, was an orchard of mixed fruits, while a large plot of kitchen garden extended along the west side of the whole, enriched with tastefully-arranged flower borders; and on the east, which may be called the approach side, a large extent of lawn extended over the edge of the hill facing the river, and communicated with circuitous walks leading to the Palace. The whole may be summed up as comprising three or four parallelograms of equal length adjoining each other, with their long sides to the south, their surroundings on the west and south sides being kitchen garden, reserve ground, and orchard; while on the east side is a large plot of dressed ground, with flower borders, &c., the lawn extending a considerable distance down the hill until it meets the wood fringing the river Esk. Taking, therefore, these compartments in rotation, I will begin with the northern one, which, as stated above, is mostly covered with glass.

In a garden so renowned for its forcing it may be supposed

that an extensive area of glass is devoted to each particular purpose, and that nothing in the way of crowding would occur; but I have no doubt that those who have the privilege of seeing these houses in winter or early in spring will see every inch of them as full as smaller houses usually are. Of course, in the fine hot weather of the early part of September only the permanent occupants of these houses were in their places, with the exception of things that were being prepared for other purposes, and these were numerous enough. But it is better to describe the outline of the houses first, and then their contents. Unfortunately I did not take such careful notes as I ought to have done, but I may remark that in general the houses were large, or rather long, and being arranged not unlike the streets of a town newly laid-out, their appearance from the high ground to the south-west was imposing, some lean-to vineries occupying the north wall, with a central house of another description undergoing alteration at the time I was there; while on the south side of these was a row of Pine pits, or rather houses, for there was a path inside of them. These pits had a short north light over the pathway, as will be described hereafter. Another row of pits of the ordinary description ran in front of them; then again another tier of lean-to houses, lower than the back ones, and another row of pits, the whole presenting a

mass of glass rarely to be met with. I may add that there was ample space for the Vine borders, paths, and other requirements, and that all was in good order, and well arranged.

As it is unnecessary to describe the contents of each house individually, an outline of some of the most important may be given. I will first take a late vinery, 110 feet long by 11 feet wide, with a high back wall, giving, consequently, a steep roof, which Mr. Thomson regards as the best for a late house, as insuring greater dryness than roofs of lower pitch. A large portion of it was planted with Lady Downe's Grape in most excellent condition, the berries large and well swelled out, and the bunches compact. West's St. Peter's was also good, though not so promising as Lady Downe's. A large white Grape, not much grown in England, also looked well. Its name is Calabrian Raisin, and it partakes somewhat of the character of the Syrian. There were several examples of it at the Edinburgh International Show, and its merits as a late-keeping Grape were much spoken of. I did not recollect seeing the Alicante, but undoubtedly it was there. Mr. Thomson had also some novelties in this house, of which I trust to hear something hereafter. Among them were some seedlings of great promise, one especially of that peculiar rich flavour so much sought after, and another promised to attain an unusual size. Other Grapes of well-known kinds were also grown, and all were good.

In another house of still larger dimensions than the last-named were very good Muscates, well ripened and finished off,

although the Vines had only been planted about twenty months, both the house and borders having been renewed. In this house most of the varieties of Muscates were to be seen, with other novelties, but the sort respecting which most likely inquiries will be made is Duchess of Buccleuch, which, as your readers are aware, is a white Grape. There has been some difference of opinion regarding it, but having seen it at Archerfield and Floors Castle, as well as at Dalkeith, I may safely say much that has been said against it is wrong. True it is not a showy Grape, and I hardly expect it will be a favourite on the exhibition-table, but for the dessert, I am told, it stands pre-eminent, being regarded superior to the Muscat, and in the opinion of some gardeners of high standing, who, like myself, tasted them both at the same time, the palm of merit on the score of flavour was due to the Duchess, which seemed to have more of that rich musky flavour which Chasselas Musqué when at its best possesses; at the same time it has all the firmness of flesh of the Muscat. The Vine, too, seemed to bear well. The bunches were medium-sized, and what I saw were compact, showing that few or no berries had been cut out after the usual thinning time. I cannot agree with those who find fault with it for cracking, for I did not see any berries disposed to do so. Some writers, I believe, have found fault with it on that account, and attributed the cracking to damp, but at Dalkeith a Vine of it in full bearing was pointed out to me growing over an open tank of water, and in as good condition as any other. It will, however, I trust be accurately

Fig. 2.

- 2, Lobelia speciosa.

- 3, Cerastium.
- 4, Single row of Geranium Brilliant next the grass edge.

tested another year in many places, and I have no doubt that it will have a host of admirers at a private table.

The central house of this line was undergoing some alterations at the time of my visit, and I believe it was intended for plants, and to present an ornamental front as becomes the central structure of a mass of crystal. There were, I believe, some other vineries against the back wall, as well as the two above described, but my notes are imperfect on this point; suffice it to say that the central house was intended to be a noble one, and the pits and other houses in front of it were cut through, so as to allow a wide pathway to approach this house, dividing the four rows of pits and houses in front of it into eight shorter ones. The next line to the back one was a span-roofed Pine pit or house on one side, and on the other a similar pit that might be used as a Pine pit at any time, but was employed as a plant house, and a great quantity of Geraniums were being prepared for winter flowering. This span-roofed house was 180 feet long by 13 feet wide.

Corresponding with the last-named range were the Pine pits or houses, 200 feet long by 13 feet wide, divided into three compartments. There was a short north light covering the pathway, with two pipes at the back, two in the front of the pit, and two underneath it. Tan was also used as a heating material. Some most excellent Pines were grown here. Several Smooth-leaved Cayennes were pointed out to me that were

expected to weigh 8 lbs. each, and some of 9 lbs. and upwards had been cut. This variety seems to be remarkably well grown at Dalkeith, as well as at Archerfield, and appears to be the favourite in Scotland, just as the Jamaica is at Manchester, and the Queen around London. Certainly I never saw such fine fruit of this variety in the south, and my impression was, that the Scotch Smooth Cayenne is a superior variety or is better managed. There were Queens also; a very good one upwards of 5 lbs. in weight had been cut just prior to my visit, and there were others in all stages of growth. Mr. Thomson likes them best in pots, but has tried the planting-out principle as well. These houses were all filled with fruiting Pines; succession ones were grown in some lean-to pits in front of those just described, and were all that could be desired.

In front of the fruiting Pine house, but separated from it by a broad path, there is a low lean-to pit, which although used as a cold pit at the time of my visit (September) is, nevertheless, furnished with hot-water piping for use in winter; and one compartment of about 100 feet long by 6 feet wide was filled with bedding Geranium cuttings, not in pots or boxes, but platted in the ground, and I understood they wintered very well there, heat being used when required, and in March they were taken up with balls and potted-off singly. The number of cuttings such a pit will hold gives some idea of the requirements of the place. At the time of my visit they

were fully exposed night and day, and I expect would be so until cold nights set in. The pit was a low one, and I believe a portion of it was used for wintering Strawberry plants for forcing, but a portion of it, 50 feet or more long by 6 feet wide, was filled with a fine collection of Alpine plants in pots, which I daresay were intended for some other place, but even where they were they were very interesting, all being carefully named, and many novelties amongst them. I was glad to see Mr. Thomson patronising this class of plants, which to my idea are quite as interesting as many fashionable stove plants; but, no doubt, they will have their day when the rage for colouring fades away.

In front of the pit last described is a set of Peach houses. One of these, 200 feet long by 8 feet wide, was more lofty than usual, there being a low front light as well as a short top one slightly leaning to the south as well as the main rafter, which was more upright than in the generality of houses. There were trees both against the back wall and also under the glass in front. I was told excellent crops had been gathered, and the appearance of the trees promised well for another year. There was an Apricot house adjoining, with trees trained against the back wall and others in front in pots, so as to give as much light as possible to the back, where the bulk of the crop was expected. The pits in front were devoted to Melons, Cucumbers, and the like, the whole being heated by hot water; and such crops as Capsicums were luxuriating in some of the compartments, but I had not the opportunity to notice all.

My limits forbid anything but a hasty glance at the kitchen garden proper, which is at Dalkeith made more ornamental than at most places of a like kind, but the crops of vegetables seemed to be good and abundant, and the Peach trees on the walls well covered with fruit. Broad walks divided the kitchen garden into compartments, and wide borders of the most popular hedding plants margined these walks. These borders, and others outside of the garden proper facing the east wall that bounds all the compartments named, form the principal flower garden at Dalkeith; and when we are told that 60,000 bedding plants are turned out every season, it will easily be conceived that these are very large. A border in front of one of the hothouses—not a vinery or Peach house, for such borders are held sacred, but an ordinary forcing house—had a suitable path in front of it, and then a neatly trimmed Box hedge, in front of which was a row of a scarlet Geranium of tall growth; next a row of Geranium Alma, silver-edged; then a broad band about 4 feet wide of Lobelia, with single plants of Centaurea candidissima at about 10 feet apart in the centre; and in front of this band of Lobelia was a Cerastium edging adjoining the permanent Box edging of a principal walk. This border, 400 feet long, looked remarkably well. Another border of the same length on the other side was somewhat differently planted, a band of Gazania being substituted for the Lobelia, with dots of Centaurea 10 feet apart. This border was 12 feet wide, and one of its lines consisted of Calceolaria Aurantia, which was said to be the best used at Dalkeith.

Some of these borders were divided by Box edgings and narrow gravelled walks into pleasing running patterns, of two of which I give designs. One of these is in front of a Peach house, but an ample space from it is allowed for the roots of the trees to have full scope. The portion required for the ornamental border was 14 feet wide and upwards of 400 feet long, and it was edged with Box, and planted as in *fig. 1*.

On the opposite side to this running pattern was a ribbon pattern, planted somewhat in the same style as others previously given—viz., the edging next the main walk (inside the Box) Cerastium, then a band 4 feet wide of Purple King with patches of yellow Calceolaria at every 10 feet, then a white-variegated Geranium in double row, and finally a tall scarlet Geranium at the back. This looked very well.

Another border of a running pattern in Box (*fig. 2*), formed an edging to the broad walk that ran along the side of the high wall separating the kitchen garden and forcing department from the lawn or dressed ground that descended to the river, or rather to the wood that fringed the river. This border—450 feet long—was in what I have been accustomed to call the Florentine chain, but I am not sure if that be the proper term; *fig. 2* will, however, explain it.

The above adjoin a large piece of closely-shaven turf but little broken by shrubs, and sloping to the eastward. On the other side of the walk is the wall alluded to, covered with climbing Roses and other ornamental plants, with a ribbon border in front of it planted thus, beginning at the walk:—1, Verbena Miss Hamilton, scarlet; 2, Band of Alyssum varie-

gatum 3 feet wide, dotted with a scarlet Geranium at every 10 feet; 3, Verbena Purple King; 4, Calceolaria, yellow; 5, Geranium, scarlet, tall variety.

Amongst other features of this fine place was an arched Rose arcade, bordering the space set apart for a pinetum. This arcade, like most of the borders described, was 450 feet long. An arched wire frame of suitable height and width was well covered with climbing Roses, and at the proper season no doubt looked well. Beyond that, Wellingtonias, Ratinosporas, Thujas, and other Pinuses were well represented. Other borders were worthy of notice, but sufficient is given to show the extensive scale on which this work is carried on at Dalkeith, the whole being so well done that the most fastidious would have a difficulty in suggesting an improvement; while the urbanity and kindness on the part of Mr. Thomson in showing the writer and his friend everything connected with this fine place, at a time, too, when so many other pressing matters might have called him away, ought not to be passed over without a due acknowledgement. Dalkeith and its gardens will always be thought of as one of the sights which come far and few between, but the fame of the place is already sufficiently known to require no further comment, as its reputation may be said to be European, if not more than that.—A CORRESPONDENT.

[This communication ought to have appeared long ago, and possibly some alterations may have taken place in this important garden, but we believe the main features are the same.—Eds.]

THE VEITCH MEMORIAL.

A GENERAL meeting of the subscribers to Mr. Veitch's memorial was held at South Kensington on the 21st inst., James Bateman, Esq., F.R.S., in the chair.

From the report, which was read by Mr. Moors, it appeared that the total sum raised is £1012 12s. 9d., from which, after deducting the necessary expenses, there remains the respectable amount of £890 18s. 4d., which will be invested in the names of trustees, and the annual interest arising therefrom will be devoted to the awarding of prizes for the advancement of horticulture in the three kingdoms.

An admirable full-length portrait of Mr. Veitch was presented to the trustees by Robert Crawshaw, Esq., of Cyfartha Castle, and is at present suspended in the Council-room of the Royal Horticultural Society.

It was moved by Mr. John Fraser, seconded by Mr. D. Wooster, and agreed to *nemine dissentiente*—"That the report of the Central Committee be adopted, and that the said Committee be hereby empowered to carry out the recommendations of the said report."

It was further proposed by Dr. Hogg, and seconded by Mr. J. Gibson, and also adopted unanimously—"That the thanks of this meeting be conveyed to Robert Crawshaw, Esq., for his gift of a portrait of the late Mr. James Veitch, in furtherance of the Veitch memorial."

On the motion of G. F. Wilson, Esq., seconded by Mr. Lamb, it was agreed that a cordial vote of thanks be given to the Chairman for his kindness in presiding on the occasion.

The trustees appointed are Mr. G. F. Wilson and Mr. Thomas Moore, the Treasurer and Secretary to the fund, Mr. Harry J. Veitch, Dr. Robert Hogg, and Mr. Zadok Stevens, representing England; Mr. William Thomson, representing Scotland; and Dr. David Moore, representing Ireland.

WORK FOR THE WEEK.

KITCHEN GARDEN.

It is time to think of forcing a little *Asparagus* for early use. The principles applied to the forcing of Sea-kale are in the main applicable to this delicious vegetable, except that *Asparagus* requires an abundance of air when growing through the soil. Prepare a plot of ground, by thorough digging and manuring, for a few *Mazagan Beans*. Let the *Beet* and *Carrots* be taken up and stored away directly. It is a good plan to completely cut off the heads of the *Carrots* below the neck, thus checking their tendency to grow. A few *Parsnips* for present use may be taken up; they wilt, however, keep well in the ground, and thus circumstanced they may have a coat of manure spread over them for the next crop, and be tramped out as wanted. For the earliest *Peas* prepare a piece of ground as recommended for Beans.

FRUIT GARDEN.

Planting, pruning, training, trenching, &c., are matters that

belong peculiarly to this dormant period, and having before disposed of planting and trenching by directing attention to their importance, I will now offer a few remarks on pruning. The habits of fruit trees vary, more especially as to the manner of forming and exhibiting their buds. There is no difficulty in distinguishing the fruit-bearing portions of the Apple, or of bush fruits in general, whilst the Apricot and the Filbert are at this period somewhat obscure in regard to this point. Even in the Pear, more especially some of the kinds, such as the Passe Colmar, the Seckle, the Marie Louise, and some others, it is difficult to prune with safety in the early part of winter. For these reasons prune bush fruit the moment you can find time. Follow closely with Cherries, Plums, and Apples, and towards Christmas lay aside the knife until early in February, when the Filberts will be blooming; then after a slight thinning of the crowded and inside spray, male catkins may be brought, if requisite, and suspended amongst the bushes. The Apricots will, by this time, give unequivocal signs by which to know the true blossom-buds, and may immediately receive their pruning. The Peach and Nectarine will succeed the Apricot, and may be followed by the Pear, and lastly by the Fig. In pruning bush fruit, thin liberally. Let no two branches of the Black Currant and the Gooseberry touch when finally thinned; these seldom require shortening; an equal and judicious thinning is, therefore, everything here. In pruning Apples, the thinning of the branches or old wood should be the first step; this, however, requires caution. Mr. Knight, of Downton, was much opposed to cutting out large limbs, unless an urgent necessity existed. His authority is too weighty to be passed over easily, more especially as he lived most of his time in a cider district. In thinning the young wood of espalier trees, remember that the first point is to secure a continuance of leading shoots to form a compact tree, and the second, to secure a free admission of light to all parts of the tree. The same remarks will apply to the pruning of all the rough espaliers or dwarf standards of any kind in the kitchen garden. Raspberries may now be planted and pruned.

FLOWER GARDEN.

Plant all autumn bulbs without delay. Let all biennials be planted out soon. Such plants as the Sweet William, Wall-flower, Canterbury Bell, &c., are of great use in flower borders, and may be planted three or four in a mass. Dahlias should be marked forthwith. Pinks may be planted out, and Carnation layers or pipings may still be potted to place in frames. Ornamental climbers on trellises, &c., in blossom should have a protection on nights of a frosty character. Much valuable late blossom may sometimes be insured by such simple means, as it not unfrequently happens that after one or two severe nights the weather becomes mild for weeks.

GREENHOUSE AND CONSERVATORY.

The period has now arrived in which the increasing scarcity of flowers in the decaying parterre should be compensated for by those conservatory flowers peculiar to winter, and by retarded summer flowers. These together, under good management, will lead us imperceptibly up to the products of the forcing pit, which form a distinct section, and, of course, require a separate course of treatment. The Camellias will form most prominent objects in the conservatory for the next six months, and those which have been managed for forcing, as it is commonly called, according to previous directions, will be in full gait from this period till Christmas. Such plants should now have weak and clear liquid manure, and a temperature of from 50° to 55°, descending at night to 45° in dark weather. A very considerable amount of atmospheric moisture should be afforded them; drip, however, must by all means be avoided, and the syringe is not to be used. The Chrysanthemums may be treated with manure water constantly, and all suckers and waste shoots trimmed away. Early Cinerarias should now be coming into blossom, and, above all, the tribes for winter flowering; these require all the light which the season affords. They should be kept close to the front glass until in blossom, be frequently syringed in a light way, and if the shelf is warmed by means of a flue or pipe beneath, so much the better. The Chinese Primrose will do in a more shady situation; spring plants sown last March will bloom freely now under ordinary circumstances; they do not endure dry heat. The Hybrid Roses, as before observed, will enjoy a similar treatment to the Chrysanthemums, whilst the Tea Roses will class better with plants of intermediate character, requiring a little more warmth with a permanency of atmospheric moisture. Such are the Euphorbia jacquiniiflora, Gesnera zebrina, Achimenes picta, Gesnera ob-

longata, Linum trigynnum, Plumbago rosea, Begonias, &c., all of which should have a temperature of 60° by day, rising to 80° by sunshine, and sinking to 50° at night. The above are all most useful and interesting flowers for the dead of winter; so are some of Mr. Fortune's Chinese plants, such as Abelia rupestris, Azalea squamata, Jasminum nudiflorum, and Weigela rosea; the last, a most admirable forcing shrub, can be brought into flower when very small for drawing-room purposes. Where everything is grown in one house it is of the utmost importance that there should be a proper relation between the amount of heat and light. In such a house the proprietor naturally desires to have flowers late as well as early, as far as such can be carried out. To effect this fires must be in use occasionally, even at this period, and those who are thus circumstanced, I would advise to beware of night heat; 55° will be sufficient in such a structure for the present. Let the thermometer rise to 70° or more during sun-shine, observing if such is fitful to drop it to 60° in the day, if dull weather takes place.

PITS AND FRAMES.

See that the Mignonette has a very light situation, and is plunged close to the glass at the back of the frame free from drip. Store Verbenas growing rapidly should have their tops pinched, also Petunias, and other ordinary mass flowers. Give all the air possible.—W. KEANE.

DOINGS OF THE LAST WEEK.

The heavy rains have made us independent of the water-cart for a time, and we are reaping the benefits of increased spouting. The rain has interfered with cleaning and repairing sashes for the winter, but many of the sashes being dry in sheds, work could be done there when it could not be carried on out of doors. For brick pits sound wall-plates are of great importance, as we have often found to our cost that rats which could enter in no other way soon made a hole through the wall-plate when it was decaying. Many a score of young plants have we had eaten-over in winter from this cause alone. Last year, from this cause, our young Calceolarias suffered from rats and mice, and singularly enough, though Aurea floribunda was pricked out as cuttings in several places a good way apart, they were singled out to be nipped close to the ground. We have strong wall-plates put on, ready for shortly commencing with Calceolaria cuttings, as the later they are put in the better, generally, do they thrive with us, if we can get them in before frost to any extent attacks them. With us little as yet has suffered except the Colera, though everything looks washed in the flower beds now, and even the Calceolarias, which have stood well all the season, have now few fresh flowers left.

Our routine has been so much the same as in previous weeks, that we will say a few words on some matters that have taken up a considerable portion of our time.

Insect Enemies.—Much may be done now in the way of prevention, as has been elsewhere alluded to, and what is done now will save labour and expense in the following spring and summer. We have much need to depend on cleanliness and modes of prevention, as there are many subjects that we could not syringe overhead with our water in summer, or at any time when fruit was approaching maturity. We have rarely been able to syringe Vines after they were in full leaf. Cucumbers and the like we syringe, because the older leaves are gradually removed as younger growth takes their place. Even our soft water in tanks is apt to leave a sediment on leaves syringed. With preventive measures we have generally escaped without being much troubled with insects, so that we have not been able to try to a great extent the many remedies that were to kill all such vermin as if by a miracle, and not hurt the most tender plant. We believe that Gishurst, the various powders, insecticides, Messrs. Veitch's mixture for bugs, &c., and the different combinations of tobacco paper and tissue, are all good, and so far effectual, if the vendors would not speak so enthusiastically about them, and if people were not thus led to believe that each and all were to effect such wonders as to stand in the place of timely application and unremitting attention. As often stated, when plants are covered with insects, remedies are of little use, as what would kill the insects full-grown, will not kill the young ones, and what would kill all that are alive will not touch those not hatched but ready to be so. Failure often arise, too, from not attending to the directions given. Too strong a dose will be too much for plants as well as insects. It is better to repeat the dose than to have it over-strong.

For *red spider* we have found nothing more disliked than a moist atmosphere with the smell of sulphur fumes in it. For *green fly*, where washing overhead cannot be given, we have found nothing better than tobacco-smoking, and the best tobacco is the best material, if motives of economy do not render it advisable to use tobacco paper instead. We find Griffiths's tobacco paper very safe, and we considered it best until we used that sent out by Mr. Appleby along with his fumigator, which may be described as a three-footed kettle with holes in the bottom and holes in its lid. We have never found such effects on green fly produced by such a small quantity of material. The direction must be attended to—not to stop in the place after the tobacco is fairly lighted, and it burns so slowly and surely that there is no necessity for doing so. For general purposes, for keeping insects away and disposing of them when they come, and when we can use liquid, our mainstay is weak soft-soap water.

Of all intruders we think the *mealy bug* about the worst to get rid of, for it lodges in so many nooks and crannies. Until lately we have had no trouble with this pest for a great many years. We believe it came to us about the time the new varieties of *Coleus* were first brought out, and we fear we shall have some trouble with it before we free ourselves of it. We have some Figs that were first turned out of pots into a low pit as bush plants, and that have borne very well for many years. Partly from carelessness, these plants had little done to them in the way of cleaning for two or three years, as they did not seem to require it. This summer the stems are infested with scale, and what is inconceivably worse, through some fine *Coleuses* standing at one end, they are also attacked with the bug. The withering leaves were taken off and burned; the plants have been syringed several times with soft-soap water at about 170°, as we were afraid to use it warmer in case we should hurt the young Figs showing like small pinheads. The stems and shoots were washed with cloths and a brush. Every moveable board was removed and washed, and all the walls, woodwork, &c., thoroughly syringed with the hot soap water, and then well scrubbed down before being fresh limewashed. The surface soil of the bed after all this washing was carefully scraped off to the depth at least of 2 inches. If we could spare the house as long we would wait for frost to nip the trees a little before we painted them over with some suitable mixture. The main shoots and stems had been painted with lime and Gishurst three years ago, and wherever that remained there was no scale. After the washing, when we syringed again with the hot water, we could see it brought out some small bugs from their holes and crannies. We hope we shall thus get rid of the enemy, using a sharp look-out, as of all insects it is the most obnoxious to us, though we have had little to do with it since our young days.

Of this we are sure, that however and with whatever mixture, dangerous or otherwise, plants may be cleaned, if the cleaning is confined to them this insect will never be eradicated from a house where it has once gained an entrance. It will find a home in every hole and cranny of sashes, stages, shelves, and walls, and unless dislodged or shut up, there it will remain until it makes a feeding ground of the plants. The thorough cleaning of houses as well as plants is all the more important, as this insect is so easily carried from house to house. We believe that very often, quite inadvertently, workmen take the insect on their clothes from house to house. Notwithstanding all this care, for which the wet days gave a good opportunity, we shall keep an extra look-out on these Fig trees next season. For the scale, we feel confident that will be destroyed. We do not feel quite so certain about the mealy bug, as a few might escape the washing and the smearing of the shoots. But for the scale appearing, we had made up our mind to dispense with the unnatural system of smearing the stems, and be satisfied in the case of deciduous plants with giving a good washing. The smearing can only be useful as a means of shutting up all small insects, and keeping smaller eggs from the air, so that if hatched the young have no chance to breathe. For this purpose, as the simplest means, perhaps nothing is more effectual than clay paint with or without a little soft soap in it.

Numerous remedies have been proposed for *American blight* on Apple trees, an insect which in its woolly clothing much resembles the mealy bug. Among them are washes, turpentine, oil, tar, &c., more or less prejudicial to the trees, as well as to the insects, but we have never seen anything more effectual than a good washing with warm water when the leaves fall, followed by covering all over with clay paint, or a mixture of clay and lime, and even limewashing itself. Towards spring,

if there was a crack or two, or the insects appeared at any crack or hole, there was needed but a fresh daubing. Once we had some standards 20 feet in height very much infested with the insect. These, after the fall of the leaf, were syringed with the nozzle end of the syringe, using rather thick limewash, and had the dose repeated at midwinter, and once again as the buds were swelling in spring, and no more American blight appeared. With low pyramids or bush standards the brush might have been used, but even in their case the wash applied with the syringe, so as to trickle into every cranny, is generally effective. Some time ago we had the American blight on some bush Apple trees, but after using limewash with some soot and clay in it in spring, to deter the birds from picking the fruit buds, the insect disappeared. At other times, when the insect appeared just here and there, we have known it destroyed by daubing up the places with thickish clay paint, and if this cracked, so as to let some air in, the operation was repeated. On the whole, then, for enclosing eggs and small insects, we question if there is anything much better and simpler than clay; anything nasty, but harmless to vegetation, might make it a little more effectual.

In the case of *scale* on growing plants, we consider all mixtures in which turpentine or strong acids form a part to be dangerous to plants as well as insects. Strongish soap water, glue water, &c., are useful, to be followed with hard syringings with heated water, say 120°, in twenty-four hours or so; but when the foliage was very fine, as in the case of some *Acacias* that are rather subject to the scale, we have found dipping the plants overhead in a thin clay paint as good as anything we ever tried, syringing when the plants were too large to be dipped. The efficacy depended on every part of the plant being covered, and then laying it carefully down in a dry shady place. In from twenty-four to thirty hours the smearing would be dry enough to shake off or rub off between the hands, and in general the scale would go with it, and some good syringings would make the leaves all clean. By such means the bug and scale may be got rid of if confined to the tops of plants, but it will be more difficult to clean them when the insects go down to the roots. In such a case, as they will be sure to rise at their leisure, the whole of the earth would require to be washed away, and the roots well washed before the plants were repotted. As a sort of test or trap, if you wish to know if a thrips is in a house, put a few *Kidney Bean* plants in it—the thrips will be sure to find out the plants; and again, a healthy *Coleus* plant in a stove or warm greenhouse will soon tell you if you have a mealy bug at hand, for of that plant they are very fond.

Planting and Transplanting.—These matters will most likely occupy a considerable portion of our time. The last two seasons have been unfavourable for all planting on a large scale, whether for ornament, for profit, for cover, or for all combined. The ground was so dry twelve months ago that planting in the autumn was in many places quite impossible, and spring planting was followed by the driest summer, on the whole, we ever experienced. Now, the rains, though they have not gone down much, will render planting more practicable. Taking circumstances as they are, a few hints may be useful, and the old rule still holds good for all exposed places, "plant thickly and thin quickly." The first part of the rule is based on the fact that purchased plants generally stand thickly in the nursery, and setting them out thinly exposes them to a greater danger of having their vital juices sucked out of them by the keen frosty winds of spring. Whilst they stood close together in the nursery rows, the one protected the other. On this account where much planting is to be done in exposed places, the time and labour would be anything but lost, if the young trees were set out thinly in nursery rows for a year or two on the estate before being moved to the plantation. The thinning quickly is just as important where a healthy plantation is desirable, and the thinning should commence as soon as the branches of the young trees approach each other. If the thinnings at first are not large enough to be useful, the trees might be pruned-up considerably for a year or two before cutting out, so that the others might have room. For anything in the way of cover the permanent trees should feather to the ground. When trees are left thickly, all the lower branches must die from want of air. Frequently a whole plantation becomes unhealthy and covered with insects from mere exhaustion from want of thinning. The soil that would have supported one hundred trees in luxuriance, will hardly keep three or four hundred alive. The same rule holds true as to ornamental plants. To make them grow quickly they must be nursed, but the nurses must be removed as the principal plants need the room. To

have the plants on the estate is in all cases a great advantage—the roots may be muddled as taken up, and not too many taken up at a time. Many forest trees and ornamental shrubs are greatly injured when brought from great distances, for they are so dried and heated in the journey. For raising trees and shrubs, on the mere principle of the division of labour, the nurseryman will ever beat the gentleman and his gardener, or even forester; but a great gain would often be obtained by having the plants on the place a year or two before final transplanting. The extra time, room, and labour will be anything but lost—quite the reverse.

One more hint for the present. Much would be gained if it were well understood that cheap plants and cheap planting are anything but synonymous with profitable planting. Owing to the rage for mere cheapness and the severe competition, nurserymen strive to meet it, and advertise plants of certain heights at very low prices. They can only sell at these prices by having the plants standing thickly, almost touching each other's stems in the row, and thus occupying but little ground. Such protected plants turned out on an exposed hillside, say 4 or 5 feet apart, can hardly stand the severe exposure; the bark, &c., being so tender and fine. Hence the reason, as above stated, for wider planting and home nursing for a year or two. The nurseryman cannot give you the advantage of transplanting and re-transplanting without a corresponding charge, but that extra charge would in most cases be anything but an extra expense. We are sure that the present system of drawing plants up thickly and selling cheaply will be, as a rule, to the advantage ultimately of neither seller nor buyer. In advertisements we should like to see a fresh feature—not merely the height and price of the plants, but the times transplanted and the distance they stand from each other. The distance must be paid for, but those who buy and plant at once would find out that in the end it was cheapest to buy proper plants. A few years ago we planted some beautiful Larch 30 inches in height, with robust stems feathered to the ground, nice little pyramids, and we believe not one failed. They stood in rows 3 feet apart and 2 feet from each other in the rows. We paid a little more for them than for trees of a similar height that stood thickly in the nursery rows; but for security against failures, thinner planting at first, and rapid growth afterwards, they were well worth three times the money given for the others. There would be fewer yearly makings-up of plantations and shrubberies if, either at home or at the nursery, there were more preparation and room given to the plants before final transplanting. Let those interested look to it; they will then see it is no loss to pay the grower for transplanting and additional room.—R. F.

TRADE CATALOGUE RECEIVED.

Ellwanger & Barry, Mount Hope Nurseries, Rochester, New York. *Descriptive Catalogue of Fruits. Descriptive Catalogue of Ornamental Trees, Shrubs, Roses, &c.*

TO CORRESPONDENTS.

* * * We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By doing so they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Too MANY QUERIES (*An Old Subscriber*).—There is no book containing pictures of every known plant. Heat your small greenhouse by a gas stove. We name Ferns from specimens. You could safely sow the seeds as you mention. Other queries in "Our Letter Box."

PEBBLES ON SHELVES at Kew (*A Constant Reader*).—The pots rest on fragments of Derbyshire spar spread on the shelves.

PEACH TREES (*J. A. Dublin*).—Peach trees without glands are more subject to mildew than those with them. Have Rivers's Early York and Dr. Hogg in your greenhouse.

LATE PEARS FOR SOUTH-EAST WALL (*G. G.*).—Bergamotte Espereu, Beurre de Rance, Colmar, Glou Morcean, and Ne Plus Meuris.

PEARS FOR WEST WALL (*B. S.*).—To ripen from October to January inclusive, we advise for quality and productiveness, Marie Louise,

Beurré Diel, Hacon's Incomparable, and Glou Morcean. Gansel's Bergamotte and Brown Beurré are also excellent. You do not say where you live, therefore we can form no idea as to whether Stimpson's Apricot would succeed or not on a west wall, but unless you are south of London it would not. A Green Gage Plum would do very well, and so would Kirke's, Victoria, Jefferson, and Coe's Golden Drop Plums.

FRUIT TREES FOR EAST AND WEST WALLS (*A Cottage Gardener*).—On your 57 yards of wall with an east and west aspect, you will have room for six trees on each side. The west devote to Pears—viz., Flemish Beauty, Marie Louise, Beurre Diel, Passe Colmar, Van Mons Léon le Clerc, Glou Morcean; and between these we should have vertical double cordons, and also at the ends, or seven trees—viz., Beurré d'Amanlis, Louise Bonne of Jersey, Beurré Giffard, Beurre Superfin, Josephine de Malines, Ne Plus Meuris, and Bergamotte Espereu. The east wall will suit Plums and Cherries. We should have at least one Cherry; Empress Eugénie, an early form of May Duke, being excellent. Plums: Green Gage, Jefferson, Kirke's, Victoria, and Coe's Golden Drop. Between these you can have double vertical cordon Apples—viz., Kerry Pippin, Callini, Adams' Pearmain, Cockle Pippin, Golden Pippin, Sykehouse Russet, and Cox's Orange Pippin. For the north wall nothing does so well as the Morello Cherry. One would be enough. There is no chance of a Black Hamburgh or Royal Muscadine Vine succeeding on either an east or west wall.

KEEPING WALNUTS (*G.*).—You will see what we said last week. If stored in the green shell this decays and imparts a bad flavour to the kernel.

WHITE GRAPES (*Southamptonensis*).—We cannot name a Grape from one or two berries. It may be Syrian, White Tokay, White Lisbon, or even White Muscat. From a portion of a bunch with leaves we might be certain of the name.

VINERY AND CONSERVATORY (*R. I.*).—We think you are distressing yourself unnecessarily about the heating of your houses. We have no doubt the boiler you have will heat the three houses. Of course there is a greater risk in heating three houses than in heating one by a boiler, as in the one house, if the boiler gave way, one house only would be in danger. To make yourself thoroughly secure it would be best to have two boilers, both connected with the main flow and return, and both shut off by valves if desirable. If anything happened with one boiler you could disconnect it and work the other. The boiler you have, however, may do its work well for many years without a flaw. As far as we know, the mode of heating is good. The boiler is placed, say, near the west end of the vinery, and pipes go across the back or north end of the conservatory until they reach the next vinery. The pipes from the boiler across the end of the conservatory act as flow and return, and from thence, we presume, by valves or otherwise, the other houses can be heated separately or all together. The four pipes round the vineries will be ample; but as we presume the conservatory is a span 20 feet wide, two pipes at each side, and at the south end, minus the doorway, would do to keep out frost; but to maintain a stove or tropical heat in winter, you would need nearly double the piping if the house is at all lofty. The arrangement of the conservatory must be a matter of taste. If rather low, have a border for plants and climbers all round, a walk all round, and a bed in the middle; if lofty enough, then borders, but a narrow stage all round, and a stage of flat sparred table, or a stone or slate platform, in the centre. The 32-oz. glass will be warmer in winter than thin glass. Roses in pots for house culture should be managed according as you force them much or not. The less they are forced—that is, brought on very gradually, the better will the blooms be. The pots should be well filled with roots before being set in the house. If out of doors now, protect the pots from frost.

DESERT AND PRESERVING GOOSEBERRIES (*J. C.*).—For desert—Early Green Hairy, Pitmaston Green Gage, Red Champagne, Yellow Champagne, Warrington, and Whitesmith. These have all small highly-flavoured berries. If you wish for larger, then of the large or Lancashire prize sorts—Red London, Dan's Mistake, and Conquering Hero. Yellow: Catherine, Leveiler, and Drill. Green: Thumper, Stockwell, and Telegraph. White: Antagonist, Freedom, and Hero of the Nile. For general purposes Crown Rob, Ironmonger, Keen's Seedling, Roaring Lion, and Warrington, with Runkhullion for bottling.

AMORPHOBALLUS HULBIFERUS TREATMENT (*Idem*).—It is hard, succeeding in a sheltered border well drained, and does well in sandy soil with a portion of sandy peat. The ground about the plant should be mulched with partially decayed leaves that may remain on until spring, and then be pointed-in. It is also known as *Arum hulbiferum*. The broad-leaved plant is *Escallonia rubra*, and the narrow-leaved *Daphne Cneorum*.

SALTING ASPARAGUS BEDS (*Idem*).—We do not recommend the salt to be applied at the time that the haulm is cut off and the beds manured for the winter; but in spring, when you dress the beds, give a dressing of salt, and another in May.

LATE PEAS (*Colonel G.*).—The best late Peas we have partaken of this autumn were from the garden of B. Drew, Esq., Streatham. They were British Queen, and the gardener, Mr. Baldwin, said that they were sown very deep on the 29th of May, were watered about a week after twice, but no mulching was put over the roots. They will continue bearing until the end of this month.

PRUNING PEACH TREES (*W.*).—You may cut out the old wood now, and during the next month you may perform whatever pruning is required; but as you practise summer-pruning, but little will be needed by the present year's wood and that for next year's fruiting.

GATHERING MEDLARS (*C. N. B.*).—Now is a good time to gather them. The proper time is when they come away freely from the tree, which is usually when the leaves have begun to fall. They should be gathered on a fine day.

RHUBARB GROWN FOR MARKET (*H. K.*).—We believe the market gardeners near London make fresh plantations annually—taking up the old roots for forcing. This is what Mr. Cuthill says in his little book on "Market Gardening." "Rhubarb-growing out of doors is so simple that little can be said respecting it. The ground being heavily manured, a plant is taken up and divided into as many eyes or buds as it possesses. These are planted 4 feet apart, and by the autumn they will have produced roots from 6 lbs. to 10 lbs. in weight. The oldest roots are generally taken up for forcing; and by always having a good rotation, the grower has the power of continually cleaning the ground, and thus obtaining a heavier crop. The forced plants will furnish eyes for a continual succes-

sion, without growing plants for the purpose, and the eyes may be divided and planted again for a main crop."

CAULIFLOWERS MAGGOTED (N. C. H.).—We cannot account for Cauliflowers sown in April not having headed before, but we think you have mistaken Cauliflower for Broccoli, which will not head before next spring. Both are subject to the ambury or club, which has been unusually prevalent this season. We know of no remedy; but it is said that charcoal dust spread on the ground about half an inch thick acts as a preventive, and a dressing of gas lime, twelve bushels to the acre, has been found to ward it off. It is also said that fresh soot, one gallon to a pound of sulphate, brought to the consistence of thick paint, will keep the maggots from plants, of which the roots and stems are dipped before planting. All you could do now would be to water the plants with ammoniacal liquor from the gasworks, diluted with six times its bulk of water.

POTATOES (H. S.).—Apply through some friend to the dealers in the Borough Market, or else advertise them, saying the price you require, &c.

SHRUBS FOR LOW SOUTH WALL (E. E.).—*Chimonanthus fragrans*, *Cydonia japonica*, *Indigofera floribunda*, and *Cotoneaster Simmoudsii*, it being only partly evergreen, the others being deciduous. Of evergreens, *Ceanothus aznreus*, *C. dentatus*, *Garrya elliptica*, and *Ligustrum japonicum*. For the north wall, *Calycanthus macrophyllus*, *Crataegus Pyracantha*, *Cotoneaster microphylla*, and *Ivy*.

TREATMENT OF A HOLLOW ASH (S. Adams).—There are many associations about old hollow trees that make people anxious to preserve them, though afraid the first tempest will bring them down. We have seen old hollow trees preserved and thriving afterwards by filling the hollow with flints, bricks, &c., and running the mass firm with thickish concrete. We have known some cases in which the trees seemed to take a new lease of existence, making fresh wood and adding layers of fresh bark every year. We are a little doubtful if it would be worth while doing this in your case, as you speak of encasing the outside with bark. If there is no bark there can be little or no life. We have known cases, however, in which hollow trees, treated as above, and with spaces all round where the bark seemed gone, have become covered with fresh bark on all such places being coated with cow dung and clay kept on with cloth to exclude air. This could only be done when the head of the tree was fresh.

SELECT FUCHSIAS (H. F. T.).—*Agnes*, *Avalanche*, *Empress*, *Heather Bell*, *Enchantress*, and *Innocence*; the preceding are light. Dark sorts—*Haven*, *Blue Boy*, *Duadem*, *Lord Elcho*, *Emoch Arden*, and *General Grant*.

SELECT ROSES (Idem).—*Hybrid Perpetuas*: *Alfred de Rougemont*, *Caroline de Sausal*, *Charles Lefebvre*, *Gloire de Saintenay*, *Jules Margottin*, *Leopold I*, *Madame Victor Verdier*, *Maréchal Vaillant*, *Pierre Netting*, *Prince Leon*, *Senator Vaisse*, and *William Griffiths*.

TROPEOLUM TUBEROSUM (Rash).—If it is planted out against a south wall the plant will need no protection in winter, except mulching over the roots and covering with partially-decayed leaves or dry short litter to the depth of 3 inches, removing the mulching in March. It would be advantageous to shelter the shoots with mats or canvas in spring, in case of severe frost after growth has commenced. The plant is only half hardy, and does not usually flower well out of doors except in warm soils and situations. *T. azureum* and *T. tricolorum* will, no doubt, start again. They will need to be kept in the greenhouse in a light position.

WINTERING GOLDEN FEATHER PYRETHRUM (Berkhampstead Subscriber).—It is not necessary to place the plants in a greenhouse, though it is often done. They winter quite safely in the open ground, being perfectly hardy in all well-drained soils. This Pyrethrum stands the winter best in light dry soil in a warm situation. It is not necessary to raise seedlings every year, for it is readily increased by slips or cuttings put in either in spring or autumn in a gentle hotbed, though they do well in a cold frame in August. Seedlings, however, are the most free-growing. The seed should be sown in July, and the plants pricked out when large enough in light soil in a sheltered position. They should be put out about 3 inches apart. In spring they may be planted where they are to remain.

SOWING GORSE OR FERZE SEED (Idem).—It is best propagated from seed, which should be sown in March. It prefers light dry silt. We admire the common Gorse as much as anyone, but think it out of place in a garden, being inferior to the double-flowering, which we have in large clumps, and no yellow-flowering shrub can surpass it when in full bloom. Plants in pots may be had at most nurseries at a cheap rate. We have it in groups by the hundred.

PROTECTING PASSION-FLOWER (An Old Subscriber).—It is necessary for us to have some data in order to form an opinion. You do not say what the kinds are, nor in what position they are grown, but we presume they are the hardiest sorts, which in the midland counties require a south wall, and a protection of mats or straw in severe weather, to be removed when it is mild.

THRIPS ON LAPAGERIA ROSEA (X. of Sidmouth).—The leaf sent us is infested with thrips. Your remedy is to shut up the house on a calm evening, and fill it with tobacco smoke so densely that a plant cannot be seen from the outside. You should repeat the fumigation next night but one, and two days afterwards give a thorough syringing. Your plant must have been seriously neglected as regards water, otherwise it would not have been in such a bad state, and the atmosphere has been much too dry.

GESNERA ZEBRINA FLOWERS FALLING (W. N.).—We think the flowers do not expand from the circumstance that they have hitherto been grown in a higher temperature, and you have given them a lower for flowering; consequently, the plants have received a check. Water moderately and afford abundance of light. We think they will do better when they become used to the temperature. Perhaps you have given them an overdose of liquid manure.

RETARDING CHRYSANTHEMUMS FLOWERING (Idem).—The only way that we know is to place them in a north aspect, but with plenty of light, and though that will retard them, you risk losing the flowers from frost, therefore you will need to have protection in readiness to save them from severe frost. We would house them and keep them cool by giving an abundance of air.

COAL ASHES AS A TOP-DRESSING (D. G.).—They would not be of any benefit as a top-dressing to light soils, nor would they increase fertility.

REMOVING HOT-WATER PIPES (Idem).—There is no mode of removing the "borings" that are used in making the joints, except by clipping

out with a chisel, a tedious and difficult operation, and not infrequently the joints or sockets are broken. It is best, we think, to cut the pipes with a file, and in such a place that they can be joined with a pipe having sockets at each end. Perhaps you will need to operate where the elbows are, then it would be best to break them, and you can free the sockets of the broken portion and add the additional length you require.

LASIANDBRA MACRANTHRA, BOUGAINVILLEA LATERRITIA, AND SOBRIALIA MACRANTHA (T. C.).—*Lasiandra macrantha* is the same as *Pleroma macrantha*. The *Bougainvillea* should have a temperature of from 55° to 60° at night, and from 60° to 65° by day from the present time to March, and in March you should start it if you wish for flowers in May. Give it plenty of moisture as well as heat; keep it dry during the winter, and prune it before starting, or in February. You will need to afford it a light position. It would be more likely to flower if pruned but little, and not overtopped. The old stems of the *Sobralia* ought not to be cut away, but should be allowed to die off naturally. They will not flower again, but from them you will have the parts for future flowering.

PERENNIALS FOR A BORDER (R. L. D.).—*Agrostemma coronaria*, *Ajuga alpina*, *Alyssum saxatile*, *Anemone apennina*, *A. coronaria* vars., *Anemone theca cruenta*, *Antirrhinum*, *Aquilegia Skinneri*, *Arabis alba*, *Anbretia deltoidea grandiflora*, *Aster alpinus*, *Campanula aggregata*, *C. pulla*, *Cheiranthus Marshallii*, *C. alpinus*, *Cyclamen coum*, *C. hederifolium*, and *C. hederifolium* album, *Delphinium alpestris*, *D. belladonna*, *Dianthus barbatus*, *Dianthus spectabilis*, *Draba aizoides*, *Erigeron grandiflorus*, *E. speciosus*, *Gentiana acaulis*, *Geranium sanguineum* and *lanceolatum*, *Gum coccineum grandiflorum*, *Helleborus niger*, *Hepatica triloba*, *H. angulosa*, *Helycathus anethystinus*, *Hypericum calycinum*, *Iberis saxatilis*, *Iris reticulata*, *I. attica*, *I. pallida*, *Lilium tenuifolium*, *Linum alpinum*, *Lycium alpinum*, *L. haageana*, *L. viscaria splendens*, *Lythrum roseum superbum*, *Meconopsis cambrica*, *Mysotis aizocica*, *M. sylvatica*, *Eriochloa macrocarpa*, *Orobanchis venosa*, *Oxalis tropaeolides*, *Prionias*, *Papaver alpinum*, *P. nudicaule*, *Puls Nelsoni*, *P. verna*, *Polemonium coruleum variegatum*, *Primula acaulis*, *Auricularis*, *Pyrethrum*, *Salvia nemorosa*, *Saxifraga aizoides*, *S. Andrewsii*, *S. juniperina*, *S. oppositifolia*, *S. cuneata*, *Sempervivum californicum*, *Silene Schaffii*, *Sisyrinchium grandiflorum*, *Spiraea Filipendula flore-pleno*, *Statice Gmelini*, *S. latifolia*, *S. minuta*, *S. tatarica*, *Symphyltum caucasicum*, *Thalictrum aquilegifolium*, *Trollius europaeus*, *Tussilago Farfara variegata*, *Veronica candida*, *V. Tenerum*, *V. alpestris*, and *V. hybrida*.

OLEANDER SCALE—GERANIUM LEAF BLACKENED (M. H.).—The Oleander leaf is attacked by scale, the Geranium leaf by the insect's secretion turned to a black fungus. Fumigation with tobacco will not kill the scale, nor will it be of any benefit to either. Pick off the scale from the Oleander with the point of a knife, and syringe the plant with a solution of soft soap, 3 ozs. to the gallon of water, and add ten drops of spirits of turpentine. The solution should be applied at a temperature of 140°, laying the plant on its side and turning it round, so as to thoroughly wet every part. Keep the solution from the soil. The Geranium will not need any application.

CHRYSANTHEMUM SENSATION FOR SPRING DECORATION (D. D.).—It is of no great value for the flower garden in spring. Your best plan would be to let the tops remain and mulch with partially-decayed leaves, cutting off the tops in March, and if the spring be warm the shoots may come up strong and have a good effect, but it is far more likely that they will be damaged by frost. For summer decoration take off the suckers in November, put them singly and place them in a frame, protecting them from frost in cold weather. It will answer just as well to save a few of the old plants, take cuttings from them in March, and place them in a gentle hotbed. When rooted pot them off and place them in a cold frame. They will form plants by May. Stop them to make them bushy.

PLANT FOR WALL OF ORCHID HOUSE (E. C. W.).—There are few plants that combine handsome flowers with variegated or fine foliage. *Passiflora trifasciata* may suit, as it has variegated foliage and ornamental flowers; but we should prefer *Cissus discolor*. The finest flowering covering of a wall that we have seen consisted of *Euphorbia jacquiniiflora* and *Passiflora quadrangularis*.

APHIS ON TYLIDIAS AND GESNERIAS (Croydonian).—The leaves sent have every appearance of having been attacked with the white aphid, which is most difficult to extirpate. Fumigation with tobacco is the only remedy we know, previously sprinkling with water the floor and every available surface, but not wetting the foliage.

CENTAUREA PROPAGATION (Idem).—The best way is to take off the side shoots close to the stem, pare the base smooth, and insert them in sand, placing them in a house with a temperature of from 60° to 65°. They may be inserted in summer in a frame, or in spring in a gentle hotbed. Perhaps spring is the best time. Be careful not to overwater, nor to keep too moist an atmosphere, otherwise the cuttings will damp. Keane's "In-door Gardening" will suit you. It may be had, post free, from our office for twenty postage stamps.

DRAINING A GARDEN (W. K.).—The cheapest and best method of draining is with tiles. The drains should be 4 feet deep if you can command sufficient outfall, and they ought not to be further apart than 21 feet, but much depends on the soil. If strong and clayey they may be closer than where the subsoil is gravelly or sandy. The prices of tiles and digging drains vary so much in different parts, that we can give you no fair idea of the cost. Consult some farmer or person accustomed to draining in your locality.

FUMIGATORS (A. D.).—Both these which you mention answer fully the desired purpose. Any dealer in such articles could supply you. No subsequent supplement has been published.

HEATING A GREENHOUSE (F. M.).—We think you will have heat enough in the house by the plan proposed. We presume that having the pipes near the back wall and so far from the ground level, is to suit the independent conical boiler that is to stand shut off by a glass partition in one end of the house; but for that the pipes would have had power if placed near the ground beneath the first floor stand. Most likely you could not manage that without somewhat sinking your boiler, as you cannot well take hot water below the boiler. Your shelf at the back seems also very high—6 feet from the ground. Why not have it a little above the stage in front? The pipes, if desirable, might come farther from the wall than 9 inches, but even at that the Vines stems would not be apt to suffer much. Vines would do well at the back if the soil were suitable and drainage. Without Vines, Camellias and Oranges, with an Acacia or two,

would do admirably against the back wall. The pipes would throw off more heat if placed on the same level instead of above each other.

AMERICAN BLIGHT *E. G., Leighton Buzzard*.—Slake some lime and add some salt, and apply with a brush. Some people add a little cow dung.—**W. F. RADCLIFFE.**

NAMES OF PLANTS (*Rev. S. L. Wilson, Prestbury Vicarage*).—*Lycium barbarum*, very commonly known as the "Tea shrub" in cottage gardens. (*H.*)—1 and 4 are the Lady Fern, *Athyrium Filix-femina*; 5, *Lastrea Filix-mas*; 3 and 6 are *L. dilatata*; 2, *L. spiculosa*, a variety of *dilatata*. (*M. R.*)—1, *Pteris flosma*; 2, a small var. of *Scolopendrium vulgare*; 3, a *Lastrea* not recognised by us; 4, *Campyloneuron lapathifolium*; 5, possibly *Cystopteris alpina*. (*G. P.*)—We do not identify your Fern, as it is not in fruit. Cannot you forward us part of a frond bearing sori? (*E. T.*)—*Campanula Pertenschlagiana*. (*M. H.*)—1, *Aster lavis*; 2, *A. Novi-Belgii*. (*H. J., Foto Island*)—1, *Clematis graveolens*; 2, *Aster Novae-Angliae*; 3, *Aster grandiflorus*; 4, *Artemisia*, apparently *Abrotanum*. (*T. B. W.*)—1, *Pteris longifolia*; 2, *Platyloma (Peltis) adiantifolia*; 3, *Adiantum nephrolepis*; 4, *Pteris serrulata*; 5, *Polypodium vulgare caribricum*; 6, *Nephrolepis cordifolia (N. tuberosa)*; 7, *Athyrium umbrosum*; 8, *Davallia Nova-Zelandiae*; 9, *Polypodium aureum*. (*M. D.*)—*Encomis punctata*, a Cape bulb. (*Marlow Cottage*).—The popular name, "Bottle Brush," is applied to the whole genus of the Horsesails, *Equisetum* of botanists.

POULTRY, BEE, AND PIGEON CHRONICLE.

POULTRY SHOW REPORTS.

I SEE that your correspondent, "SHROPSHIRE RECTOR," in the number for October 13th, gives me a gentle "dig," not a blow, still less an ill-tempered scratch, rather let me call it a sort of a pat, and then, fearing he has knocked off the skin, he puts on a plaster. Thus he says, "I am sure the value of 'our Journal' in a poultry-fancier's eyes would be greatly increased if we could have more detailed accounts of the poultry exhibited." Then comes the gentle dig or pat, "I do not mean such an account as that of 'WILTSHIRE RECTOR'S' journey to Stroud, in which the journey occupies about ninety lines, the fowls thirty, and the Pigeons eight." Then follows the plaster—"No offence to our good friend, whose letters are always amusing, and whose acquaintance I hope some day to make." These remarks afford me an opportunity of saying what I have been wishing for some time to say. As to my brother of Shropshire, I the more easily recover his pat, inasmuch as my opinion some years ago was not wholly unlike his. But now, after eight years' experience as a writer in this Journal, my opinion is, that reports to be readable, and especially to vary one from another, must deal more with the surroundings than with the birds themselves; and for this reason, that the birds exhibited are not only very much alike, but in many cases they are the very same birds. Thus, as one comes to a pen one says, "Ah! here are So-and-so's old Rose-combed Dorkings;" or, "Well, the Bristol Spanish are looking wonderfully well after so many journeys;" and so in a great measure it is throughout, except with the awkward squad—the birds sent by persons living near, and who do not understand poultry, and which birds are utterly unworthy of a remark. But if this be true of the fowls, it is even more true of the winning first-class Pigeons. A few fanciers have the best birds in the country, and win all or nearly all the prizes, and these birds are almost as well known at a show as their owners' names are known in the prize list.

But, again, "SHROPSHIRE RECTOR" remarks upon the reports of the judges (and by way, who so fit to report as those who have studied every pen in order to decide the prizes?), yet I can tell him that the best judge in the world gives usually in his reports but very few details, and he as well as I know the reason why.

Further, poultry in itself is not a very wide subject, and if one wrote diffusely every time of the Dorking's fifth claw and its position, or of twisted combs, or of removal of hairs from the face, or of a duck foot, we should make each volume of this Journal as alike as the covers, the dates only differing. Or as it was said by the poet of a Dutch garden, where—

"Each alley has its brother,
And half the garden just reflects the other."

But there is a further reason still. There is an authoritative "Standard of Excellence," at least one now received with great respect by all poultry fanciers. Let "SHROPSHIRE RECTOR" master that, and he will gain great knowledge of detail. But I do not see that we should print it part by part; to do so would be as great an error, to my mind, as to make the gardening department of the periodical an enlarged repetition of old Abercrombie brought down to the present time. I venture to think that the complaint of "SHROPSHIRE RECTOR" is that of a beginner.

I can further illustrate my meaning in this way. Where, until Mr. Blakston wrote, were Canaries? We had indeed occasionally an answer to an inquirer about long claws, or wheezing, or moulting; but how different now, when, during the last few years, we have had lengthy and excellent articles on Canaries. The reason is, I believe, because "W. A. B.'s" witty and readable papers have pushed forward the fancy. I consider that Mr. Blakston's account of the Crystal Palace Show of last February was one of the very best reports, if not the best, I ever read, and yet he always deals as much at least, or even more, with the surroundings than with the birds themselves. If a report were extended to many papers (one I think was even to six), and were it full of minutiae, I should break down in the reading, and read scarcely half.

"SHROPSHIRE RECTOR" mentions the Stroud report particularly. Now, I know the burden of care on the shoulders of committeemen, and never make complaints, especially if it be a first show. But as Stroud is specially mentioned, I must remark that after having paid 5s. entrance I never got a prize list at all. It was not printed by the time I left—viz., five o'clock, and one was sent to me by post afterwards. Such a state of things must cripple a reporter sadly. It is even a fact that all the prize cards were not on the pens when I left, and I should not have known which birds got the prizes in the Game classes but for the courtesy of the Rev. Mr. Hodson the Judge. Sad state of things indeed, but true nevertheless!

"SHROPSHIRE RECTOR" implies, unless I mistake him, that I write only to amuse; he will permit me to remark that I have a far higher aim, which is, by writing readable articles (readable by those who are not fanciers) to raise and enlarge the fancy, to extend it to those who have not as yet learned to love those beautiful birds which we love. But we must gain ears before we gain hearts, and I am sure an Eaton or a Brent, excellent in details though both were, never increased the Pigeon fancy, while I have seen on many a bookcase "The Dovecote," because its author knew how to write interestingly. Of poultry simply and solely, and its details, it would be impossible to write year after year, and many years in succession—the subject is not wide enough. Thus it is not unfrequently the case that ardent young poultry fanciers say to me, "What a pity there is no periodical for poultry only." I tell them it was tried years ago, and failed, and would fail again; the subject is too narrow. "Our Journal," taking in so many pursuits, fancies, and hobbies, succeeds, and for that reason. I have, during the many years I have written, come to know from the many private letters what class of papers readers are good enough to be pleased with, and without the least wish to be egotistical I must beg leave to add in conclusion this anecdote. A Pigeon paper of mine, "A Day at Devizes, and What I Saw There," written in the spring of 1865, happened to be copied into the county paper. I met for the first time soon afterwards a Wiltshire gentleman, who asked me "if it were true that I was the writer of it." I did not deny the soft impeachment. He replied, "Why you write so as to make people run off and buy fowls and Pigeons." I said, "That is just what I wish." I repeat, that I state this from no egotistical feeling, but to show that, although I am not "a dry detail dealer," yet I have, I trust, done some little good to the poultry world.—**WILTSHIRE RECTOR.**

As "SHROPSHIRE RECTOR" remarks, a report should contain something definite—something by which an absent exhibitor or breeder may properly estimate the relative value of his own and other birds. I have known cases where winning birds have been claimed by post or purchased afterwards from great distances, simply because they were winning birds, and upon arrival they were found to be indifferent specimens after all, thus annoying and disappointing the purchaser, and creating a feeling of distrust against the seller. I sincerely hope, therefore, that next week we shall not read of the winning pens of Light Brahmas at Southampton as being "a better lot than those of previous years," or "as a whole not so good as last year." Let us have some idea of the size, perfection in marking, and other excellencies, relatively, of the leading birds.

Mr. Wright's suggestion respecting commendations is well worthy of adoption. I fully endorse his remarks upon the entry fees at Birmingham. Let us hope that another year the Committee will consider the advisability of a change, abolishing the present subscription for a high entry fee. I can answer for many first-class pens in the west which, but for the high fees, would be sent singly, as both credit and the expense of carriage would prevent middling pens being entered.

Southampton Show will, doubtless, be a great success; but it really is too bad of Hampshire fanciers and the Committee to allow such breeds as Cochins, Chinas and Hamburgs to remain so far in the background. The proper number of classes, say three for Cochins and four for Hamburgs, would bring great improvement, and, I feel sure, cause no extra expense. How can the Committee expect to see any display of my favourite, the White Cochins, or, indeed, of either variety?

Speaking of White Cochins, it reminds me of another cruel schedule—the Crystal Palace. I had hoped that in this list we should at least see the prizes for all Cochins as tempting as at Bristol; yet, although Buffs and Partridge are very fairly handled, the poor Whites are left with a solitary class. The reason may be adduced that the variety never show in force; but, if such is the case, the cause is obvious—they are never offered the temptations so continually dangled before the eyes of other varieties. If a cup is offered by way of variety, it is always by subscription. White Cochins are becoming more generally cultivated, and breeders will not long rest contented with their miserable classification.

Some few weeks ago I appeared in your columns for cups for Cochins and Brahmats at the West of England Show to be held at Plymouth, but in consequence of the opposition by local exhibitors to their being "open," it is now determined to restrict them to Devon and Cornwall, especially as the particular breeds (Hamburgs having been added) require encouragement in the two counties. I may, therefore, openly thank those ladies and gentlemen who so kindly offered their assistance, although I intend to do the same by letter. The fact that Mr. Hewitt will judge gives great satisfaction, especially as last year two or three flagrant cases of "undiscovered" dyeing were observed.—JAMES LONG.

[We have now inserted all the worthy communications which we have received on this subject, and, bowing to the wishes of our correspondents, we have requested, and do request, all those who favour us with comments on poultry exhibitions to include in those comments notes on the especial superior points of the birds in the prize pens. Yielding thus far to our correspondents, we must also ask them not to expect all the information that they desire; we must ask them to consider who made the awards. If he is a man of known ability and integrity they may accept as certain that the birds to which he awarded prizes are good. We must also ask our correspondents to consider that adverse criticisms upon awards are painful to the judge, galling to the prizetakers, and irritating to those next below them. Bearing all this in mind, we will do our utmost to satisfy the wishes of our readers.—EDS.]

THE LONDON POULTRY AND PIGEON SHOW.

LAST week we briefly noticed the schedule of the above exhibition, but reserved a fuller review for our present issue. We are very glad to find the Committee offering such a valuable and at the same time so comprehensive a prize list. They are evidently endeavouring to make this show at the Crystal Palace one of the first, if not the first, of its kind in the kingdom, and with the vast resources and conveniences to be found at the Palace, we see no reason why they should not succeed if only exhibitors and the public give them the support they deserve.

The Committee have acted wisely in holding the Show simultaneously with the Cattle Show, for those interested in the one will mostly be interested in the other. All the prize birds are to be sold by auction on the Wednesday (Dec. 7th), and should any bird realise more than the catalogue price the excess is to be equally divided. This is a move in the right direction, as all will then have a fair chance of purchasing any prize bird they may choose. Most of the poultry have separate classes for old and young, the old birds to be shown cock and hen, and the young as single cockerels and pairs of pullets. For each class there are three prizes of £3, £1 10s., and 10s., and a silver cup or piece of plate, value five guineas, for the best pen in most classes. Light Brahmats have three cups. Spanish are treated more liberally than any other variety, as they have two five-guinea cups for old birds, and two of six guineas and four prizes for young. Hamburgs are shown cock and hen together, and all compete for a cup. Game are any age, cocks and hens, but only one hen this year. Polish are divided into three classes. Malays have as many prizes, and no doubt "the real big birds" will appear. Brown Red Bantams have a cup for the best cock or pair of hens. There are three selling

classes—for a single cock, two 10s., a cock and hen—with four prizes for each class. Black Duck, Ornamental Waterfowl, and Pheasants have each a separate class.

The Pigeons are divided into no less than fifty-one classes, with seventeen cups, and we expect to find the most interesting, the greatest, and the best show of Pigeons ever seen, as we believe we are correct in saying never before was such a complete schedule issued. Pouters are divided into fourteen classes—Carriers eight, Tumblers five; each of these varieties, also Barbs, have a cup for birds bred in 1870. Jacobins and Fantails compete together for a cup. Foreign Owls and Dragoons have one for the best pair. There are several novelties, amongst which is a cup for the best collection of four pairs of Pigeons, exclusive of Carriers, Pouters, and Tumblers; the latter have one for the best four pairs, and another is offered for the best pen of six working Antwerps. Each of these classes will prove very interesting.

The total amount offered for competition is between £600 and £700, with nearly forty cups. The entries close on November 12th.

FORM VERSUS WEIGHT.

I QUITE agree with your correspondent, Mr. T. E. Kell, especially as to Turkeys, Geese, and Ducks. They won by size at the past, and it appears will do so at future Birmingham shows. I have proved by experience that such birds are of no use, at least in the following season, for breeding purposes. Facts are stubborn things. I had a Goose a few years ago fed up to the so-called Birmingham standard. She laid fifty eggs one season—a fair lot for a pudding, but not one was fertile. I can assure the Birmingham Committee I have not the inclination to destroy valuable breeding fowls to try to win laurels even at a Birmingham show. I have known in this county judges depending on the scales rather than, as it ought to be, form versus weight. Once in particular I was exhibiting my one-eyed Goliath at one of those local shows, and was annoyed at finding that the scales were to decide; and, as I afterwards told the judges, I was disgusted with any man pretending to be a judge not deciding according to his own judgment. They replied, "Just what we thought before weighing." But that is not it. I object upon principle, and interest as well, for such decisions give a premium to overfed fowls, besides making them valueless as breeding fowls.—O. A. YOUNG, *Middle Street, York.*

INQUIRY.

IN reply to the inquiry of "EAST YORKSHIRE," which appeared in your last impression, that gentleman has been made the victim of an act of unprincipled trickery. His informant turns out to be an unscrupulous person of the name of Holmes, who, seeing his opportunity, determined to effect a sale of his own "inferior stuff," even at the cost of honour and truth. In reference to my place being infected with "several kinds of disease" that is simply untrue, as the only complaint with which my fowls have been troubled has been a slight attack of the roup, which I attribute to the late wet weather, but of it they are now quite clear. And concerning the quality of my stock, I would just say that during the very week in which "EAST YORKSHIRE" visited Driffield I sent out forty birds on approval, all of which were kept, and that I have sent birds to our best breeders and fanciers for as much as £3, £4, and £5 per pen repeatedly; that I still have on hand for sale over a hundred pure-bred poultry and Pigeons of various kinds, many of them prize fowls of high quality; and that I am the only person in the town who owns a pen of first-prize Cochins. "EAST YORKSHIRE'S" informant played out his little trick very well for himself, since he succeeded in selling that gentleman a pen of second-rate birds for a first-rate price. I seriously caution "EAST YORKSHIRE" against publishing false reports respecting the state of my place and the character of my birds on the mere word of such a person.—J. PUNSON, *Driffield.*

IPSWICH POULTRY SHOW.—We have just received a schedule of prizes to be awarded at this Show. It is most liberal in its construction, offering five-guinea cups or pieces of plate, &c., for Game, Drakes, Spanish, Brahmats (Light and Dark), and Cochins; a three-guinea cup, &c., for Hamburgs, and the same for French and other varieties. A notable feature is a special prize, value £3 10s., for the best pen in the "Selling Classes," either a cock and hen or single cock. Bantams are

also well considered, having a five-guinea cup confined to their classes. For Pigeons there are nine classes, including Carriers and Barbs bred in 1870. Canaries not only have ten classes, but a special plate prize of £3 3s. for the winner of the greatest number of points. Mr. Hewitt and Mr. Willmore are secured

as censors. The Great Eastern Railway Company have liberally consented to return birds not sold free to any station from whence they received them. With these inducements, the Ipswich Show ought to have more entries than it has hitherto had.

THE BARB.

The accompanying engraving is a portrait of a Black Barb cock, four years old, and of great merit, having won many prizes at important public shows. It was specially portraited for this Journal. In giving our opinion upon this beautiful variety of Toy Pigeon, we wish to be as explicit as possible, so that our opinions may be of service to the uninitiated.

We are not assuming too much in saying the Barb requires as much care and judicious selection as does the Almond,

Carrier, and Pontor, and we call the attention of young fanciers to the following, as being the results of careful study.

The Barb attains perfection when about four years old. It should have a broad flat skull, gradually receding from the front of the head to the back; a short, thick, and strong bill, resembling that of the Bullfinch. The bill should not measure more than $1\frac{1}{2}$ inch from the point to the centre of the eye; the upper and lower mandibles to be of equal thickness or strength,

with a well-spread wattle on the upper, while that of the lower is notched from its point right into the feathers encircling the eyelash. The colour of the eye is white or pearl, which terms with fanciers are synonymous. If of any other colour it ought to be a disqualification. The cere, or wattle, of the eye is large, very thick, and of a deep red colour, circular in form, having an equal quantity at the back as at the front, or similar to what is termed a rose-eye in a Carrier.

The form of the Barb is short and strong, causing a rather heavy appearance. The neck slender, gradually thickening to a well-developed breast. The butts of the wings are prominent; their flight feathers are rather longer than those of most other

varieties of Toys. A noticeable point in the wings of this bird is, that their under or second flight feathers protrude considerably above their back from the upper or flight coverts.

There are five recognised colours in this variety—viz., Black, Yellow, Red, White, and Dun. The last-named is always dirty and disagreeable to look at, and is the result of injudicious crosses of the various colours, therefore has not that metallic lustre which so adorns a Barb in good feather, and without which they ought not to be admitted into a show pen.

Purity of colour should be regarded as indispensable. We therefore point to the desirability of breeding from birds matching in colour—viz., Black to Black, Yellow to Yellow, &c.

always having due regard to their parentage and properties. Colour has been so sacrificed by breeders for head, eye, and bill, that one never knows what colour to expect their progeny will be until they are feathered. Often Yellow and Red are bred from Black. When such is the case you will invariably find either colour is tinged on every body feather with black. Their flight feathers are either a dirty dun, or tinged with grey along the quills; their tails having several white feathers in the middle of them, or else on the top of the rump. Should one be of a passable colour you will generally find a black band at the end of the tail. By pairing Black and Yellow, or Black and Red, you will most certainly produce the same results. Red and Yellow is the only cross that any good is likely to arise from. By this cross the red is impoverished, but the yellow is obtained of a sounder colour.

If a breeder would consider for a moment he would know that Black has been the only colour that has gained by the mixture. By crossing any self-coloured bird to a Black, the latter is often improved, and the purity of the former destroyed. What is more disagreeable than to see your pet of two shades, whereas the Barb is a self-coloured bird? We might as well try to breed Mottled Barb as to have the tail and rump of a different shade to their body. However well bred such may be, they will never be fit to enter successfully into competition with birds of sound colour possessing equal merits in general.

Good Whites are very scarce, and have a dark eye—that is, the pupil almost indistinct from the iris. Several breeders have tried to introduce the pearl eye into them, but to the present time we have not seen any having so good a quality. In other respects they should be equal to those of other colours.

Barbs are hardy, docile, birds, flying but little when at liberty. As a rule, they are prolific breeders, but require assistance in bringing their young to maturity, as they generally seek fresh nests when their young are nine or ten days old, up to which time they feed well. We strongly recommend this variety to any who think of increasing their stock, as the Barb is not receiving so much attention as the bird deserves from the fancy at large.—BIRMINGHAM COLUMBIAN SOCIETY.

CLEAN-LEGGED WHITE BANTAMS.

In your Journal of September 1st, I wrote respecting White Bantams as being beautiful birds fast declining; we seldom see them in a class by themselves, still there are a few committees who hold out some encouragement for them. As Mr. Cambridge kindly remarked, they did not pay as a class. In my opinion we ought not to strike out a class from the prize sheet because it happens to be a failure in a pecuniary point of view; our prizes are offered, or should be, for the encouragement of the various breeds of poultry, and to aid in bringing them to the highest point of excellence. I say White Bantams pay as a class at some shows which I could name. They have a very respectable class at Newark and various other places, but in Scotland, I think, there are more classes for them than here. Mr. Cambridge wished "WHITE BANTAM" to communicate with him, and he would endeavour to retain the class for White Bantams at Bristol next Show. I am glad that communication has led to the result wished for, and that they will be tried there again.

My chief object in writing is to make known to all White Bantam friends and fanciers that we are to have a White Bantam class at Manchester Show, to be held, as usual, at Belle Vue. The prizes of £2 and £1 are offered in the prize list, which is being subscribed; but it is our intention to offer a silver cup for the first prize, the £2 offered as the second prize, and the £1 for the third prize. I have the pleasure to state that the following have already subscribed towards the above object—viz., "A Friend of White Bantams," 30s.; myself ("WURRE BANTAM"), 21s.; Rev. F. Tearle, 5s.; Mr. J. Watts, 10s.; and Mr. Edwin Pritchard, 5s. I cordially invite all fanciers to come forward with their subscriptions as soon as possible, so that we may have the prizes stated before the entries close. We know that Messrs. Jennison have one of the finest places in England for the purpose of a show, with an excellent staff of assistants. All, therefore, may rely upon their birds being well cared for in every respect, and returned, perhaps better than if they had stayed at home. Subscriptions for the above cup and class will be received by—SAMUEL J. ASHTON, *Roe Cross, Mottram, Manchester.*

HATFIELD BIRD SHOW.—I see that Ha'field again opens to the fancy, and I am sure, from the care taken of all our birds

last year, together with the improvement in the prizes and the low scale of entry fees, it should obtain the patronage of all my fellow fanciers. From a note received, I see all birds required, will be sent to Stockton by night mail for the show there the following day.—THOMAS FLETCHER.

SCARBOROUGH ORNITHOLOGICAL SOCIETY'S SHOW.

THE second annual exhibition of the Scarborough Society was held on Wednesday and Thursday, the 19th and 20th inst., and was a signal success with respect to both the number and quality of the birds staged. The Temperance Hall, the room in which the Show was held, is admirably adapted for the purpose, being well lighted, and, what is of the utmost importance, well warmed. So far as I could see, everything that prudence and forethought could devise had been done to secure a watchful attention to the stock, and it is at any time pleasing to be able to bear testimony to a fact which must secure the confidence of exhibitors generally, who, in sending valuable birds to any exhibition, place grave responsibilities in the hands of committees.

I shall confine my remarks to merely a slight review of the different classes, as time will not admit of my doing more, though I should have felt disposed, under more favourable circumstances, to have made my trip to Scarborough the text for a history of my "outing"—I think that's the word. A correspondent some short time back said he liked a visit to a show at a distance to assume the character of an "outing," and not merely to resolve itself into a statement of how A was first, and B was second. Another correspondent hit out straight from the shoulder, it was a shot, and said he did not care to read a column of extraneous matter, and then a half-dozen-lines notice of the show. It was something to that effect; I am only writing from memory. Many men have many minds, and among the thousands of readers into whose hands the "Journal" falls every Thursday, there will be as many who will take an interest in the "outing," as in the show. It takes many a reader home, too; and the greatest pleasure one has in writing is, that apart from a dry statement of facts which can interest comparatively few, there is the knowledge that some remark, some line or two, may make an otherwise dull page shine with a cheerful light. Every hobby is interesting to its own individual admirer, and if you love your hobby, make it as attractive as you can, and induce others to love it also.

Scarborough saw many new birds shown for the first time this season. To these more interest attaches than to birds of known character. Moore & Wynne brought out a splendid Clear Jonque Norwich, which had no difficulty in disposing of its opponents, Irons being a good second, with Simpson well up. Those who do not understand about Canaries will not know what all this means, and who Moore & Wynne, or Irons, or Simpson are. Well, I cannot help its being dry to you, it is not so to everybody. Some old fanciers (do you know what I mean by a "fancier?") will read it with immense interest. In Clear Buff Norwich, Moore & Wynne were first again, with a fine specimen, quite a star, and Simpson second with a good bird, which must visit the laundry before being sent out again. Good birds, if dirty, can never win against possibly inferior ones which are clean. When I say clean, I mean *clean*. In Evenly-marked Yellow Norwich, Mills's little wonder suffered defeat at the hands of one of the best Variegated Jonque Norwich I ever saw. It is a bird of good size and rich in colour, rather heavily but well marked. There is a very trifling difference in the absolute number of dark feathers in each wing, but it is quite unappreciable to the eye. The eye marks are rather heavy, but remarkably even in size and shape. What defects it may have, if it have any, it can afford to give away and still win. Mills's bird, however, is not yet quite fit, and what may be the result when they meet again I do not know. I hope it may be at Middlesbrough, where Mr. Barnesby is going to judge, to whose decision I shall look forward with much interest, and hope we shall have the pleasure of shaking hands. Moore & Wynne's bird, which was third, is beautifully marked, but though in faultless condition was deficient in colour. In Evenly-marked Buff Norwich, Moore & Wynne were first and second with two fine specimens, the first-prize bird being the same which won the silver cup at the Crystal Palace last Show. The Ticked classes contained, as they always do, some richly-coloured birds. The crests were extra good, including all varieties, Moore & Wynne being first with a fine marked and crested Buff cock. Mr. Calvert, of York,

showed a sweet hen, clear Buff with dark crest, which when more advanced will require some beating.

The less said about the Belgians the better, only one being in show condition, and it was by no means a bird of high character. A Buff bird (I think No. 106) shown in a Norwich show cage would have taken the first prize if it had had room to stand up. The Yorkshire classes were good. There was the usual sprinkling of Norwich among them, but the number is decreasing. The winners were good, Mr. Luke Belk, of Dawsbury, being first both in clear and marked birds. Lizards were both numerous and good, Mr. James Taylor, of Middlesbrough, and Mr. Mills, dividing the honours between them. Cinnamons were first-class, Mr. Irons taking both prizes with two Jonques, with excellent birds behind him. In "Any other variety," Sir W. H. Fielden was first with an immense bird, copy bred, but with a plain head—for immense read huge.

Evenly-marked Goldfinch Mules were a poor sample. Mr. Hawman and Mr. Stansfield showing the only two strictly in accordance with the schedule. Dark Mules were backward. Among twenty-six "cages of four," some nice birds were shown, forming a very attractive feature of the Show, Scarborough winning first honours in the person of Mr. Houghton. Linnet, Goldfinches, Skylarks, Bullfinches, &c., made up an interesting collection of British Birds, which I should like to see more extensively exhibited. And I saw other pretty birds at Scarborough!—W. A. BLAKSTON.

NORWICH.—Clear Yellow.—1, Moore & Wynne, Northampton. 2, T. Irons, Northampton. 3, R. Simpson, Whitby. Clear Buff.—1, Moore & Wynne. 2, R. Simpson. 3, R. Hawman, Middlesbrough. ANY VARIETY OF BRITISH BIRD.—1, W. Harland, York (Bullfinch). 2, E. Stansfield, Bradford (Brambling or Mountain Finch). 3, O. Lawson, Scarborough (Goldfinch).

JUDGE.—Mr. W. A. Blakston.

BIRMINGHAM PHILOPERISTERON SOCIETY.

On the 25th and 26th inst. the fifth annual meeting of the above Society was held in the Athenæum Hall, Temple Street, Birmingham, and certainly public interest has never before been so completely enlisted nor better gratified; for although numbers of the visitors had travelled hundreds of miles solely to attend the Show, in every instance entire satisfaction was expressed at seeing not only one of the best collections of adult Pigeons, but likewise a competition of birds hatched in the present year that for their age have never been equalled. Almost every noted breeder of fancy Pigeons either sent birds for competition, or attended with the intention of purchasing fresh blood to improve his own stock. Perhaps one of the most noteworthy features of the whole Show was the *Bird* classes, the remarkably well-developed adults of Captain Heaton calling forth repeated expressions of admiration from all connoisseurs; nor were the young of this variety less remarkable for their perfection of condition and faultless characteristics. The *Carriers* were also admirably shown, and mostly in first-rate health and feather. *Fantails* were remarkably good, but several pens were sadly injured by packing in too small baskets. The Almond *Tumbler* shown by Mr. Adams, of B. Verley, were not bent in skull and in good feather, but the mode of selection of this gentleman's stock for *show alone* was open to improvement. *Tumbler*s were very fine, and the foreign ones were perfect gems. Some first rate English Owls were also on view. The *Turkots* were the best collection of high-class birds ever shown in Birmingham, and a remarkable feature was that every colour was well represented. For *Dragoons* the meetings of this Society always ranked high, and on this occasion so perfect were they, that one of the oldest exhibitors admitted it was almost impossible to hope for success in such competition, that he was glad he had seen them, for he should have been hopelessly dead had he entered his birds, which he had hitherto considered invincible. The *Intervary*s certainly did not develop so much character as at some previous meetings, many being sadly too long in head and spare in bill.

In the classes for flying *Tumbler*s the improvement was very marked indeed, more particularly in the matching to feather of the birds, and the perfect condition in which they were penned. In *Yellow Dragoon*s the cup fell to the pen 262, shown by Mr. Frank Graham; they were, perhaps, one of the most faultless pens ever exhibited, and for colour

quite unexceptionable. In Class 60, for a single Pigeon of any variety, Captain Heaton pretty well swept the board in a heavy class, taking the first, second, third and sixth prizes with excellent Barbs, and also the fifth with an English Blue Owl of great merit; Mr. Harry Adams, the only other successful exhibitor in this class, having a really sound-leathered Almond. Mr. Yardley exhibited two cages of excellent Carriers and Almonds, of about twelve birds each, not for competition, which added much to the attractions of the Show.

The *Fancy Toys* were public favourites; and when we state *Satinettes*, "Bluettes," quite a new and exceedingly chaste variety, *Lahores*, *Scandarooms*, *Maned Pigeons*, *Egyptian Swifts*, *Isabels*, *Archangels*, *Starlings*, *Priests*, and *Shields*, were all well shown, it is scarcely to be wondered that six prizes were awarded, and certainly as many more might have been with justice given.

BIRDS OF 1870.

CARRIERS.—Black.—1 and 3, F. Smith, Selby Oak. 2 and 4, R. W. Nightingale, Aston. *he*, J. Linnett, jun., Coventry; R. W. Nightingale. *Dun*.—1, G. F. Whitehouse, King's Heath. 2, J. Mr. Edward Hewitt, Mr. Henry Yardley, and Mr. Wm. Walthew, of Birmingham, were the Judges.

SHEFFIELD ORNITHOLOGICAL SOCIETY'S SHOW.

The first annual Exhibition of this Society was held from the 21st to the 24th inst. The attendance was not so large as desirable, but considering the bad weather, there was not much fault to find. The Show was very attractive, and the room was well ventilated and heated, making the specimens warm and comfortable.

Pigeons.—Carriers.—1, W. H. Mitchell. 2, W. Harvey. *he*, E. C. Streech. *Pouters*.—1 and *he*, W. Harvey. 2, E. Brown. *Barbs*.—1, W. Harvey. 2, H. Yardley. *Tumbler*s.—1 and 2, W. Harvey. *he*, E. Brown; H. Yardley. *Jacobins*.—1 and 2, W. Harvey. *he*, J. Smithers; H. P. Ryland. 3, F. Brown. *Fantails*.—1, J. F. Lovesidge. 2, W. Harvey. *Doves*.—1 and 2, W. Harvey. *Kunts*.—1, H. JUNCOS.—*Pigeons:* Mr. James Smith and Mr. Henry Brown, of Walkley. *Canaries:* Mr. George Tuckwood, Nottingham. *Rabbits:* Mr. Grindley, Sheffield.

EXPERIMENTS WITH FOUL BROOD.

I HAVE this autumn been amusing myself with experiments in the way of foul brood, and I regret that some one more able than I am has not taken up the subject, as I find myself incompetent clearly to explain the results of the experiments which I have made. These experiments were undertaken in order to prove the fungoid theory, and to my own satisfaction I have proved it; but, as I have already said, I am not able to describe them in technical terms, nor to make common terms supply the place of technical ones. I will, therefore, merely describe one experiment, which may, I hope, stimulate others. It was my last essay, and was made by taking two half-cupfuls of sweet milk, and impregnating one-half with a modicum of foul-broody matter about the size of a No. 1 lead shot. In twelve hours the one impregnated became sour, and in forty-eight hours the curd was separated from the whey, and in a few hours a fungus like a vinegar plant became visible on the surface of the whey. At the end of two weeks it became a very thick gelatinous substance, the curd all this time remaining sweet. At the end of three weeks acetous fermentation and putrefaction set in, and there was visible round the edges a yellow substance, the smell, though stronger, being not unlike that of foul brood, and when viewed through a microscope millions of spores were seen, similar to those of foul brood. The other half-cupful of milk underwent no change further than that which happens in ordinary sour milk.

These experiments, although they may not instruct your readers, will, I hope, be the means of stimulating others to solve the problem of what at this moment not only threatens to destroy insect but human life.—A LANARKSHIRE BEE-KEEPER

POST ENTRIES AT CANARY SHOWS.—Newcastle has, as may be seen from our advertising columns, extended the time of making entries. We think it well, as the time between the close of entries and the Show is unusually long. But would it not have been better to have named a reasonable time, and so have obviated this necessity?

OUR LETTER BOX.

BAILY'S PILLS (Isa).—Write to Messrs. Baily, 113, Moimt Street, Grosvenor Square, London, W.

MONMOUTH SHOW (T. A. D.).—As the Committee did not think it of sufficient importance to advertise, we conclude it was not worthy of special notice. Committees may do well to consider this extract from your letter:—"I frequently see in your paper notices of shows that have not been advertised previously, which prevented me from exhibiting many times this season. This I should have done had I known there was a show at such and such places."

TUNDRIDGE WELLS POULTRY SHOW.—We are informed that the commended pen of Spanish chickens belonged to Mr. J. Francis, and not to Mr. Hose.

SILKIES FIVE-CLAWED (M. A. F.).—It is not a blemish. So far from it, the five claws are often found on the best specimens. It must be clearly understood, that in showing a pen the birds of which it is made up must all have the same number of toes, whether four or five.

SWELLING UNDER A HAMBURG'S EYE (Northern Subscriber).—Your bird is suffering from cold, and if neglected this will turn to roup. Wash the feet well with cold water and vinegar. Give him Baily's pills, and camphor pills once or twice per day, according to the symptoms. He wants watching closely this damp weather, when the symptoms become aggravated quickly. Both huckle and saddle of a Silver-spangled cock should be perfectly clear, but the principal feathers should be tipped with black.

ROUEN DUCKS' PLUMAGE (F. G. S. R.).—We cannot quite understand your question. All Rouen Ducks should be the colour of wild Ducks and they are always dark. We consider light plumage a defect, and any white is inadmissible, save the ring round the drake's neck; this should be small.

ALMOND TUMBLERS (A Subscriber).—We cannot recommend anyone. Write to Mr. J. W. Ludlow, Secretary, Columbarian Society, Vauxhall Road, Birmingham, and ask him. Enclose a stamped and directed envelope.

FANTAILS LAYING AND SITTING BUT NOT HATCHING (J. P. Davies).—Your place for your Pigeons is suitable. If the eggs are clear at a week's end, shine them up by a candle and you will see; then it is the male bird's fault—he is too old. This is the most probable cause. If the eggs are fertile, they may have rolled from under the hen, or been in some other way chilled. You, of course, make a nice concave nest of straws cut 2 or 3 inches long. Bread and potatoes are not fit for staple food for Pigeons, but they peck a little now and then with relish. Oats are not good either.

POLE-HOUSE FOR PIGEONS (An Old Subscriber).—A pole-house in the middle of a yard, unsheltered from the wind, is an unsuitable abode for Pigeons in the winter, and it would be much better to find out some corner of a loft over a stable, &c. All pole-houses, however situated, are cruel places to force Pigeons to live in. The birds are scorched to death in the summer, frozen in the winter, and are usually of little profit to the owner, as there is no fit nest secure against wind and rain in which to rear their young; while, on the contrary, if but 2 feet deep within a building can be given them, with holes outside to match each division of the inner woodwork, full success may be looked for, and the birds have a comfortable home. There must be a landing-board outside such building level with every row of holes.

TURTLE DOVES (Bullfinch).—They should be entered as British birds.

PRESERVING PLUMS WITHOUT SUGAR.—Take any kind of plum (if not quite ripe all the better), gather them when dry, wipe each fruit, place them in wide-necked bottles, then tie over the mouth of each bottle two pieces of bladder separately—i.e., at two tyings. Place the bottles in a boiler in cold water up to their necks with bay to keep them from jarring. Boil till the plums begin to swell, say fifteen or twenty minutes, take off the boiler, and let the bottles remain in it till cold, then remove the bottles to a dry closet, where they may remain for one or two years always fresh and good.

METEOROLOGICAL OBSERVATIONS

In the Suburbs of London for the week ending October 25th.

COVENT GARDEN MARKET.—OCTOBER 26.

We have a fair attendance of buyers, but business generally is far from encouraging, there being a great excess in the supply, and prices remaining nearly stationary. The Potato trade has improved, and there has been a slight advance in the first qualities. Pears comprise Marie Louise, Glou Morceau, Duchesse d'Angouleme, and Bauré Clairegain, with inferior varieties; Apples, Ribston Pippin, Cox's Orange Pippin, Blenheim Pippin, Kerry Pippin, and Fearo's Pippin.

From observations taken near London during the last forty-three years, the average day temperature of the week is 52.2°, and its night temperature 35.9°. The greatest heat was 63°, on the 5th and 6th, 1834; and the lowest cold 17°, on the 9th, 1864. The greatest fall of rain was 1.02 inch.

NOTES MADE DURING A TOUR IN IRELAND.

No. 1.

IRELAND, our fair sister—the green, the Emerald Isle!—we gardeners of England know little of your land, and yet Ireland is very near to us, and very dear to us. Dublin is but eleven hours from London, and yet Ireland is too little known to us, and less understood. Why is this? It would indeed be difficult to tell. There is but a narrow strip of water that divides us, and yet we hesitate to pass across. Many of us, although we boast of our supremacy of the seas, have still a secret dread of sea sickness—of the horrors of crossing the proverbially shaly Irish Channel, and so many of us remain at home, and remain ignorant of the beauties of lovely Ireland, and of the warm hearted natures of the Irish people.

We are all pretty well informed that Dame Nature has been wondrously bountiful to the Irish Isle, endowing her with a genial climate and with rich and fertile soils. We have, however, but a poor knowledge of what that really means, or of the vast magnitude of the capabilities of the country. It requires seeing her to understand.

We, in England, have strange and crude notions that Ireland is a land half desolate and neglected—centuries behind our own—with a people poor, oppressed, and discontented—with landlords harsh and tyrannical, screwing the life-blood out of the land! Can there be greater delusions? We read at times, it is true, some sad accounts of the bad feelings existing between landlord and tenant, but these are very exceptional, and in no way compromise the great body of the people, landlords or tenants. As for the Irish landlords, take them as a class, I believe them to be extremely indulgent. It having been my fortune lately to visit many of their establishments I say this much candidly, that they contrast very favourably with our own in many ways. There are numerous exceptions, of course, and the worst of all are the absentees, a class which are far too common.

Are the people oppressed? No, decidedly not. Are they poor? No. Although they seem so in their miserable hovels of dwellings, and their dirty tattered garments, yet they are by no means poor. Speak of poverty in Ireland and you give deep offence; besides, it is not true. Work is plentiful in Ireland, and workmen scarce. Wages are generally as high as in this country—from 2s. to 3s. per day, and during harvest far higher, with many accompaniments which the labouring class of this country do not have.

Is Ireland poor? This cannot be when the farmers of Ireland have been able to lay by within the last few years, as stated from official returns, several millions of money. Are the people discontented? This cannot be denied, yet I hope the causes are fast being removed, for a more joyous, hearty, kind-hearted people does not exist; but into this it is not my business to inquire—my object in visiting Ireland was to observe its gardens and gardening.

In passing through the country I could not help noting

everywhere the extremely well-made and well-kept roads, under the care of Government, I believe, and how extremely appropriate is the title of the green and Emerald Isle! for green it is in truth. Such depth of verdure, such extent of landscape, all of the most lovely green, nowhere have I seen except in Ireland. How vivid, how marked was the contrast of the beautiful green and rich grassy meadows, and the lovely green trees, to those of our own country this season! Whilst we in England have been parched up—almost without a blade of green—in Ireland vegetation was triumphant—grass abundant, root crops, Turnips, Potatoes, chief of Ireland's food, everywhere most excellent. The great extent of rich pasture land in some of the counties, as in Meath and Kildare, is something marvellous, entire and immense tracts of land being like one vast grazing field, broken only by the hedgerow trees. We envy Ireland also her charming lakes and their rich and lovely scenery, the magnificence of her trees and tree landscape, and the grand and extensive parks which surround the seats of her landed nobility. Widely apart as these seats may be the one from the other, they nevertheless present considerable uniformity of character. The various sites are remarkably well chosen, giving most extensive views of the surrounding district.

The style of the mansions is in general plain Elizabethan and baronial, with most extensive and well-designed parks and gardens. The parks and the trees around the Irish nobleman's abode are quite features of the country. The gardens, too, seem to have been laid out originally with considerable skill and taste, and generally on an extensive scale. I do not speak here of hothouses, which belong more to the present age, but of the art of landscape gardening and designing, and I feel bound to observe that there are evidences in these old places of a fully higher calibre of gardening than is common at the present day. I met with many exceptions, of course, which I shall duly notice, yet I could by no means blink the fact that gardening in Ireland, as in our own country, is running too much in one groove, and, to my mind, that groove is a very narrow one. There is a growing tendency for having all things under glass, for expensive stove and hot-house plants, for staring ribbon borders, and great blazes of gaudy colour, instead of quiet beauty of form and simple elegance. In our rage after all this we are forgetting much that is pleasing and lasting in the beauty of our hardy plants and trees, which give such universal and continuous pleasure.

Of the principal features of Irish gardening I would just notice the unusually fine collections of stove and fine-foliaged plants, and the general excellence of the specimens, with the apparent great interest taken in their cultivation. I met with these in very unexpected places. In many establishments I fancied the same means would have been far better expended elsewhere—whether these were pet subjects of the employers or of the gardeners I cannot say. It struck me, however, as ill-regulated in several instances where the employers reside but little, and where labour seemed to be sadly scant—with fruits and other more permanent subjects greatly neglected—to

discover so many of these expensive plants. In our stove and ornamental-foliaged plants we have, no doubt, the most beautiful forms of vegetation, and being so, I think they should be but sparingly introduced, or not at all, unless the other portions of the garden are in harmonious keeping. In such places as Powerscourt and Mr. Bewley's, at Blackrock, the hot-house plants formed a fine feature in perfect harmony with the whole; but I see no beauty in stove plants which have to be reached through other portions of the gardens much neglected.

The modern style of flower gardening in Ireland is following much in the same direction as in England—endless bands and stripes of gaudy colours. We cannot but admire such blazes as we sometimes see, when well done, but too often they are extremely repulsive. At Mount Merrion, near Dublin, the display of tricolor and bronze Pelargoniums was magnificent in the extreme, far exceeding in their brilliant colourings and general effectiveness anything I could have anticipated in the flower garden. With us bronze Pelargoniums planted out of doors are in general dingy and dull, but at Mount Merrion they were more brilliant than we have them under glass. Possibly a good deal of this superior excellence may be attributed to the more soft and gentle humid atmosphere of Ireland, which is more favourable to leaf-development and coloration than our own climate.

I must here enter a word of protest against the employment of coloured-leaved Beet amongst flowers to such an inordinate extent as was the case in Ireland. Nothing, possibly, could have shown worse taste than in many of the instances where it was used. The plant has a very striking and unique appearance, and should be used sparingly. I do not object to its use now and then. It is well adapted for mixing with other fine-foliaged plants in large beds, as against the white-leaved Centaurea, or even the yellow Pyrethrum; but, as I observed it in several instances in small beds along with Verbenas, Mrs. Pollock Pelargonium, &c., it had a most detestable appearance. The dry season had in several instances prevented the other occupants from growing to any considerable size, so that the dark-coloured leaves of the Beet, which seemed to thrive everywhere, gave some of the gardens around Dublin the appearance of fields of Mangold. A far finer plant having much the same colour of leaf, and which seems particularly well suited for Ireland, is the Iresine Lindenii. The older variety, I. Herbstii, seemed in Ireland to take the place of Colens Verschoffelti with us, which I was rather surprised to find does not succeed in Ireland; at all events I only saw it on one or two occasions.

The Zonal Pelargoniums seemed to find a happy home in Ireland, and one of the most telling and favourite varieties was no other than Amy Hogg, her pleasant lively face lighting up many an Irish garden.

The great number of Irish Yews, studded over the Irish gardens like military sentinels in their unbending stiffness, was also another feature that attracted my attention. At Carton, Maynooth, they were grand and imposing.

Fruits are on the whole not quite so well represented as I had expected to find them. Grapes were in many places extensively grown and well, although I saw nothing sensational. Pine Apples seemed to be but little grown; at all events I saw few in my travels. Peaches were, as a rule, excellent and well cultivated. Orchard houses seemed to be at a low discount since Mr. Bewley's famous ones have succumbed. Outdoor fruits were extremely abundant, and in many gardens I found very fine collections. Pears on pyramids in the gardens round Dublin were very fine. If a little more attention were paid, Ireland would be a great fruit-producing country. In many districts the climate is very similar to that of Jersey, where the very finest fruits are grown.

My too-short tour in Ireland was an extremely pleasant one, for I met with many—very many—kind friends, although I met them as a comparative stranger. Talk of freemasonry! why, the feeling of brotherhood amongst gardeners is far exceeding that of any other class. We find ourselves at home everywhere, yet nowhere have I found a welcome so warm as in the Sister Isle. Much—indeed I suspect a very great deal—of this overflowing kindness I owe to the high respect in which my introducer, Mr. James Robertson, of Dublin, is held. I owe to this gentleman many thanks for his valuable assistance in enabling me to see so much of his adopted country.

My tour was confined to the gardens around Dublin, in the counties Wicklow, Kildare, &c., and from that northwards to Enniskillen and Belfast. I will furnish your readers with more detailed notes on the more remarkable of the places I visited;

and I add as my opinion, that if in Ireland there are not so many fine gardens as in England, yet they will bear comparison with advantage in many respects.—B.

GROUND LEVELLING AND PRACTICAL GARDEN PLOTTING.—No. 3.

DRAWING PLANS.

HAVING given a short description of such materials as will be necessary for a beginner, I will proceed to apply them to their uses, commencing with fig. 6.

1. *To Bisect a Given Line.*—Draw the line *AB* (fig. 6). Use the compasses having a pencil leg. Put the steel point of the compasses in point *A*. Open the compasses until the distance is greater than the half of the line *AB*, and with the pencil describe the arc *dd*. Shift the steel point of the compasses to point *B*, and with the same radius draw the arc *cc*. The

Fig. 6.

Fig. 7.

points where the two lines cut each other, as in *d, c*, are perpendicular to or square with the line *AB*. Draw a line from the points of intersection—that is, from point *d, c*, to point *d, c*, and it will bisect or cut the line *AB*, into two equal parts, as at *m*.

2. *To Describe a Square on the Line AB.*—The line *AB* (fig. 7) is 1 inch in length, and represents 8 feet, being drawn to the scale of 8 feet to the inch. Erect a perpendicular line from point *B*, which is done in the following manner:—Take any two equal distances from point *B*, say the points *dd*; place the steel point of the compasses in point *d*; open the compasses until the radius is greater than *dd*; then with the pencil describe an arc, as in *c*. Shift the steel point of the compasses to the other point *d*; describe another arc, cutting the former one, as in *c*; draw the line *BC*, taking care it is as long as the line *AB*. Two sides of the square are now drawn, and *A* and *C* are centres. Place the steel end of the compasses in point *A*; open them until the pencil will just meet point *B*; and turn the compasses round and describe an arc, as in *D*. Then shift the steel point of the compasses to point *C*, and with the same radius describe another arc in *D*, cutting the former one; next draw the lines *CD*, and *DA*, and the square is formed. To prove the square, if the diagonal lines *AC*, and *BD*, are exactly equal in length, the square is perfect.

Fig. 8.

Fig. 9.

3. *To Describe a Circle.*—The diameter *AB*, being given—say 8 feet—find the half (4 feet); with the half as radius (*da*) describe the circle (fig. 8) with the compasses.

4. *To Form an Equilateral Triangle.*—The base line *AB* (fig. 9) is 8 feet. Find 8 feet on the scale. With the compasses from *A* and *B* describe two arcs, cutting each other in *c*. Draw a line from *A* to *c*, and from *c* to *B*, and the triangle is complete.

5. *To Construct an Oval on a Given Line.*—The line *AB* (fig. 10) is 8 feet in length. With half the line, *o*, as radius describe a circle. From *A* and *B* as centres draw arcs, with the radius *AB*, cutting each other in *E*. From *E* draw the line

E, c, c, which will bisect the line A B, in o, and also cut the circle in D. With D as a centre describe the arc ee, meeting the arcs drawn from A and B.

Fig. 10.

Fig. 11

6. To Describe an Elliptical Figure on any Given Line.—The diameter line A B (fig. 11) is 10 feet in length; divide it into four equal parts. From c and D, with the radius D A, or c B, describe circles touching each other in the centre. From c and D, with radius c D, describe arcs cutting each other in E F. Draw the lines E O, E D, F C, and F D, and produce them until they cut the circles in G, H, I, and J. From E and F, with the radius E G, or F J, draw arcs uniting G H, and I J, which will complete the figure.—M. O'DONNELL, Gardener to E. Leeming, Esq., Spring Grove, Richmond.

PEAS IN 1870.

The writer of the article on "Peas in 1870," which appeared in last week's issue of THE JOURNAL OF HORTICULTURE, is evidently incorrect in describing Carter's First Crop and Sutton's Ringleader as being two distinct sorts of Peas.

At the time of sending out this Pea, in 1864, it was discovered by the two firms who afterwards introduced it to the public, that they both were possessed of an early Pea of undoubted merit, but from the source whence it came, and also from its general appearance and characteristics, there was no doubt that the Pea, whether called Sutton's Ringleader or Carter's First Crop, was one and the same Pea. However, this is an old story now, because the Pea was at the time of sending out, and has been ever since, advertised by both firms as being identical; therefore Mr. Castle must either have been deceived by his seedsman, or have muddled his trials himself, as it is utterly incorrect that Sutton's Ringleader is 3½ feet high, or that it is either earlier or later than Carter's First Crop. It may be as well to remark that all early Peas are liable to degenerate in the quality of earliness, unless they are each year carefully selected; but even this fact will not assist Mr. Castle's statement, because we will challenge anyone to name an early Pea of 3½ feet high, which is earlier or so early as Carter's First Crop or Sutton's Ringleader. If you will permit us we will give you the results of our last year's trial of early Peas at our trial ground, the correctness of which we will vouch for:—

No.	Variety.	Sown.	In Bloom.	Fit to Pick.	Height.
1	Carter's First Crop or Sutton's Ringleader	March 5th	May 12th	June 6th	2 ft. 6 in.
2	Dickson's First and Best	"	" 15th	" 8th	3 ft.
3	Daniel O'Rourke	"	" 19th	" 13th	3 ft.
4	Early Emperor	"	" 22nd	" 16th	4 ft.
5	McLennan's Little Gem	"	" 1st	" 8th	1 ft.
6	American Fom Thumb.	"	" 22nd	" 13th	1 ft. 6 in.
7	Beck's Gem	"	" 22nd	" 16th	1 ft. 6 in.
8	Bishop's Long-podded	"	June 1st	" 19th	2 ft.
9	The Peabody	"	" 6th	" 24th	1 ft. 6 in.
10	Dwarf Waterloo Marrow	"	May 19th	" 19th	1 ft. 6 in.
11	Laxton's Supreme	"	" 29th	" 21st	4 ft.
12	Advancer	"	June 1st	" 19th	3 ft.

If it is of sufficient interest to your readers we could publish a complete list of our Pea trials. [Do; we will find space for them.—Eps.]

We may also remark that Laxton's Prolific Longpod Pea is not deserving of being described as "the worst-flavoured Pea of the season." It is one of the most productive of our Green Marrows, and in flavour is quite equal to any Green Marrow in cultivation.

While on the subject of Peas, we must confess our surprise that none of your numerous readers have had a word to say in favour of Laxton's Alpha. In our opinion it is a Pea without an equal amongst early wrinkled Marrows, both for its earliness and fine flavour.

We can recommend "E. G.'s" trial of Peas, which appeared in the Journal of the 19th ult., to Mr. Castle's notice, as a model of systematic correctness.—JAMES CARTER & Co., High Holborn.

Mr. CASTLE tells us, to grow Peas well the ground should be trenched 3 feet deep; permit me to inform him that all gardeners are aware of the fact, if they could only persuade their employers to give them the necessary labour. Secondly, Mr. Castle never sows Peas until March; he finds they come in as early as those sown in November. That does not agree with my experience. My Peas, sown on the 16th of November, were gathered last season on the 6th of June, Mr. Castle's on the 18th of the same month. Mr. Castle never sows Peas in November; he finds the birds and mice make great havoc among them. Let him procure six pennyworth of phosphorus paste, spread it on bread, use it three times during the winter, and the mice will not trouble him; and for the sparrows, a few strings of red worsted strung along the rows is all that is required.

Mr. Castle tells us that the last dishes were gathered on the 30th of September, but I sent to table a very nice dish this day (October 27th), but it will not be the last. I hope to go on gathering well into November; and this is nothing new, I have gathered Peas repeatedly on Lord Mayor's day.—R. GILBERT, Burgley, Stamford.

CLIMBING FERNS.—No. 2.

ODONTOSORIA.

The plants in this genus are usually associated with Davallia. I, however, entirely conform to the opinions of those authorities who assert their distinctiveness. The species introduced here is a most elegant plant for training along a rafter or pillar, where its light green airy fronds produce an effect equalled by no other Fern. It should be potted in a soil consisting almost wholly of peat and sand, with perhaps a small portion of loam added to it, and should be kept in the temperature of the stove.

O. ACULEATA.—This lovely Fern may be found in many gardens, sometimes under the name of Davallia aculeata, at others under that of Adiantum aculeatum, and yet how seldom are its beauties displayed to advantage! It is a scandent plant, and therefore requires more room than is usually accorded it. The fronds are bi-tri-pinnate, bearing cuneate somewhat lobed pinnae, which are bright light green. The sori are situated at the edges, with a somewhat pitcher-shaped indusium. The rachis is furnished with short slightly recurved spines. I consider this one of the most beautiful Ferns in cultivation. It is a native of Jamaica, and perhaps other places in the West Indies.

SALPICHLENA.

I am only acquainted with one species in this genus, and it stands in the opposite extreme to the plant just noticed. It is a bold-growing Fern; its fronds are bi-pinnate, extending indefinitely, and produce pinnae often 2 feet in length. Salpichlena is nearly allied to Lomaria; it has forked veins, which are all joined by a vein at the margin, and the sori are borne on a transverse vein running parallel with and close to the costa; the indusium is rolled over the sori like a tube. This plant enjoys a high temperature, and should be potted in peat and loam in equal proportions, with plenty of sand.

S. VOLUBLE.—In a situation where a large bold-growing Fern is desirable this will form a striking object. The fronds attain an immense length, and its long, dark green, arching pinnae are very effective, but it can scarcely be recommended for ferneries of limited extent. S. voluble is frequently to be found in Fern collections in a starved state under the name of Blechnum scandens. It is a native of South America.

GLEICHENIA.

This genus I always look upon as the aristocracy of the Fern tribe. The species are extremely elegant, and have a character peculiarly their own. There are two sets of this genus, one having small orbicular segments to the pinnae, and the other larger and broader fronds with linear pinnae, and the habit is less scandent. The latter section is by some authors considered sufficiently distinct to be elevated to generic rank under the

name of *Martensia*. The true *Gleichenias*, as before remarked, have a character peculiarly their own. Their fronds are several times dichotomously divided, extend almost indefinitely, and bear long narrow pinnae with oval or orbicular segments, which have somewhat the appearance of rows of beads. These plants are considered difficult to cultivate, and there is much truth in this opinion. They are somewhat hard to manage—that is to say, for any length of time. They are admirably adapted for cool ferneries; and I am convinced one of the chief causes of failure in the cultivation of *Gleichenias* is an excessive amount of heat. Another fault lies, I think, in confining them in too narrow a compass, for these plants are essentially surface-rooters; they do not want much depth, but they require an extensive surface for their rhizomes and roots to spread over, and if this accommodation is not afforded them the fronds become very weak through overcrowding, and dwindle away to miserable, sickly, sticky-looking objects. To cultivate these plants successfully I adopt shallow pots, and drain them well. The soil in which the *Gleichenias* thrive well with me is brown fibrous peat used somewhat rough. I add a good portion of silver sand, some lumps of sandstone, and a little light loam. They require a liberal supply of water all the year round, but especially during summer, at which season the sun's rays must be kept from them: in fact, I have found them succeed best in a house with a northern aspect.

G. MICROPHYLLA is a fine, free-growing, scandent plant, fit either for public exhibition or home decoration; in the latter case it may be either trained out upon sticks or upon a rafter or pillar. The fronds are several times dichotomously forked; the stems are all clothed with short reddish brown hairs; the ovate segments are dark green on the upper side, the under side paler and quite plain. It is a superb plant, and may sometimes be found in cultivation under the name of *G. circinata*, by which some authorities say it should be known. Native of Tasmania and various parts of New South Wales.

G. DICARPA.—In general habit this resembles the preceding; it has the same scandent fronds and bead-like pinnae. This, however, differs in the orbicular segments having the edges turned over, forming a little pouch or pocket on the under side. Another point of distinction is its perfectly smooth stems and branches, and it is somewhat more compact than *G. microphylla*. It is found in the same habitats as the preceding.

G. HECISTOPHYLLA.—In this species we have a very elegant plant, and perhaps the most slender-growing of all the scandent *Gleichenias* in cultivation. The dichotomous forking of the fronds is the same. The stems are all thickly clothed with reddish hairs; and the somewhat large orbicular segments have their edges rolled over and form a very small pouch on the under side. It is a native of New Zealand.

G. SEMIVESTITA.—An exception must be made in the cultivation of this species, for it really thrives best in the temperature of the stove. Its general appearance is the same as that of all the species in this section. The stems are somewhat densely clothed with reddish brown hairs; the segments inclined to be ovate and quite plain on the under side. Native of New Caledonia.

G. SPELUNCÆ.—This is one of the most beautiful kinds in cultivation. The fronds are forked, and the segments of the pinnae are somewhat larger than those of the species previously described, and not sacculate, bright light green on the upper side, very glaucous underneath. It should be grown in the cool house, and is a native of Tasmania and New South Wales.—
EXPERTO CREDE.

APPLE-GRAFT STOCKS.

THE Burr Knot Apple is described in "The Orchardist" by Mr. Scott, of the Merriott Nurseries, in Somerset, as striking freely from cuttings. The use of the Burr Knot as an Apple stock is very likely, whether under the guise of English Paradise I cannot conjecture, further than Mr. Scott, in his preface to "The Orchardist," says, or suggests it to be so.

I remember a story of an orchard farmer who, happening to push a random cutting of Burr Knot into the ground, and finding it strike wonderfully and fruit precociously, ever afterwards adopted it for Apple stocks, and which stocks he raised by thrusting cuttings of the Burr Knot into whole Potatoes, and planting the Potato and cutting, like a drumstick reversed, together, the Potato to rot, the cutting to grow. Perhaps the succulence of the Potato promoted the growth of the cutting.

The Stibbert Apple, too, is described by Mr. Scott, though not identified with the Dutch Codlin, if the same Apple. I

know not if the Stibbert stock is made use of under the guise also of English Paradise, further than Mr. Scott says as much in the preface of "The Orchardist."

The Nonesuch Apple is not mentioned as one of the English Paradise stocks in the preface already referred to, unless included as a surface-rooting Crab (Apple) stock, though Mr. Scott does not speak of the Nonesuch stock in very flattering words in his late reply in your Journal to my own inquiries.

Perhaps Mr. Scott will tell us if the various stocks used—Burr Knot, Stibbert, Nonesuch, Donein or Crab, and Pommier de Paradis, give any peculiar character to the foliage and hue of the bark of the Apple grafts or scions grown upon such stocks respectively, and how far the fruit of the graft or scion is affected by its foster-parent stock.—READER.

MUSHROOM-GROWING IN PARIS

THE readers of this Journal may have seen, in some of the daily papers, a description of a mode by which Mushrooms are said to be obtained with greater ease than by that usually adopted. This mode has its origin amongst our neighbours the French, and consists of sowing the spores or seeds of the Mushrooms instead of using spawn. This is all the essential difference there is; but some scientific means are necessary to obtain this seed, and the ordinary reader who may have perused the description of the manner in which the operation is performed, will be puzzled by the technical terms used, and in adopting the method in question it is probable he will be disappointed in the result. I certainly do not deny that Mushrooms may be so grown, but as many conditions are necessary for their successful cultivation, the mere fact of one particular method having once succeeded is no proof that it will always do so. Some condition necessary to success may be wanting, and a failure result, but those anxious to try experiments might do so in this case with perfect propriety, and, if successful, by reporting the result they would advance the science of horticulture.

The mode seems pretty well explained. A substance favourable to the growth of the Mushroom is prepared, and on this the seed (as I may be allowed to call it) is sown, and in process of time a crop is produced. This is the plain homely feature of the case, and if some one produce a specimen of Mushrooms so grown at one of the winter meetings of the Royal Horticultural Society, more light will be thrown on the matter. The Mushroom, in common with other Fungi, produces myriads of the most minute objects, which, whether we designate them as seeds or by any other name, evidently serve the purpose of reproduction, and they are in such abundance that they exist almost everywhere, but only grow in favourable situations. In the growth of Mushrooms by the mode described, I should say the conditions necessary to insure success must be correct to the greatest nicety, otherwise failure must occur. This often happens in the old-fashioned method of growing Mushrooms from spawn; and how uncertain, then, must be the result in the new one with such minute things as the seeds, to discern which a microscope is required.

In making the above remarks on the French mode of growing Mushrooms, I by no means intend throwing any discredit on the plan, or to damp the ardour of those intending to try it; on the contrary, I shall be glad to hear of its being extensively tried and the results reported. The fructification of most of our Fungi is but imperfectly known except to the learned few, and this class are not always expert cultivators, but we must listen to what they may reveal, and act accordingly. With such very minute objects as the seeds referred to, it is, I fear, hopeless to attempt much beyond carrying out an experiment or two. We must, therefore, wait and learn what nature can do for us, and in general she performs what would baffle the skill of our most expert nursery propagators. We see Ferns and Lycopods springing up in hothouses and other places favourable to their growth with such rapidity that every place is speedily covered with them, and when we become better acquainted with the requirements of the Mushroom, it is likely it may be obtained in as great an abundance.

Taking, therefore, for granted that what may be called the seeds of the Mushroom (not the spawn) are produced in such infinite numbers as to be everywhere at the season most suitable to the growth of Mushrooms, we may fairly expect these to be produced when all the necessary conditions are complied with. It is, therefore, not unlikely that in the caves at Paris, where Mushrooms are grown in greater abundance than per-

haps anywhere else, the conditions necessary to success are much more perfect than in most other places; and Mushrooms having been grown there so long, it is not unlikely the very atmosphere may be so charged with the minute bodies which serve to propagate this fungus, that Mushrooms may spring from them in course of time in the same way as Ferns and Lycopods are produced, when in a suitable position, without other aid from us than supplying the shade and moisture which are necessary to their growth. I am, therefore, not altogether a disbeliever in the possibility of Mushrooms being produced by seed as described in the daily papers, but I more than doubt the cultivator's having the means of sowing such seeds over his beds when prepared, and I would advise inexperienced readers to consult their seed catalogues carefully before they send for a packet of Mushroom seed, unless to confer a favour on some acquaintance the day after the 31st of March. It is not at all unlikely that the humorous Frenchman may have sown his beds with something that might resemble seeds in the presence of some special correspondent, and that Mushrooms followed; but I strongly suspect sand, dust, or something of the kind, formed the seeds seen by the gentleman of letters, ordinary spawn having been used before. It is not at all unlikely that the spawn in one bed may have run along the floor and reached the other, and thus produced a crop, or the very air may be so loaded with all the requirements necessary to this end that only subjects to work upon may be wanted, and fresh dung furnishing this, success is the result. At the same time it is most likely that when tourists, visitors, and specials were not in the caves, pieces of spawn were inserted in the beds and that these did the work and not the mysterious Mushroom seeds. More need hardly be said on the matter, than that the caves spoken of must be well adapted to the purpose, and great credit is due to those who there cultivate the Mushroom so successfully.—J. ROBINSON.

Since the above was written what a sad change has come over the fair and beautiful city of Paris! Its gardens, parks, squares, and even cemeteries, are converted into so many enclosures for cattle, or torn up for still ruder purposes, while the Mushroom caves may be turned to purposes widely different from that to which they were put when the above was penned. All must mourn that such a change should take place. At some future time I may return to the subject of growing Mushrooms in caves, for it is not without its parallel in this country, as very many years ago excellent specimens of Mushrooms were produced in a coal mine where horses were kept, and Mushroom beds in chalk caves are not uncommon.—J. R.

AUTUMN PLANTING OF POTATOES.

The experiment was tried upon the farm of Mr. William Lawson, at Bleunerhasset, Cumberland. The sets were Regents, chiefly whole, and varying from 3¼ to 1¼ oz. in weight, 1¼ being the average, and were planted about 9 inches apart. They were sorted from one field's produce, and of a uniform size, to ensure equality of conditions. The plots, of three drills each, were first before planting sown with a mixture consisting of superphosphate (mineral), 5 cwt.; marlate of potash, 2½ cwt.; and sulphate of ammonia, 1¼ cwt. per acre. The March plot was first to turn yellow, then February, April, and all except May came next, May being the last. All were raised, sorted, and weighed October 6th, with the following results:—

AUTUMN versus SPRING PLANTING.

Date when planted.	Weather at time of planting.	Weight per Acre.	Value per cwt. as raised.	Value per Acre.
1869.		tons. cwt.	Shillings.	£ s. d.
October 6	Mild and dry.	3 11	2 31	8 4 1
November 5	Cold winds and heavy showers.	5 14	2 30	11 13 5
December 15	Cold and slight rains.	5 3½	2 55	13 17 9
1870.				
January 12	Cold and damp.	6 6½	2 54	16 0 7
February 7	Frost and slight snow.	9 5	2 46	22 15 8
March 7	Dry frost.	9 10½	2 49	22 15 7
April 8	Warm.	8 8	2 49	29 3 2
May 9	Warm.	9 14	2 42	21 18 9

In January plot, the misses were very numerous; April sets were much sprouted when planted; in May the seed left was insufficient, and this plot was planted with a mixed lot, containing Rocks; it cannot, therefore, be fairly compared with the others. The column "Value per cwt. as raised" is calculated from the weights of large, medium, and small, when hand-

picked; the large being valued at 4½d. per stone, the medium at 3d., and small or pig Potatoes at 2d. They are such as would be sorted by 1¼ and 1½ inch riddles. Excluding October and November, and also M.v. because of its mixed seed, it will be seen that the best quality—i.e., the highest value per hundred-weight, was produced by the seed longest in the land. Thus February, though 5 cwt. less per acre in weight than March, is of almost equal money value per acre, because of its greater proportion of large Potatoes, and, consequently, higher value per hundredweight. As far as this one experiment goes, it shows:—1st, That for weight early in March is the best time to plant. 2nd, That for profit February is equally as good as March.—(Mark Lane Express.)

LILIUM AURATUM AND OTHER BULBOUS PLANTS.

I HAVE read with much interest Mr. Douglas's note on the cultivation of *Lilium auratum*. Will he tell us, in addition, why he considers it best to shake the soil entirely from the roots in preference to scratching away the loose soil? I should be very sorry to treat mine in the way he recommends. In 1869 mine threw up one stem and produced fourteen blooms; this year it threw up two stems, which produced seventy-six blooms.

If Mr. Douglas dries-off his *Hyacinths*, *Tulips*, and other bulbs, I would advise him another summer to water them if necessary as long as there remains a leaf, and report the results.—EXPERTO CREDE.

[In the article on *Lilium auratum* referred to, allusion was made more particularly to pots containing a number of bulbs. I said, "As many as a dozen bulbs are planted in a 13 inch pot." As the result of my cultivation is given, "EXPERTO CREDE" will observe that three bulbs in 1869 produced fourteen spikes. In 1870 all, or at least all except two pots of bulbs, were repotted about the middle of October, and on shaking out the bulbs from the pot alluded to above there were fourteen fine bulbs, the produce of last year's three bulbs. These were separated carefully and repotted in a 15-inch pot. As there is no room for them in the frames this year, I have plunged about two dozen pots of them in cocoa-nut fibre refuse out of doors. They had a good drenching of rain before they were plunged, and more since, which will do them no harm. By-and-by, if severe frosts set in, something will be placed over them to throw off the water. They will be plunged in the frame in January. If fourteen good bulbs were obtained from three in one season, surely the system of cultivation must be good, especially as they throw up good strong spikes which flower well. Several of the spikes were 10 feet in height.

I have frequently done as "EXPERTO CREDE" seems to have done with his one bulb in a pot—that is, only scratched away a little of the earth and repotted in a larger-sized pot. Thus treated the bulbs have done well, but when three or four spikes are thrown up from one bulb, I separate the bulbs and they also do well; you can then have three or four pots, or you can plant all in one pot.

One thing must be borne in mind—do not disturb *Liliums* after they have started into growth; they do so very soon after the spikes die down. I had some *Lilium lancifolium album* bulbs which, although standing out of doors all the season except the few weeks when they were in flower, had started into growth by the middle of October, when the others were potted; and, further, if you want your work well done, do it carefully, do it at the right time, and do it yourself. The right time to pot *Liliums* is when the leaves turn yellow on the stems.—J. DOUGLAS.]

BOX EDGING.

Your correspondent, Mr. O'Donnell, says (page 301), "As soon as all the Box is planted, the whole should be clipped to an equal height, and flat at the top." I presume he must mean the time of planting to be the month of April, which would be carrying on improvements to a very late period, if the young gardener wish to keep himself equal to all the demands of an establishment. Surely he could plant at the end of September or October, but between this time and April I think cutting Box very dangerous. Should there be a severe winter the major part of it would be killed, and to replace it after the work is finished in small designs is a job better dreamt of than performed.

As to cutting Box flat, that is entirely a matter of taste, but

to me it is very unsightly, cramped, and too formal, with the great disadvantage of harbouring myriads of insects. In some small chain patterns I have seen clumps of Box cut flat, and in different shapes, but when these are compared with the free lightness of the plants in the beds they are anything but in harmony with the latter, however well they may look when the beds are empty: therefore I think they are at all times to be avoided. I think that all edgings should be as light as possible, and Box is certainly one of the lightest if cut in the shape of an inverted V at 2 inches in height, but if it is cut square, 4 inches by 4, as it often is, it looks very heavy indeed.—J. T.

ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 2ND.

FOR this dull time of year the Council-room looked unusually gay; Orchids were represented by some splendid specimens from Lord Lonsborough's and Messrs. Veitch's: Chrysanthemums, though the meeting was early for them, formed a most effective mass, while of fruits there was an excellent display. The attendance of visitors was large, and it is to be regretted that many of them availed themselves of the time when others were seated at the General Meeting to move about the room, to the great inconvenience of those who were bent on hearing.

FRUIT COMMITTEE.—G. F. Wilson, Esq., F.R.S., in the chair. A prize of £5 was offered by Messrs. J. & C. Lee, of Hammersmith, for the best three bunches of Madresfield Court Grape. Three very fine bunches were exhibited by Mr. Zadok Stevens, of Trentham, and three by Mr. Adams, of Bank Hall, Barnley. Those of Mr. Stevens, being infinitely the best, received the prize. The berries were very large and deliciously flavoured. Mr. J. Tomkin, gardener to S. T. Kekewich, Esq., Peamore, sent a large bunch of a Grape to be named, which proved to be Alicante. Mr. W. Ellis, gardener to R. Lewis, Esq., Greenford Hall, Middlesex, sent three bunches of Black Prince Grapes, from Vines that had been severely infested with mildew. They were cut back and lifted, and these were part of the produce of sixty bunches from two rods. Mr. Wells, of Southend, sent eight bunches of Black Hamburg, grown in the ground vineries, which were of such superior quality as to obtain a special certificate. He also exhibited bunches of the Sultan Grape without seeds. A shoot of a Hungarian Grape, introduced by Rev. M. J. Berkeley, and grown at Chiswick, was exhibited to show the very brilliant hues of dying foliage. It is the richest-coloured of all the varieties. Mr. Challis, The Gardens, Wilton House, sent a Pine introduced from India, which had somewhat of the character of the Blood and Otaheite, but the flavour was not remarkable. Messrs. J. & C. Lee sent fruit of the Autumn Surprise White Raspberry. Mr. Lamb, gardener to G. T. Davy, Esq., Colston Bassett, Bingham, sent a Melon, weighing about 3 ozs., called Colston Bassett. It is a handsome-looking fruit, lemon-coloured, and finely and evenly netted, but the season was too late to form a correct judgment of its merits.

Mr. Charles Turner, of Slough, sent dishes of handsome fruit of Cox's Orange Pippin. Mr. Small, of Colnbrook, sent a seedling Apple, called Queen Victoria, too much like Golden Noble. Mr. Jennings, of Shipston-on-Stour, sent fruit of his new Apple, The Fairy, figured in "The Florist," of March last; the season being early the flavour was as yet acid. Mr. Alexander Dean, Old Shirley, Southampton, sent an Apple, presumed to be a seedling from Blenheim Pippin, called Beauty of Haunts. It was the same as Blenheim in texture and flavour, but the colour was higher than that of the Blenheim usually is, some specimens being quite red on one side. The Committee considered it the same as Blenheim. P. Northall Laurie, Esq., of Paxhall Park, Hayward's Heath, sent six dishes of Apples grown on cordon trees, consisting of Reinette de France, Reinette du Canada, Calville Blanche, Golden Winter Pearmain (called Reine des Reinettes), and Reinette d'Angleterre (King of the Pippins). The Calville Blanche and Reinette du Canada were unusually fine, and received a special certificate. Mr. McKenzie, Alexandra Park, also sent eight dishes of Apples which had been grown on cordons, which received a special certificate. Mr. Gardiner, gardener, of Eastington Park, Stratford-on-Avon, sent thirty-nine varieties of Apples, which received a special certificate. Mr. Davie, Broad Bridge Street, Peterborough, sent two seedling Apples, one of which was recognised as Rymer. G. F. Wilson, Esq., Weybridge Heath, sent a dish of very handsome Beurré d'Anjou Pears.

Messrs. Veitch & Sons sent specimens of their Giant Autumn Cauliflower, a fine, large, late Cauliflower. The seed was sown on the 16th April, the same day as Walksheren, Asiatic, and Early Erfurt. This is now coming into use, while all the other sorts are quite past. Mr. Lamb, gardener to G. T. Davy, Esq., Colston Bassett, sent tubers of a Potato from Guatemala. Mr. C. Hales, Manor House, Bassingbourne, sent a large kidney Potato, which when cooked was mealy and of good flavour. Mr. Gunn, The Furze, Lee, Kent, sent some very large Tomatoes, which were coarse and considered objectionable. Mr. Gilbert, The Gardens, Buryholy, sent a seedling Cucumber called Knight of St. Patrick, raised between Telegraph and Wonderful.

Mr. B. Saunders, of St. Helier's, Jersey, sent a collection of twelve dishes of Apples and twelve of Pears, all of which were remarkably

well grown, and received a special certificate. Messrs. Carter & Co., of Holborn, sent a collection of twelve varieties of Celery, and examples of Red Flourball Potato, a very large red-skinned variety. Mr. Lidgard, of Hammersmith, sent specimens of Williams's New White Matchless Celery.

Prizes were offered for the best six dishes of dessert Pears, and brought from fifteen competitors many dishes of fine fruit. The first prize was awarded to Mr. Stephenson, gardener to F. C. Barker, Esq., Leigh Hall, Essex, who had Duchesse d'Angoulême, very large and fine; Beurré Diel, Marie Louise, Knight's Monarch, Glou Morycan, and Passe Calmar. Mr. Miles, gardener to Lord Carrington, Wycombe Abbey, was second, with very fine fruit of Beurré Diel, Huysse's Victoria, Beurré Bose, Van Mons Léon le Clerc, Marie Louise, and Beurré Clairgean. The third prize went to Mr. S. Ford, gardener to W. G. Hubbard, Esq., Horsham, for Forelle or Tront Pear, very fine; Duchesse d'Angoulême, Triomphe de Jodoigne, Nouveau Poiteau, Beurré Diel, and Thompson's.

Prizes were likewise offered for the best collection of Potatoes, and there were only two competitors. The first prize was adjudged to Mr. Frisby, gardener to H. Chaplin, Esq., Blankley Hall, Sleaford, who had tubers of very large size, several of them, however, being very coarse kinds. Among the varieties were American Peach Blow, Pink-eyed Regent, Ashleaf, Myatt's Prolific Ashleaf, Rivers's Royal Ashleaf, and Lapstone. The second prize went to Mr. S. Ford, who had generally clean, and for the most part rather small tubers.

FLORAL COMMITTEE.—W. Beattie Booth, Esq., in the chair. Mr. Denning, gardener to Lord Lonsborough, Grimston Park, Tadcaster, sent a splendid collection of Orchids, most conspicuous among which was a magnificent specimen of *Vanda carnlea*, with four spikes, each with from thirteen to fifteen flowers; *Cattleya Harrisoni* and *Oncidium aurosum* were also remarkably fine. Among the others were the beautiful *Pleione Wallichii* and *lagenaria*, *Phalenopsis Lowii*, *Vanda lutescens*, *Cattleya maxima*, very fine, the brilliant scarlet *Sophranitis grandiflora*, *Odontoglossums*, *Oncidium*, *Miltonia Morelliana*, the large-flowered white and orange *Dendrobium formosum*, &c. Mr. E. Culley, gardener to E. Salt, Esq., sent a pale variety of *Odontoglossum Alexandræ*, with a very fine spike.

Messrs. Veitch contributed a collection, in which were a fine specimen of *Cattleya labiata*, *Miltonia Warszewiczii*, an excellent example of *Zygopetalum maxillare*, *Apelandra aurantiaca* Roezlii, of which the orange scarlet flowers are very showy, *Urecolina aurea* with pendulous yellow bells, *Adiantum Veitchii*, *Dracena porphyrophylla*, a noble looking plant, and several *Cattleyas*, the most remarkable of which was *C. Dominian lutea*.

Mr. Bull, gardener to J. Montgomery, Esq., Pole Hill Lodge, Hillingdon, sent a nice collection of *Cyclamens*; and Mr. C. Edmonds, Hayes Nursery, sent a similar but larger collection in excellent bloom, likewise several seedling *Tricolor Pelargoniums*. Mr. R. Clarke, market gardener, Twickenham, also had a large collection of *Cyclamens*.

From Mr. Bull, of Chelsea, came a group of Palms, Cycads, Orchids, and other plants. Of the first named *Licuala horrida*, a pleasing light green sort, received a first-class certificate; and among the others were *Welfia regia*, *Zalacca Wagneri*, *Astrocaryum mexicanum*, *Areca Verschaffeltii*, *Damocorops melanochates*, and *Cocos Romanzoffiana*. A very handsome species of *Enecephalartos*, which Mr. Bull has before exhibited, also formed part of the collection. *Curculigo recurvata striata*, with handsome white-striped leaves, received a first-class certificate. The Orchids consisted chiefly of *Odontoglossum grande*, *Vanda carnlea*, *Pleione lagenaria*, *Burlingtonia venusta*, and *Oncidium Papilio* and *crispum*.

Mr. Parker, Exotic Nursery, Tooting, sent *Ixora amabilis*, which has before received a certificate. *Begonia Craigii*, with dark bronzed foliage and of strong growth, a handsome plant for mixing with others with lighter-coloured foliage, came from Major Trevor Clarke; and *Begonia geranioides*, with pure white flowers, and leaves not unlike those of a Geranium, of dwarf growth and very free-flowering, was exhibited by Messrs. Backhouse, of York. Messrs. Perkins & Sons, Park Nursery, Coventry, sent *Gazania splendens arceo-variegata*, the leaves irregularly edged with yellow, but rough in appearance.

Mr. Morris, Kent Waterworks, Deptford, showed a basketful of seedling *Tricolor Pelargoniums*, and specimen plants of Lucy Grieve and Mabel Morris. King of Trumps, with large trusses of bright orange scarlet flowers, was sent by Mr. Eckford. From Messrs. A. Henderson & Co. came *Ficus vesca variegata*, the leaves variously marked with greenish white, the variegation sometimes covering nearly one-half of the leaf. Messrs. E. G. Henderson & Son sent a large group of *Tricolor Pelargoniums*; *Bouvardia elegans*, stated to be an improvement on *Bouvardia Hogarth*; *Mohria thurifraga achilleefolia*, a very elegant crisp Fern, which had a first-class certificate; and a fine collection of winter-flowering tree Carnations, of which Vulcan, red, received a first class certificate. From the same firm came also several seedling Japanese Chrysanthemums. First-class certificates were awarded for Bismark, very showy, orange, and Erectum superbum, fine violet rose. Mr. Bull likewise sent several varieties, of which Jane Salter received a first-class certificate; it is a white tinged with purplish lilac, 7 inches in diameter, and is a highly decorative variety. Garnet, rich blood red, was very fine in colour, though comparatively small. Renown, large-flowered, with broad incurved florists, yellow tinged with brown on the back, received a similar award. Mr. William

Paul exhibited cut blooms of seedling hedding Geraniums, many of them new in colour and very beautiful.

A first-class certificate was given to Messrs. Cathash, of Highgate, for *Acubia japonica* f. *aureo-maculata* with the leaves much more extensively variegated with yellow than the common kind. From the Society's garden at Chiswick was sent a plant of *Dahlia imperialis* about 9 feet high, and bearing a few flowers and a profusion of buds. Mrs. McIntosh, 25, Norfolk Terrace, Bayswater, sent a case of beautifully skeletonised leaves by a process which is stated to be very simple, and to occupy only an hour. For this a commendation was given.

First-class certificates were given to Mr. Bull for *Zalacca Wagneri*, *Corcaligo recurvata striata*, *Licuala horrida*, and Japanese *Chrysanthemums* *Jane Salter* and *Renou*; to Messrs. E. G. Henderson for *Mobria tharifragu achilleæfolia*, winter-flowering tree *Carnation Vulcan*, and for Japanese *Chrysanthemums* *Bismark* and *Erectum superbum*; to Messrs. Veitch for *Dracena porphyrophylla* and *Cattleya Dominiana lutea*, and to Messrs. Cathash for *Acubia japonica* f. *aureo-maculata*.

A second-class certificate was awarded to Mr. Eckford for *Zonal Pelargonium King of Tramps*.

Special certificates were given to Messrs. Veitch for the group of plants, and for *Zygotelum maxillare*; to Mr. Denning for his collection, also for *Cattleya maxima*, *Cattleya Harrisoni*, *Phalaenopsis Lowii*, and *Vanda cœrulea*; to Mr. Bull for his collection; to Mr. H. Clarke, Mr. Edmonds, and Mr. Bull, of Hillingdon, for collections of *Cyclamens*; to Messrs. E. G. Henderson for a group of tree *Carnations*, and to Mr. Morris for *Tricolor Pelargoniums*.

Prizes were offered on this occasion for specimen plants and cut blooms of *Carnations*, also for berried plants.

Class 1 was for the best six large-flowered *Chrysanthemums*. The first prize was taken by Mr. Rowe, gardener to Mrs. Lewis, Rotherhampton, with remarkably fine specimens, in full bloom, of *Lady Harding*, *Prince of Wales*, *Maréchal Ducroc*, *Dr Sharpe*, *splendid*, *Mrs. George*, and *Lady Talfourd*. The second prize went to Mr. James, gardener to W. F. Watson, Esq., Isleworth, who had *Mrs. George Rundle* in good bloom, *Prince Alfred*, with *Queen of England*, *Golden Queen*, and others not fully out. Mr. Forsyth, of Stoke Newington, was third with specimens of excellent growth, and which will be very fine a week or two hence.

Class 2 was for six *Pompons*. Mr. Rowe was again first with, among others, very fine plants of *White* and *Golden Cedo Nulli*, and several *Anemone*-flowered kinds. The second prize went to Mr. James, gardener to W. F. Watson, Esq., whose plants, though well grown, were not in full bloom.

Class 3 was for twenty-four cut blooms. In this Mr. Rowe took the first prize with an excellent collection, in which were very fine examples of *Empress of India*, *Rev. J. Dix*, *Princess of Wales*, *White Globe*, *Prince Alfred*, *Novelty*, *Queen of England*, *Venus*, *Jardin des Plantes*, *Lady Slade*, and *Lady Talfourd*. Mr. Forsyth came second with a stand in which were fine blooms of several of the above.

Class 4 was for the best twelve. In this Mr. Rowe was again first, and Mr. Berry was second, Mr. James being third.

Mr. Forsyth exhibited excellent stands of *Anemone Pompons* and Japanese varieties.

Only one collection of berried plants in pots was exhibited, and it was far from equal to what might have been expected. It consisted of *Ardisia crenulata*, *Solanums*, *Capsicums*, and a *Berberis*. This came from Mr. George, gardener to Miss Nicholson, Patney Heath, and received a first prize.

GENERAL MEETING.—S. Rucker, Esq., F.L.S., in the chair. After the usual preliminary business had been gone through, in the absence of the Rev. M. J. Berkeley, who had been called away through the sudden illness of a relative, Major K. Trevor Clarke made a few remarks on the plants shown. There was, however, he said, a dearth of objects of scientific interest such as usually formed the subjects of comment at these meetings. He then pointed out one of the autumn *Crocuses*, *Crocus longiflorus*, as being not only very uncommon, but very pretty. In the pomological department he would direct especial attention to the *Fairy Apple*, which had sprung from the seed of the scarlet *Siberian Crab*, mentioned in our Fruit Committee report, and remarked that an enormous improvement is at once effected when wild species are fertilised with pollen of cultivated garden kinds.

Mr. Marshall directed attention to the *Tree Carnations* as most useful plants for conservatory decoration in winter, on account of their continuous blooming; also, to Mr. Bull's patent cases for the transmission of plants across the tropics. These have spars of wood across the glass like Venetian blinds, which prevent the sun parboiling the contents of the case, and are also provided with ventilation at the top. To illustrate the effects of the ordinary plant cases on *Orchids*, Mr. Bull sent a large basketful utterly destroyed in transit. Messrs. E. G. Henderson likewise sent a case, the principal feature of which is, that the drip from the front of the glass runs into a zinc spout, and is conveyed into a perforated tube surrounded with charcoal at the bottom of the case, whence the moisture passes through the soil or packing before again entering the atmosphere of the case. The front is padded on, then fastened with screws. This case, which we believe has been found to answer well, is a lean-to form, Mr. Bull's, as shown, being a span-roof.

The Chairman, in announcing that the next meeting would be held

on December 7th, said that Mr. Bateman had offered a £5 prize for *Cattleyas*, further particulars respecting which would shortly be published.

HOW TO OBTAIN ROSES ON THEIR OWN ROOTS.

I HAVE read in a contemporary article under the heading of "Roses for Hedges." This is a good idea—one I, as an old Rose cultivator, have long believed in and practised. The month of November, into which we are just entering, is a busy time for me as a grower of Roses, as during that month I put in my cuttings, and plant Briar and Manetti stocks for budding. With regard to cuttings, it is of the greatest importance to get them all planted before severe frosts set in, and the ground gets too cold. Although both the Dog Rose and Manetti are hardy, they are apt to suffer from the effect of frost if exposed to it after they are taken up, and weak shoots, instead of strong healthy growth, result.

In any place where there is a great demand for cut Roses, every exertion should be made to keep up a sufficient supply. I always make it a rule here to supply the table with cut Roses during eight months out of the twelve: in March and April I get blooms from plants forced in pots; in May from walls; and from that time till the autumn has begun to strip the trees of their emerald tresses, the blooms come from various sources—some from plants budded on the Briar, some on the Manetti stock, and others from plants on their own roots. To obtain a good supply of Roses, three classes are principally grown—namely, *Noisettes*, which are mostly grown on walls, and protected with branches of evergreens during winter; *Tea Roses*, which are grown and protected the same way as the *Noisettes*—both of which I find to bloom earlier and finer from the protection they get, as the blooming wood is preserved intact, instead of being killed back, as is frequently the case; and the *Perpetuals*, which form the largest class grown here. A great many of these are on their own roots, and these I obtain in a very simple manner. I first trench a piece of ground in the kitchen garden, two spits deep, and mix plenty of rotten dung with the soil as the work proceeds. The cuttings I prepare in the following manner: I select the strongest growers of the *Perpetual* class, and cut up the wood into lengths of about 6 inches, and take out all the eyes but the three top ones. The ground should be trodden firm at planting time, and I always select for this a day dry enough to prevent the soil sticking to one's feet. A line is put across the ground, and the soil chopped away from the line by the spade just deep enough to take the cuttings, leaving the eyes out of the ground; they are placed from 4 to 6 inches apart, and the soil trodden firmly about them. And so I plant a piece of ground, leaving a space between the rows of fully 2 feet. I find the cuttings strike more readily in a sandy soil, and generally place some road-grit about them previously to treading the earth firmly against them. Here the cuttings remain for two years. At the end of the first year the growth of that season is cut back to about four or six buds from the ground, and by the end of the second year they form fine healthy plants.

These I use for the formation of *Rose hedges*, the front row of a *Rose border*, for potting, for forcing purposes, or to form a bed of *Roses* on their own roots. The ten varieties of *Perpetuals* now to be named are very fine plants from cuttings struck this way three years ago, and they are all strong growers and constant bloomers—viz., *Général Jacqueminot*, *John Hopper*, *Jules Margottin*, *Anna Alexieff*, *Duchesse d'Orléans*, *Auguste Mie*, *Anna des Diebach*, *Charles Lefebvre*, *Mademoiselle Louise Carique*, and *Madame Alfred de Rougemont*.

There are two hardy *Tea-scented* *Roses* growing with the above that stood the severe frost of last winter without any protection—namely, *Gloire de Dijon* and *L'Enfant Trouvé*, a beautiful yellow-flowering kind.

If I were to form a *Rose hedge* of one particular flower, it would be *Jules Margottin*, an old but very free-blooming *Rose*, that is a great favourite with me, and, I doubt not, many more.

—WILLIAM PLESTER, *Elsenham Hall Gardens*.—(*The Gardener*.)

LARGE PRODUCE FROM ONE POTATO.

HAVING obtained a fine *Bovina* *Potato* (weight 1 lb), I cut about two-thirds of it into fourteen sets, and planted them on the 23rd of March. As the rest of the *Potato* showed no eyes, I exposed it to a good bottom heat; by the 2nd of April it had

sent out five vigorous shoots. I then cut it into as many sets, and planted them, having previously manured the ground well, and covered it with an inch of sand. I took up the crop October 20 h, when I had a yield of 133 lbs; thirteen roots weighed together 11½ lbs., one of these weighed 13 lbs.; eleven Potatoes weighed 27 lbs., including one 4 lbs. weight. These Potatoes are most excellent for table use.—R. L. BRADSHAW, *Appleton Academy, near Warrington.*

PORTRAIT OF MR. RIVERS.

THE following extracts from letters enclosing subscriptions, will convey some idea of the motives which influence the contributors to the memorial:—

"I do not know Mr. Rivers personally, but I look on him as a great public benefactor."

"Rivers has given the world his brains, and well deserves recognition."

"I am glad to have this opportunity of showing my respect for one who has contributed more to my enjoyment of life, during the past ten years that I have been an invalid, than any other man living."

The following is the list of the subscriptions already received, towards carrying out the above object:—

SUBSOIL TEMPERATURES.

THE following is an extract from the report of the Under-ground Temperature Committee of the British Association.

At depths of 2 or 3 feet it is necessary to observe, once a week, or so, throughout a year, in order to get the mean temperature at that depth for that year; and this may differ by a considerable amount from the mean of a series of years.

In the report of the Scottish Meteorological Society for the quarter ending December, 1862, there is a comparison of the mean temperature of the air with that of the soil at the depths of 3, 12, and 22 inches, at four stations, from observations extending over five years; and in the "Journal" of the same Society for the quarter ending December, 1865, there is a comparison of the temperature of drained and undrained land from one year's observations, undertaken for this purpose at two stations, and including also a comparison with the temperature of the year. The mean temperature of the air for each day is, in these comparisons, assumed to be the simple arithmetical mean of the maximum and minimum, as indicated by self-registering thermometers 4 feet from the ground. From these observa-

tions, it appears that the mean annual temperature of the soil was in every case rather above that of the air, and that the excess was greater for sand than for undrained clay, and was greater for drained land than for the same land undrained.

The greatest excess occurred in the case of the 22 inch thermometer at Nookten (Valle of Leven), where both surface and subsoil are sandy and dry. The five yearly means at this station were:—

Air 46°.1; soil at 3 inches 46°.3, at 12 inches 47°.3, at 22 inches 48°.0; giving an excess of 1° 9 for the temperature at the depth of 22 inches as compared with air.

The smallest excess, in the case of the 22 inch thermometers, observed for five years, was at Linton (East Lothian) where it amounted to 0°.7; but the observations on the effect of drainage gave for the year of observation an excess of only 0°.2 at the depth of 30 inches in light sandy but undrained soil under a Ryegrass crop, at Otter House near Loch Fyne, the corresponding excess for drained land of the same kind and in the immediate vicinity being 0°.9.

The mean temperature at the depth of 3 feet at Professor Forbes' three stations at Edinburgh, from five years' observations, gave an excess of 0°.55 above the mean temperature of the air at Edinburgh as determined by Mr. Adie's observations.

Observations on soil temperature in England are much needed, but the Greenwich observations give an excess of soil above air temperature falling within the limits above quoted, the excess at 3 French feet being 1°.7, while at 24 French feet it is reduced to 1°. The soil of which the Observatory Hill is composed, and in which the thermometers are sunk, is dry gravel, and the unusual circumstance of decrease of temperature downward observed in the comparison of the 3-feet and 24-feet thermometers, seems to indicate that the surface of the hill is warmer than the surrounding land.

LABELS FOR FRUIT TREES.

"A. R." in last week's issue recommends zinc, and states that "if the label be suspended by copper or lead wire it will last for generations;" "that a glance will show whether the wire is cutting into the tree or not, and that a minute or two will rectify the matter." I once indulged the same delusive fancy, and suffer from it now. First I used lead wire—chemical action, I believe, takes place, besides the harder edge of the zinc cutting the softer lead wire—and about twelve months saw all my labels on the ground; next I used annealed copper wire on about a thousand trees. I am now busy cutting these labels off, for wire seems to have a prescriptive right to cut into the bark and fasten itself in every possible way without the least provocation, causing no end of gum and canker, and if by any remote chance, these do not occur, the label is the sport of winds and the ruin of the bark. I now use a strip of flat lead, stamped with the number which corresponds to the particular tree in my orchard book. This may be liable, besides the trouble, to as many evils as the methods I have already abandoned, but as yet I am innocent.

"A. R." well depicts the promiscuous misnaming of fruit trees. Nothing is more common than to find trees, and some of the commonest, wrongly named; and the lack of knowledge of varieties, and, in fact, of fruit-culture generally, is remarkable in many gardeners who excel in floriculture. As to correctly naming trees, the "greater nurserymen" are by no means immaculate. I have received many trees, from one of the best in every way, wrong to name; but when one has experienced the difficulty of keeping a few hundreds right in one's own garden, and then considers the thousands of each sort a nurseryman is expected to produce, the marvel is that they are so often correct.—C. C. E.

ARE GUELDRIS ROSE BERRIES POISONOUS?

WE ask this question because of the evidence given at an inquest held at Sudbury, Suffolk, on the 27th ult., on the body of the child of the Superintendent of the Cemetery, whose death was supposed to have been occasioned by eating the berries of the Gueldres Rose (*Viburnum Opulus*).

Mr. W. B. Smith, surgeon, deposed that he had made a post-mortem examination of the body, assisted by Dr. Williams. They could discover no natural cause of death; he inferred that death must have been caused by the absorption of the active principle of some narcotic poison. Dr. Taylor, in his work on toxicology, had stated that narcotic or vegetable, even

irritant or mineral poisons, could occasionally be taken and death be caused, yet no trace was left behind, nor any irritation. Generally, in the case of irritant poisons especially, there were traces; had there been any they must have seen them; they might be carried off by vomiting and purging. They found no traces of any poison whatever, nor anything to cause a natural death. The evidence was negative rather than positive. He inferred from this and the symptoms he observed during the child's illness, and from all the surrounding circumstances of the case, that death resulted from some narcotic poison.

Dr. Williams fully agreed with Mr. Smith's evidence, and said there was not very much known of the berries of the Gueldres Rose, and in toxicological works they were not said to be poison. But he had made experiments within the last few days, and was now able to state that these berries were poisonous if taken internally, but at present he could not say how long it would take for them to operate fatally after taken into the system.

Other evidence threw no light upon the subject, after which the Coroner summed up, and the jury returned a verdict "That deceased died of narcotic poison, but there is no evidence to show what that poison was or how it came into the system." Dr. Williams said he was conducting further experiments with relation to these berries, their properties, and their effects, &c.

BOUQUETS.

I advise that no bouquets of real flowers should be employed—one gets tired of the unvarying scents of Roses, Violets, and Heliotropes. I have a bouquet of artificial flowers so exquisitely made that they cannot be known from real flowers, and I put on them any perfume I like, and change the perfume whenever I please.—F. C. S.

["Tired of the scents of Roses, Violets, and Heliotropes!" If you ever become wearied with the sun's light, perhaps you will apply to the American tallow chandler who apologises to that luminary for having candles that are more brilliant. We will add a narrative, also from an American source.

TO BE PITIED.

I happened lately to be in the room with a semi-invalid, when a handful of choice flowers, the gift of a thoughtful neighbour, was brought in by her niece.

"See, aunt," said the young girl, "what a lovely bouquet Mrs. M— has sent you."

"Do you call that a bouquet? To my notion it is about big enough for a nosegay," was the querulous reply.

"Oh, yes, a nosegay; that is a better name, and it fully deserves it, for it is as fragrant as it is beautiful. Smell that Heliotrope, now."

"I don't think there is anything particularly beautiful in a Heliotrope; I call it a very plain flower, and then it wilts very quickly in water."

"Well, there's a Lady Washington—that will grow and blossom in water for days."

"Yes; but that ain't fragrant. I don't care much for flowers without fragrance."

"You love the Rose, then, the queen of the flowers," pursued the niece, who seemed determined to make her aunt say something pleasant. "That has beauty and fragrance, too."

"A very original remark, my dear!" was the severe reply. "For my part, I got tired of hearing the Rose called the queen of the flowers when I was a little girl, just as if queens have any more beauty or fragrance than other people. I have never seen a Rose since, but what I have thought of the invidious comparison. And there's the Carnation. Such a name!"

Just here I stammered out some apology, and made my escape. I wanted to keep some of my darlings unsullied. It does seem, when you are in company with some people, as though they would not leave you one beautiful thing to enjoy.]

Wilson brought up the report of the Public Petitions Committee on the petition of thirteen inhabitants of the province of Canterbury, praying for the repeal of the Canterbury Thistle Ordinance, 1866.

Mr. Rolleston moved that the report be printed. In the debate which ensued on this motion,

Mr. Stafford said that he believed it was absolutely impossible to prevent the spread of Thistles, and that a great deal of money was spent in doing only what would be like a drop in the ocean. He had, perhaps, peculiar opinions on the subject, but he believed that Thistles were really no injury to a country, but were a great improvement to second and third-rate land; so much so, that a friend of his had, in reclaiming third-rate land, actually sowed Thistles on it as fertilisers, and valuable Grasses were induced to grow when the Thistles died out, which they did in a short time where the ground was not ploughed.

Mr. Kerr, in referring to this statement, said that he knew that at Panmure, in the province of Auckland, the Thistles had taken complete possession of some very rich land, so much so that nothing else could grow where they were.

Mr. Fitzherbert, after stating that the extirpation of Thistles was, in his opinion, absolutely impracticable in a country like New Zealand, abounding in waste land, and whose cultivated farms adjoined millions of acres owned by the natives, said that he thought the cutting down of Thistles on the waste lands was a great mistake in reference to pastoral lands. He could state from experience that during certain portions of the year the Thistle was an excellent article of food—that period when there was a lack of rain. At that time sheep fed with great advantage upon the flower of the Thistle, and it would, in his opinion, be a disadvantage if the Thistles were destroyed upon the waste lands. In addition to that, the Thistle, by boring down into the soil with its tap root, loosened it, and rendered it thereby much more capable of improvement. Where these immense beds of Thistles grew, they gradually gave way, and in time the place became covered with a thick growth of grass. He had paid considerable attention to this question, and in the eradication of Thistles he had seen great errors committed. Where, then, was the remedy for the complaints made? In England, there were cases where farmers brought actions against their neighbours who allowed Thistles to grow to the detriment of the farm land in the vicinity, and damages were recoverable at common law where neglect had been proved; but to have an inspector, and penalties laid down, would be, to his mind, a mistake, and would prove to some extent an act of oppression.

Mr. Rolleston's motion was eventually adopted.

THE GREAT PEAR ORCHARD OF SANTA CLARA COLLEGE, CALIFORNIA.

The grounds of the Santa Clara College contain many vigorous specimens of fruit and ornamental trees. In these gardens we see growing the Palm tree and the Olive, the last over forty years of age, while not far off is the Fig tree, one of the most beautiful of all ornamental shrubs while young. Yet we find here, amidst these evidences of tropical vegetation, a fine hedge of Arbor-Vitæ, 15 feet high—north and south in juxtaposition; how striking the contrast! In the same garden are gathered over one hundred varieties of Grapes, mostly foreign, thriving in the open air with the slightest attention, and all in fruit. As I looked upon the uniform success that attended the culture of the Grape here, where every Vine is sure to produce its fruit every year, where there is scarcely the possibility of a failure of a crop, and everything is almost as sure as the fixed laws of the Medes and Persians, I turn my thoughts backward to our Atlantic slope, where our vineyardists struggle on, year after year, hardly depending on more than one good crop out of every three, and where prices are constantly fluctuating; where early frost nips their fruit before it is all marketed; where mildew cuts short the health and productiveness of their Vines, and a score of discouragements, which form a remarkable contrast with the ease of the Californian grower; and yet we would hardly exchange places with him. Where Grapes thrive with such abundance, they are too cheap to be profitable. I suppose the average profits per acre of Grapes on the entire Pacific coast is 60 dols. per annum, and yet how common it is for our Eastern vineyards to yield from 200 to 600 dols. per acre. We suppose an acre of Concord, in full bearing, will not fall below 100 dols. nett, while at the low price of 10 cents per lb.; they will more often yield 200 to 300 dols.

At a little distance from the College itself is the enclosure containing the Pear orchard we have referred to. Here are now six hundred trees of about sixty years of age, laden down with the most astonishing crop of Pears we ever beheld. The trees, although old, would average about 30 feet in height, and have a diameter of 10 to 15 feet across the branches. All of these trees would average about a foot in diameter of the trunk, and we estimated a safe capacity of 5 to 10 bushels to

THISTLES NOT A NUISANCE EVERYWHERE!

We know that at the Antipodes—that is, about Australia, New Zealand, and islands thereabouts—the people are standing on our globe with the soles of their feet towards ours; we also know that when it is midsummer with us it is midwinter with them, and now it seems that Thistles with them are the cultivator's blessing. We extract the following from the *Otago Witness* :—

In the House of Representatives, on the 28th of July, Mr. Cracroft

each tree, while on many the production would be fully 5 barrels, Years ago, when fruit culture was not so widely extended as now, the produce of this orchard brought an annual income to the College of over 24,000 dols.; but now, so plentiful and cheap are fruits of all descriptions, that the best terms of sale last year could hardly reach above 100 dols., and thousands of bushels were left to rot on the ground, or fed the hogs. We estimated at least 5000 bushels of prime fruit upon the trees at the time of our visit, and if it could have enjoyed a market like New York the lowest value we could have placed upon it would have been 10,000 dols. It is now a worthless property as a productive investment, and already two hundred trees have been cut down, preparatory to the devotion of the land to other purposes. The varieties we noticed most freely grown are the Easter Beurré, Bergamot, Madeleine, President, Bartlett, Beurré Clairgeau, with a few of our most popular eastern sorts. The President Pear is perhaps the most productive of all, the branches hanging down completely covered with specimen Pears of fine size and colour. The Pear, as a fruit, is quite as successful here as the Grape. All varieties do well. The Californian horticulturist has none of the anxieties we Eastern fruit-growers feel whenever we make our selection of varieties. With us we are fearful of the blight, or anxious as to climate, soil, and popular preferences in the market; but in California the grower sticks his graft upon his tree, or his young shoot into the ground, and in less than eighteen months he has his crop of fruit as perfect and luxuriant

as heart can wish. Every variety succeeds, and only [needs careful planting and culture.

We notice that after the Pear trees have grown for ten or twelve years, their full stature seems to have been attained; they make little or no new wood growth, and seem to stand still, bearing themselves almost to death. Year after year they bear heavy crops without cessation, and it seems hardly possible they can stand such constant and tremendous strains without sooner or later exhibiting signs of exhaustion. However, most of the orchards are young. We see as yet no signs of decay or wearing out. The old orchard of the College is still a marvel of luxuriance.

Among these Pear trees are planted some beds of Strawberries. Time was when a little bed of half an acre yielded an income of 500 dols. per annum, but that time has passed, and now the most they can obtain is but 60 dols. Their berries are large and splendidly coloured. The Wilson, particularly, we would hardly recognise. It has the same shape, but changes its dark red colour into one of brilliant crimson; loses some of its firmness, and almost all of its acidity. We found it here quite agreeable eating, pleasant and spicy, with but little sourness or tartness. Still it is not their most successful variety. The Longworth's Prolific is far more popular and profitable.

They begin picking the fruit about the 1st of May, and it continues ripening down to the 1st of November. As high as 10,000 lbs. have been gathered from three-quarters of an acre.— (*Horticulturist.*)

CASTLE HOWARD.

THE SEAT OF THE EARL OF CARLISLE, NEAR YORK.

No. 1.

CASTLE HOWARD is finely situated in an extensive park. Dignified and majestic in a very high degree, this magnificent building is worthy of its position and its surroundings with which it is in complete harmony. To those at all acquainted with architectural history, Castle Howard recalls a time when many noble mansions were built, in the designing of which a prominent part was taken by its architect, Sir John Vanbrugh,

post and dramatist as well as architect. This noble pile forms a fitting shrine for the rare and costly collection of art treasures with which its stately apartments are so richly decorated. The walls are crowded with paintings by many a famous hand, and I believe I am correct in stating that the interior of the cupola was painted by Antonio Pelligrini, a contemporary of the famous Sir James Thornhill. The south front (*fig. 1*), is

Fig. 1.—Castle Howard, south front.

richly embellished with Corinthian columns, statuary, and balustrading, and a fine flight of steps leads up to the grand entrance, past which sweeps a noble carriage drive in a straight line of half a mile.

Viewed from this position, overlooking the lake and pleasant undulations of the park, the scenery is very fine. The lake is a magnificent sheet of water, nearly one hundred acres in

extent, and from all sides of it the park rises gently, swelling into banks, agreeably diversified with finely-disposed groups of noble timber trees. An important feature in the view beyond the lake is the Mausoleum, (*fig. 2*), designed by Nicholas Hawksmoor, a pupil of Wren, and an assistant of Vanbrugh's in building Castle Howard. The position is well chosen, and the dense masses of umbrageous foliage on each side, while not approaching

sufficiently near to obstruct the view or mar the dignity of its appearance, yet serve to impart an air of retirement and solemnity to this abode of death.

There are no abrupt eminences nor steep declivities here, but that broad expansiveness, both in the green turf and the water, that aspect of grandeur and importance, so well in keeping with

Fig. 2.—The Mausoleum.

those noble old trees which, like a gallery of quaint old portraits, tell of generations and times long since past.

To the right of the lake, and immediately opposite the south front, is the flower garden (fig. 3). This view will serve to convey some idea of its large size and architectural embellishments,

consisting of balustrading, statuary, tazzas, and Grecian vases. The elegant building on the rising ground to the left is a Temple of Diana, which, with the bridge and a glimpse of the top of the Mausoleum towering over the trees, adds very much to the effect of the scene. The design of the flower garden

Fig. 3.—The Flower Garden.

consists of some elegant and very elaborate scrollwork in Box embroidery, the narrowest and most intricate parts of which contain Derbyshire spar, producing a chaste and pleasing effect. The scrollwork was connected with many large beds well filled with plants arranged in very good taste, the principal masses consisting of well-known varieties of Pelargonium. A mixed

bed of Pelargonium Le Grand and Countess of Warwick, with Verbena venosa, had a very good effect. Pelargonium Flower of Spring surrounded by Verbena Purple King, was equally fine. Golden Feather Pyrethrum was very bright and effective. During the past summer I have seen this useful plant largely grown in several gardens which I have visited in different parts

of England, and it invariably presented a most satisfactory appearance. This is noteworthy, because from the ease with which a large stock of it may be raised in spring from seed, it must be a very valuable bedding plant, especially to those who have but little glass accommodation.—EDWARD LOCKHURST, *Old Lands, Buxted, Sussex.*

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE Globe Artichokes should now have some of the superfluous leaves cut away, and the stems earthed-up 6 or 8 inches. Surround the plants with recently fallen leaves, and cover these with soil, forming a sort of mound; then thrust a wisp of straw or hay in the centre of the crown. Take up the *Jerusalem Artichokes* and house them dry in a dry shed. *Cauliflowers* in head should be taken up and heeled-in close together, covering them with long litter in severe weather.

FLOWER GARDEN.

Let the planting of autumn bulbs be completed as soon as possible. Take up all Dahlias when the tops are frosted; do not clear too much soil from them, it will prove a protection if dried upon them. Strong tubers should be in a warm and airy place in order to get them thoroughly dry; weak ones must be potted or covered with dry soil. Neapolitan Violets should be thoroughly cleansed from weeds, runners, and dead leaves, and have a considerable quantity of dry sand strewed amongst them. This will prevent the ravages of the slugs. Out of doors they must have hoops and mats. Plant out Hollyhocks and other biennials. This is an excellent planting season. Where the ground is duly prepared not a moment should be lost; pruning, thinning, &c., can be done in frosty weather, not so planting. Tulips, as a matter of course, are all planted, and few seasons has occurred in which, to use florists' phraseology, "they have gone in so well." I would advise precautions being taken, as many of the bulbs are in a certain degree affected by the serious mildew which attacked the foliage last season. It will, therefore, be advisable to keep the beds as dry as possible for a few weeks, or, at least, to give the bulbs time to form plenty of roots previous to exposing the beds to the weather. This may be done by covering with mats, &c., during wet weather. Carnations and Picotees had better remain where they are till spring. I am no advocate for their removal in November. Those which are potted off should have the air at all times, and if they have had plenty of exposure hitherto, slight frosts will not affect them. Auriculas, also, should be nursed as little as possible; give only a small quantity of water, and keep them out of the way of drip. Attend to compost heaps, and collect leaves, &c., for next year.

GREENHOUSE AND CONSERVATORY.

At this time of the year it is of the utmost importance to arrange stock in houses so as to give a due proportion of light to each kind of plants, remembering especially those from brighter skies. All retarded autumn flowers should have a situation as much exposed to light as possible—near the glass, and not far from a quiet ventilation. Such plants as the following will deserve attention in this respect:—*Euphorbia jacquiniiflora*, *Eranthemum pulchellum*, *Geissomeria longiflora*, the *Heliotrope*, *Aphelandra cristata*, *Gesnera zebra* and *bulbosa*, *Geraniums*, *Centradenia roses*, *Linum trigynum*, *Mignonette*, *Salvias*, *Calceolarias*, *Cyclamens*, *Cinerarias*, and *Verbenas*. These, if attended to as previously directed, will be gay for weeks, and with *Chrysanthemums*, *Roses*, and *Camellias*, will prevent any blank occurring between the autumn flowers and those of the spring forcing. Above all, let every glass sash receive a thorough washing immediately. Those who underestimate the importance of clean glass in gardening have yet much to learn. In order to keep the glass clean as long as possible, let mats and coverings of all kinds be constantly suspended on rails or posts. This is absolutely necessary, both for the sake of the glass and the sake of economy, as Russian mats are rather expensive. A well-managed conservatory should now boast of a finer display than at any other period of the year. The charming contrast between the dark and glossy leaves of healthy *Camellias* and their lively-coloured flowers, the delightful perfume and gay tints of the *Bourbon*, *Hybrid Chins*, and *Hybrid Perpetual Roses*, with the exuberant and dashing style of the Chinese *Chrysanthemums*, will even unassisted produce a gorgeous effect. Keep a mild and genial atmosphere of 50° to 60° by day, sinking to 45° at night. Let the floors or some portion of the house receive a sprinkling in the evening,

provided a little back air can be given to prevent drip. Syringing is, of course, out of the question. In the mixed greenhouse the Chinese *Primroses* may be removed to a shelf as near the glass as possible, with plenty of air at all favourable opportunities. Herbaceous *Calceolarias* should be treated in a similar manner, and duly attended to with water. *Cinerarias* must be protected from the ravages of green fly by fumigations of tobacco, or by syringing with tobacco water. Some late-flowering varieties of *Heaths* and *Epacrises* will now be growing rather freely, especially those which have received late shifts, great caution in watering them will therefore be necessary. A few *Epacrises*, such as *autumnalis*, will soon become gay with flowers, and are worthy of every encouragement. Should mildew attack any of them slightly dust them immediately with flowers of sulphur. If any of the beautiful tribe of *Tropaeolums*, particularly *tricolorum* and *brachyceras*, which flowered early in the season, begin to grow, they should not be checked, but allowed to grow slowly through the winter; but if there is no appearance of growth, which is best for their future success, the roots should be kept inactive in a cool place, with the soil about them quite dry, and protected from mice.

STOVE.

Stove plants in general as before. Let those *Orchids* which have completed a good summer's growth, and which are somewhat inclined to be deciduous, sink gradually into repose. Those evergreen kinds, as some of the *Dendrobiums*, the *Aërides*, *Saccolabiums*, *Vandas*, &c., on blocks or in baskets, should be lowered a little from the roof, if too near, in order to escape the vicissitudes of temperature to which that situation would expose them in winter.

COLD PITS AND FRAMES.

In the case of cold pits, the time has now arrived for putting in readiness straw shutters, or whatever else it may be intended to use for coverings for them. Straw shutters, if well made, are expensive in the first instance, but are considered by many to be the most efficient of any kind of covering in use, and taking into account the time they last, they are, perhaps, as cheap as any. Expose the stock in such pits to air on every favourable opportunity, so as to check growth and consolidate the wood. The time is at hand when ungenial weather will frequently drive the labourer in-doors, and a stock of work should now be provided for such occasions. The tying of new mats, cutting and picking straws for the walls, cleaning old nails, drawing bast for the next summer, the arrangement of herbs, examining stores, making flower sticks and labels, washing and putting away all spare striking and other glasses, making straw or reed mat-protectors for tender plants, as well as making a stock of besoms and baskets for the ensuing year—are matters of as great consideration as out-door business, and should be proceeded with as soon as possible. Gardeners and amateurs should purchase a liberal stock of Russian mats at this period; in fact, a twelvemonth's supply. These will at once furnish a little in-door labour. Willows should be instantly procured for basketing, and a good stock of cloth for shred-cutting. All superfluous or dead plants in pots should be emptied out, and the dirty pots from every part placed in a corner of the shed, ready for washing in bad weather. Plenty of broken pots should also be housed in a shed corner, to be crushed and sorted in bad weather; they may be fairly reckoned amongst the most important matters connected with the potting-shed. Anyone having old half-worn sashes without glass, may readily make a most useful straw cover of them, well adapted for protecting *Endives* and other salad, *Parsley*, &c., as also for covering early crops of *Potatoes*, *Radishes*, and *Carrots*. They can be made on a couple of tressles. The straw (that of Rye, if possible) is drawn through the hands in bunches, and laid across the longitudinal bars of the sash regularly. When covered equally, three or four long sticks or laths are placed on it in a line with the sashbars, and bound down to the latter with pitched cord. It housed when out of use they will last a couple of years.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Laying Down Strong Broccoli, &c—But for a press of other work, and the unsettled state of the weather, we should have nearly finished this. It is best done on a regular system. The intention is not so much to stunt or cripple the plants in their growth as to protect the stems and heads from frost. By earthing-up, and protecting the heads with a little litter in

severe weather, we have had as fine, or rather finer, heads than when we laid them down, but with a little more trouble. As a rule, if possible the head of the plant should be depressed to the north, and if that does not suit, then let it be laid to the west—the directions in which it is less likely to be acted upon by the morning sun, and therefore so far a security against sudden changes. In laying, begin at one end of a row, take out some earth a foot or so from the base of the plant, and a little, but to a less depth, close to the stem, so as not to injure the roots much; press the head of the plant down without breaking it, and then from the front of the next plant place earth over the stem of the first plant, and so on until all are done. Some dwarf sorts need no laying, and, as stated above, the system is more required in the north than in the south. The leaves laid aslant greatly protect the young head or heart.

Cauliflowers.—The late Cauliflowers, owing to the rain after the sewage watering, have proved very fine this autumn, yielding fine, large, symmetrical heads. Before much frost comes we shall place a lot of young stuff in earth pits to receive protection. Where there is a dry shed, Cauliflower, though it will not look so fresh as that cut from a pit with its green leaves, will keep well and be serviceable for many purposes, if, whilst the heads are still close and compact, the leaves are all stripped off, and the stems cut off, say, 9 inches or more in length, and stuck in earth and sand that is damp rather than dry. The position should be airy, when desirable, be kept free from frost, and but little light should be admitted.

We planted out young plants under hand-lights. It is well that the ground should not be too rich at first, as plenty of enriching matter can be added in spring. We shall try to make use of an old frame or an earth pit for pricking out a lot to stand the winter. For all such purposes we find after planting, an open rough surface, such as sand, is of importance alike for preventing damping and keeping off slugs, &c. Rough charcoal dust, or rough small coal ashes, are also good. Fine ashes are of little or no use in this respect. A lot of plants may now be potted and placed where they may have a little protection. Many are often saved in good condition if pricked out rather thickly at the foot of a wall or fence, the one helping to protect the other, and then when transplanted in spring they come in for the second or third succession.

Potatoes and Root Crops.—Great quantities of Potatoes have been much injured this season by leaving them in the ground so long as to let them have a second growth; otherwise the crops in general have been fine—of good quality and great in quantity. A little lime is very beneficial in all old gardens, also in all stiff clay soils. Carrots, Beet, Scorzonera, &c., will now be better out of the ground than in it. When scarce of dry stuff and storage room, we have found no plan better in a close shed than building them in layers, with dry small faggot wood between them. It is of great importance to take up all these things in dry weather, and to sort them for use according to quality and size. Spruce and larch twigs dried are good for this purpose. By no means use sawdust, as some people recommend. Whatever kind of wood it comes from, and however dry it may be, it is sure to taint the roots; and then by absorbing moisture from them the whole mass will heat, and there may easily be, if not constantly examined, a mass of rotteness instead of wholesome food.

Celery.—The youngest is still growing in these showery days, and the farthest advanced was made safe in dry weather. As we had no ashes to fall back upon, we have used a heap of burnt rubbish, burnt clay, &c., to put immediately round the plants in beds, filling up to the necessary height with the surrounding earth, made fine by breaking and pulverising. This thin casing, given as lately detailed, keeps the stems drier, and, to a certain extent, keeps worms, snails, and slugs from marking them. In stiff ground, but for harbouring snails and slugs, it would be advisable to finish the blanching process with moss, clean litter, dry tree leaves, &c. Sometimes we have used some of these, and just dusted them over with rough ashes. Dry tree leaves put on not so thickly as to heat at all answer admirably, they keep out frost so well, and even in a wide bed they soon cake on the surface, so that when laid on with a proper slope rain passes off them as if from the wing of a duck.

Lettuces.—We took up a number of good plants and put them in an earth pit, where they could be protected; the earth pit just being cleared of bedding plants, as they are removed to the dormant fruiting houses, where they will be more safe for a few months of the worst part of the year. Pricked-out Lettuces to give them a chance of standing, and sometimes they do better in the open ground than at the foot of fences or on

the sides of raised banks. The young plants on sloping banks are growing rather too freely since the showery weather came.

Endive we covered with dry leaves, slates, &c., to bring it in for use along with the Lettuces. Though most people like Lettuces better, yet the Endive looks very nice in the salad bowl.

Rhubarb and Sea-kale.—There has been little time taken or needed in preparing these for forcing this season, as the dry weather of the summer caused their leaves to wither rather prematurely, but the buds seem very fair, and will no doubt do good service when called upon. *Asparagus* is now fully ripe, and will be cleared off as soon as we can find time. Some correspondents have been inquiring as to giving salt to these seaside vegetables now, and we would say that a little sprinkling would do no harm, and if kept from the buds of Sea-kale, it would prevent slugs and even birds from touching them much. There is no better deterrent to soft-skinned intruders than salt where it can be applied with safety; and we have noticed that mice and birds have turned away from such things as Sea-kale buds because they found the soil near them saline. The chief time to apply salt is, however, after growth has freely commenced; in fact, could we do it, we would liquid-manure these plants in summer, and a little salt and mulching then would answer well. The summer, especially such as the last, forces us to let the above plants take their chance, except giving a sprinkling of salt, and we often notice how comfortably moist the ground of the *Asparagus* and *Sea-kale* is, contrasted with other crops, merely from the sprinkling of salt given in the middle of June. When a piece of *Asparagus* is to be raised for forcing, it will pay well to gather little or nothing from that piece in the preceding spring and summer. It will thus ripen and rest earlier. Such may well be expected to do better than an old exhausted bed; done away with as the worst, but "good enough" to be forced. Vegetables to be forced cannot be too good of their kind if the gathered produce is to be good in quality and quantity.

We do not intend commencing forcing *Asparagus* and *Sea-kale* just yet, having a regard to our stock, but frequently we have had both in fair condition by the middle of November. *Rhubarb* we have never had so early. Treat it as we may, that is not good in proportion to the others. Contrary to either *Sea-kale* or *Rhubarb*, *Asparagus* likes air and light to attain colour, but we have frequently forced it in the dark, cut it when 6 or 7 inches long, and set the bottoms in damp sand or moss close to the glass in a warm greenhouse for two or three days to give it a little colour. A great check in temperature in forced *Asparagus* is apt to make it hard instead of sweet and juicy.

FRUIT DEPARTMENT.

There are but few traces now of the dry season, but some of its results, as the absence of our late Peas, are felt. Strawberry plants planted out and turned out of pots still present a stunted appearance. We lost whole rows of some large turned-out plants, even after they received one or two waterings, and were shaded with evergreen boughs when water could not be given. Plants in pots were supplied with liquid of some sort, as they could not do without it, though even these Strawberry pots we had frequently to shade to save the watering we could not give. These, however, partly owing to the sewage given, are rather stronger than we like to see them.

We have said so much of cleaning, &c., lately, that we will just add one word on the keeping of late Grapes. In mild weather it will be advisable to give a little fire heat every day, and chiefly in the day, with air early given, or rather kept on night and day when there is no frost. Drip must also be avoided. Drip is easily got rid of in large squared fixed-roof houses. In old houses with the old form of rafters, even though the glass and putty are sound, much drip often comes from the rafter, first from the want of a deep plough-line in the centre of the rest of the rafter for securing the sash; and secondly, from that line becoming choked-up in time from dirt and dust.

ORNAMENTAL DEPARTMENT.

Referring to previous notices, we shall just allude to two matters. First, to direct the attention of young gardeners to diagram no. 3, page 301, as to the mode of making a perpendicular cut for Box edgings. It is more easily made bevelled, and is too often done so, and the consequence is the gravel has more earth at the sides, and is more troubled with earth heaps.

The second matter is, we are now inserting in a cold pit our *Calceolaria cuttings* for next season. The mode has frequently

been described. We never let them have a pot. We prick them out in fresh sandy loam in rows 2 inches apart, and 1 inch from each other in the row. We like them best to root little until after Christmas, and by the middle of March we transplant into earth pits from 4 to 9 inches apart, where they can receive a little protection when necessary, and then we lift them with balls as fine strong plants in May. The plants growing in the beds, we do not require to plant them so early merely to get room or avoid watering. *Amplicaulis* will not stand so much cold and damp as the others; in fact, unlike most other things, *Calceolarias* for beds seldom feel the effects of damp. A cool moist soil and a bright sun are their delight. Notwithstanding the dry summer, *Calceolarias* succeeded almost as well with us as *Geraniums*. That was greatly owing to mulching, which kept the roots cool. Even now (October 29th), many plants are pretty full of bloom. For cuttings we prefer small side shoots about 2 inches in length.—R. F.

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

THE REV. W. F. RADCLIFFE requests us to say that his direction is Okeford Fitzpaine, near Shillingstone, and not near Blandford.

MEDICAL QUALITIES OF BRITISH PLANTS (*D. H.*).—Dr. Thornton's "Family Herbal" contains the information you seek.

PARK AND GARDEN (*Latent*).—It is impossible to suggest the proportions the park, lawn, flower garden, kitchen garden, and shrubberies should occupy in forty acres, without knowing the tastes, requirements, and pecuniary means of the family.

ADVICE ASKED (*A Youthful Aspirant*).—The little Manuals published at our office are useful. In addition to them we would advise you to obtain the "Science and Practice of Gardening," price 3s. When you have mastered these obtain "The Cottage Gardener's Dictionary," and when you can spare the money, "The Gardener's Assistant," by Robert Thompson, which is 31s. 6d. By the time you have studied the smaller of these works you would be able to ascertain better the bent of your own mind. As you are only nineteen, you would not find much difficulty in getting in as under gardener to a large garden, more especially if your employer would recommend you to one of our large nurserymen. As, however, you have done well in a small place, we should hardly like to advise you how to act, as with prudence you may work your way from your present place to a larger one, and then to one larger still. Though by thus acting your wages ultimately may be much less than those holding the best places, you must recollect that all along you would be getting much better pay than a mere improving young gardener could hope to expect. In most small good places the gardener is paid for his work. Improving young gardeners we say nothing in defence of the system, but merely look at it as it is) must ever consider the means of improvement as a part of their pay.

TRANSPLANTING LARGE PAMPAS GRASS (*W. T.*).—The best time in our opinion to move the large Pampas Grass would be at the end of March next year. It might be moved now if you could make sure of a good ball, on which depends the success of the operation now or in spring. The grass should not be cut away if the plant is moved at this season. It ought to remain until the beginning of April.

REPOTTING ROSES (*Idem*).—Pot them now, and place them in a cold pit, giving plenty of air. As they have not been potted off two years you could not do worse than give them a large shift. We advise a moderate shift, removing as much of the old soil as can well be done, care being taken of the roots. The plants will flower in March in the greenhouse.

FRENCH PELARONIUMS TO FLOWER AT EASTER (*Idem*).—The plants should at once be shifted into 4½-inch pots, and have a light airy position in a house with a temperature of from 40° to 45° from fire heat, and at the end of December they should have their blooming pots (6-inch). They should not be stopped after this, and after February they should have a temperature of from 50° to 55° from fire heat, affording them abundance of air and light, and keeping the shoots regulated.

CUTTING OUT THE WOOD OF ROSES (*E. F. W.*).—We approve of your now cutting out the old, weak, useless wood, and also thinning the shoots, deferring the principal pruning until February or as soon after as the weather is mild. You may, however, do all in spring.

ARBITUS PROCERA TRANSPLANTING (*J. R.*).—This is a good time to remove evergreen shrubs; but as you are thinning out, perhaps you will remove it to a more open situation, to which case the plants, from losing the shelter they had when close together, are liable to be somewhat injured by the wind and severe frosts after planting. We consider the beginning of March a good time to move the *Arbutus*, and better than late in autumn. The best time of all is the end of summer or early in autumn, as soon as the ground becomes moist and the growth of the plants is completed and the wood firm.

PLANTS FOR A NORTH BORDER (*Mrs. B.*).—There is little hope of getting anything to grow where Ivy does not; but we have found *Cotoneaster microphylla* do well on a north border, and the Spurge Laurel, *Alexandrian Laurel*, *Dutch's Broom*, *Berberis dulcis*, *Vincas major* and minor, and the gold and silver varieties of the last; *V. elegantissima* being very fine, and doing well almost everywhere. *Skimmia japonica* will grow in a shaded border, and is finer there than in a sunny one. *Aucuba japonica* is also good. We have no doubt if you give the above a fair amount of soil, and tolerably rich, that they would do well.

POTATO-GROWING FOR THE LONDON MARKET (*A Novice*).—You do not say whether you intend growing early or second early sorts, but we presume both. Ashleaf and Myatt's Prolific we advise for early crops, and Lapstone and Early Oxford as second early sorts. The first three are kidneys, and the last a round kind. They are good croppers, and of excellent quality. The Potatoes would be best sent to market in hampers

—indeed that is the only suitable way of sending the early and second early sorts before they are ripe or have the skins fixed. Apply to a dealer in the Borough Market.

EARLY PEAS AND POTATOES FOR MARKET (*A Subscriber*).—Sangater's No. 1 or Daniel O'Rourke is the best early Pea; but Emperor or Morning Star is preferred by many on account of its free bearing, though it is not more so than the former. A pint will sow a row 20 yards long, and if the rows are 3 feet apart you will require about 3½ bushels per acre. The best early Potato for the open ground is Myatt's Prolific Ashleaf; but the old Ashleaf comes in about a week or ten days earlier.

WINTERING FANCY PELARONIUMS (*An Amateur, Halifax*).—Without a greenhouse it is difficult to winter these plants. Your only plan will be to keep them dry, not giving them any water beyond that needed to keep the leaves from drying, and you cannot keep them too near the glass as long as they are safe from frost. We think the plants have gone off through damp. For mixing with blood to apply to Apple and Cherry trees, we know of nothing better than dry soil.

BRICK DUST FOR UPLAND PASTURE (*East Norfolk*).—If made very fine it may be of some benefit, but we question very much its utility unless the soil is heavy. Upland pastures are generally too dry already, without adding anything of a nature calculated to burn in dry hot periods.

GRAPES NOT KEEPING (*H. P.*).—Many would be quite satisfied with such fine Grapes up to this time, from starting in March, though they would not keep until January. The good keeping depends on the Grapes getting ripe, but not over-ripe, in autumn, giving them plenty of air of a temperate character, and keeping them dry, but not parched. When fire heat is applied, air should also be given to prevent any resting of moisture on the berries. Your taking out all the plants, and keeping the house dry, would almost lead us to conclude that the damping and going-off are partly owing to over-ripeness after such a bright summer, but chiefly owing to the damp that you say enters the house, we presume from broken or cracked sashes, or exhausted puttying. See page 326 on these matters. If dews or rains get in over the bunches, it is next to impossible to keep them fresh.

VINES IN A GREENHOUSE (*Henri, Lisburn, Ireland*).—For your greenhouse vineery we would not have more than four Vines—viz, two of Black Hamburg, one Buckland Sweetwater, and one Muscat Hamburg or Royal Muscadine. The border for the Vines we would make either chiefly or altogether on the surface of the present soil, and nothing is better than fresh loam from the top of a pasture which has been well exposed to the air, enriched with broken bones, and kept open with a little charcoal and rough lime rubbish. If we knew the circumstances and the position of the border we might say more. See the "Vine Manual," which you may have by post from our office for 2s. 8d.

POT VINES (*A. R. Q.*).—The Vines you intend for fruiting next year ought to be potted now if they are in less pots than those 11 inches in diameter; and in potting, the roots should not be disturbed, merely loosening the sides of the ball, and removing any loose soil; 13 or 15-inch pots are not too large. We think potting after they showed fruit would prevent its swelling, and planting in an outside border and fruiting the Vines the same season, we think would not prove successful. If you plant them out, their roots should be disentangled and spread out, and they should not be allowed to bear fruit the first season.

KEEPING BERBERIES ON THE STEMS (*Berberry*).—Is it the common Berberry you mean? The fruit is apt to fall, but we have known it kept for a long time by cutting the twigs before the fruit was quite ripe, and setting them in sand in a dry, cool place, and when the leaves decayed taking them off, and running weak gum arabic along the base of the fruit. The splendid winter plant, *Crataegus Pyracantha*, can generally be obtained without any trouble, as birds seldom meddle with it. The dark purple berries of the evergreen Berberry, *Berberis Aquifolium*, often stand well through the winter.

BEES ON TREE (*Rector, Dorset*).—We approve generally of the proposed mode of arrangement. Your blank wall of the school-house would look well if covered with *Cotoneaster microphylla*, or *Crataegus Pyracantha*. We fear that *Picea Pinus* would be too large for the position No 6, but if you have an Irish Yew at No. 2, you might have the same or a Juniper at No. 6. Then we would make 4 and 8 *Cupressus Lawsoniana*. No. 5, we would bring nearer to the walk to harmonise with 10, and if you had *Cotoneaster* against the wall, then 5 and 10 might be alike. We like the idea of the open space of lawn in the centre, and before the shrubs grew you might have little beds for flowers close to the walks.

ROOTS OF FIG TREES (*B. B.*).—It is not absolutely necessary to brick in the roots of Fig trees, but if the roots have free scope, they will be apt to grow too much, and the shoots will become too luxuriant for free bearing. We have seen Fig trees ripened with great propriety to check luxuriance. We have seen one half of a tree as distinguished for fertility as the other half was for barren luxuriance, because the one half had been nibbled with mice. Eighteen inches in depth, and from 3 to 4 feet in width, we consider space enough for a good-sized Fig tree. We have seen fine crops with no more width of soil than 3½ inches. This, however, must be kept in mind—the less the space enclosed the greater the care required in watering. If the soil becomes dry at critical times the fruit will drop to a certainty.

VERONICA (*Jonas*).—Several of the Veronics are now used for bedding purposes, and as we do not know whether you allude to the flowers or the foliage, we are at a loss as to what the variety is respecting which you wish for instructions. It may be one of the small shrubby kinds, mostly with blue flowers, and increased by cuttings of the growing parts inserted in sand in a gentle hotbed, except in July and August, when a close cold frame will do. There is a variety with "grey" or silver foliage—viz., *V. candida*, which is increased by division, and by cuttings or slips early in summer. Send us a specimen.

CRAIG'S PROLIFIC EARLY OCTOBER (*J. C.*).—We received a brace growing from one branchlet. They were nearly of similar length, 14 inches—the most serviceable of sizes. They were short-necked, blossom adhering, white-spined, quite straight and regular in form, flavour good.

FORMING A POND (*C. B. M.*).—The bottom and sides of the excavation should be taken out or down to a good hard bottom, and before putting in any clay, ram firmly. We would then put in a thin layer of dry clay and ram it firm, and this first layer should not exceed 3 inches thick. We would on it place about 2 inches deep of gravel and ram well down, then put on a layer of clay, adding water so as to make it ram well among

the gravel. It is bad practice to add too much water; all that is wanted is to get the clay to such a state as to ram well and firmly. Add layers of clay until you have a foot thick of hard rammed clay, and then you may finish off with about an inch of gravel. That is how we make ours.

IRISH YEW TRANSPLANTING (*Subscriber*).—Now is a good time for its removal, which may be easily done, taking care to preserve as much soil as possible about the roots. After planting, give a good watering to settle the soil about them. The Irish Yew is increased by seeds gathered now, laid in a heap until spring, and then sown in light soil, and many of them will grow next year, but some will not vegetate until the following season. It may also be increased by cuttings 6 or 8 inches in length taken off with a heel, which should be pared smooth; and after removing the leaves from the lower half insert the cuttings in sand in a shady border, and cover them with a hand-light. April and August are the most suitable times to put in cuttings. Seedling plants are best.

ADIANTUM CAPILLUS-VENERIS FRONDS BROWNING (*Idem*).—We think the browning of the fronds is owing to the plants being covered with the bell-glass, which we suppose is not taken off daily and the inside wiped dry. Before you report the plant try the effect of doing this. Remove the fronds which are most affected. You may report now, but we should prefer the beginning of March. You may sow the spores now with every chance of success, taking care to cover them with a bell-glass, and keep the surface constantly moist.

HONEYSUCKLE PROPAGATION (*C. W. D.*).—Now is a good time to put in cuttings. They should be of the ripened shoots of the current year cut into lengths of three joints each; two should be inserted in the soil, leaving but one above the surface. A sandy soil in a shady border is the most suitable position. If the joints are far apart the cuttings need only have two joints. The less of the cuttings out of the soil the better. Layers, however, are a more certain mode of propagation, and may be made now.

CLIMBERS FOR A NORTH WALL (*M. L. D.*).—The best plant for the mortar wall would be Ivy, which should be trained and nailed so as to keep it from falling if there is any likelihood of its doing so. *Cytisus microphylla* would answer for the cement wall, but it would be necessary to nail it; and, indeed, there are no plants that would cling to a cement wall without being secured against it. Both the Pampas Grass and *Tritonia aurea* would not succeed on a lawn at a high elevation and in an exposed position north of Lancaster. The *Tritonia* is with us a poor lawn plant, and we think you meant *Tritonia Uvaria*, which succeeds admirably much farther north, also the Pampas Grass except in bleak positions. Now is a good time to plant the creepers.

PLANTING PEAR TREES (*H. M., Dublin*).—Let the upper roots be no more than a foot below the surface, and mulch over them in summer. No planting is much worse than deep planting.

LABELED (*Ocorghina N.*).—Use zinc labels, and with a quill pen write on them with the following ink:—Sal ammoniac powder and verdigris, each 1 drachm, lampblack half a drachm, mixing with 10 drachms of water. The labels should previously be scoured with sand paper.

CINERARIAS FAILING (*A. Z.*).—We think that the soil you have grown them in is too poor and too light. Try the following compost:—Turfy loam from an upland pasture, two parts; fibrous peat, one part; decayed leaves, one part; very rotten cow dung, half a part; and a small addition of river sand. Water your present plants with weak liquid manure.

LEAVES FOR BOUQUETS.—The leaves of the Stag's-horn Smack may be preserved with all their beautiful autumnal tints by pressing them in a book. Such leaves make a splendid background for winter bouquets, and are very ornamental alone in vases for the mantelpiece.—G. BUNYARD, *Maidstone*.

SELECT INDIAN AZALEAS (*Colonel B.*).—Admiration, Brilliant, Cheloni, Criterion, Duc de Nassau, Etoile de Grand, Extracel, Flower of the Day, Ghodstanes formosa, Grand Duc Michel, Her Majesty, Iveryana, Kinghorni, Madame Mieliez, Mars, Stella, Vesavius, and Stanleyana. The *Pelargonium* you name are good.

ALLAMANDA VIOLACEA AND CULTURE (*J. Bayly*).—Like the rest of the genus it is a climber, but may be grown bushy. Its flowers are lilac-coloured, and open at the end of September and during October. It is a native of Brazil, and requires the same culture as the yellow-flowered species, thus well detailed by Mr. Williams in his "Choice Stove and Greenhouse Plants." "If allowed to make long growths they will require a trellis, the most desirable being that of a balloon shape; but the best system of growing these plants is to prune hard back in the spring, just before the buds start, after which the young shoots should be pinched back once or twice, to induce them to throw out laterals, and thus to make a bushy plant. When treated in this manner a few stakes only will be necessary to give them uniformity and symmetry in shape and appearance. The soil should be composed of equal parts fibrous loam, peat, leaf mould, and silver sand, with the addition of a little well-decayed manure. When potted, the plants should be placed in a temperature ranging from 65° to 75°, and as near the glass as possible, and they must be treated liberally with water from the syringe until October, when it must be gradually withheld. In spring they will want repotting, and to be again treated in the same way, when they will soon throw out blooming laterals. If required to bloom early they must be started early in the month of January." *A. violacea* seems to require a little more nourishment than the other species. Give it weak liquid manure once a week after the bloom buds are apparent.

HEATING A CONSERVATORY (*Wild Wind*).—You can heat the conservatory with the north aspect, provided, if the top of the boiler is a close one, the pipes in the house are higher, not lower than the boiler. If the boiler has an open top your flow pipe might be level all round, and 6 inches below the top of the boiler, the return entering near the bottom of the boiler. With a close boiler you can take the pipes pretty well as high as you like, if not higher than the feeding pipe or cistern, but you cannot take the hot water beneath the level of the boiler. The easiest mode for connecting the pipes with the boiler is to use 1-inch strong gas pipes to screw into the boiler; on these you could have taps. In such a house, besides Ferns and Mosses, you could grow Camellias and the fine-foliated Begonias, &c. Ferns, Mosses, and Begonias, with a few Dracenas, &c., would make an interesting house.

NAMES OF FRUITS (*A Twelve-years Subscriber*).—If your Grape is a Muscat, as you say it is, you must not expect it to ripen out of doors. It must not only be under glass but the house must be artificially heated.

(*B. B.*).—Apples: 2, Court-Pendu-Plat; 3, Franklin's Golden Pippin; 4, Reinette du Canada; 5, Court of Wick; 7, Golden Winter Pearmain. Pears: 1, Fondante d'Automne; 3, Aston Town; 4, Doyenne Masqué; 5, Doyenne Blanc. Others not recognised. The Pears were decayed. (*Della*).—Beurre Nantais. (*C. S.*).—1, Brookes' Pippin; 2, Christie's Pippin. (*W. Thomson*).—Not known, very astringent. (*J. M.*).—Api noir. Send a fresh specimen of the flower. (*An Old Subscriber*).—It is a very fine specimen of Warner's King. (*J. A. H., Suffolk*).—Pears: 17, Gloa Morceau; 8, White Doyenne; 15, Swan's Egg; 16, Dunmore; 13, Marie Louise; 9, Beurre de Racee. Apples: 6, Downton Pippin; 18, Scarlet Pearmain; 19, Coe's Golden Drop; 4, Cambridge Pippin; 7, Gros Faros; 5, Striped Holland Pippin; 1, Golden Noble; 3, Court-Pendu-Plat; 2, Nonpareil. (*H. S.*).—The Grape is one of the many vineyard varieties cultivated for the vintage only, and is neither cultivated nor worthy of cultivation in this country.

NAMES OF PLANTS (*H. Armytage*).—We cannot name plants from leaves only. No. 4 is *Berberis Darwinii*. (*W. M.*).—The same answer applies to your specimens. (*H. Mason*).—1, *Garrya elliptica*; 2, *Veronica spicata*; 3, cannot be identified from such specimens; 4, *Laminium maculatum*; 5, *Onithogalum albiaceum*, the "Onion plant" (*B. B.*).—1, *Escallonia imbrata*; 2, *Cupressus orientalis*; 3, *Phlo* is *Leonurus*. (*An Old Subscriber*). 1, *Garrya elliptica*. You ask if this shrub flowers. Certainly it does, and now and for some little time past is its season; indeed, the post has just brought us a flowering specimen to be named, which you can have by sending your address to the Editors; 2, *Bupleurum fruticosum*; 3, *Perinetia mucronata*. (*Halstead Correspondent*).—1, *Giulia coronopifolia*; 2, *Penstemon gentianoides*; 3, *Tricyrtis hirta* (*E. M. B., Enfield*).—Your plant is without doubt a species of *Bauhinia*, we should say it is *B. purpurea*, a native of India; if your seeds are from Demerara they cannot be from wild plants. (*A. M.*).—1, *Adiantum Capillus-Veneris*; 2, *Pteris longifolia*; 3, *Scolopendrium vulgare*, var. *convolvere*; 4, *Phloxis Lecouras*. (*Colonel Bingham*).—1, *Lastrea dilatata*; 2, *Doodia caudata*; 3, *Pteris serrulata*; 4, *Asplenium marinum*; 5, *Athyrium Filix-femina*, in a very young state.

POULTRY, BEE, AND PIGEON CHRONICLE.

PRIZES—JUDGING—REPORTING—BUYING.

My attention having been directed to a letter of Mr. L. Wright's, in the Journal of October 20th, in which he requests me by name to give an opinion on various subjects he mentions in reference to poultry shows, I comply with his request as plainly and briefly as possible.

In the first place, then, I am by long experience well assured, as Mr. L. Wright very correctly states, that too great a difference in the value of the prizes in each class materially lessens competition. To secure, therefore, the most entries, combined with the best pecuniary results to the show, if I had the regulation of £10 to each class I would divide it as follows—£4, £3, £2, £1, being four prizes, thus giving one extra chance of winning to each entry over our present general rules, and also bringing the prizes more in accordance with the relative perfection of the pens exhibited.

Mr. L. Wright proceeds to suggest the expediency of giving in "order of merit" all the highly commended pens, adding, "nothing could be more easy." I, on the contrary, contend nothing could be more difficult; nor do I conceive that any individual at all experienced in the arbitrations of a large show would by any possibility have urged such a suggestion. And why? Not unfrequently the time at first appointed renders it necessary that the arbitrations should be completed at the rate of something like one hundred pens an hour. Unlooked-for delays very often bring with them much abbreviation of the time first allotted; and yet, to add to this already too great restriction, Mr. Wright asks that the several highly commended pens in the majority of the classes as they happen to arise, shall be placed in their "relative order of merit," and repeats, "nothing could be more easy." It will, on the contrary, be only too vividly photographed on the memory of all practised judges, that the award of even a third prize often takes twice the time and trouble that was required to decide on the first and second prizes, and proportionably as you descend into the ranks of mediocrity so do the difficulties become greater and greater, until at length, as you get to the lowest grade, the Irishman's assertion quoted in Mr. Wright's letter becomes pretty near the fact—viz., "That one was as good another and a great deal better." Certainly, then, any judge would require fivefold the time at present given to overcome this increased difficulty, than which, Mr. Wright says, "nothing could be more easy." I am assured that a little personal practical experience, were he individually to try his proposed plan, would be all that is wanted to convince Mr. Wright of its utter impracticability; and I cannot but think he is now fruitlessly expending as much time and money upon this matter as he now admits he did in his efforts a year back respecting "trimming," which all of us disapprove; but some of the very first on the list of protestors proved among the very earliest to be

"caught," and "disqualified," for actually sewing cocks' combs through and through to keep them upright.

But many of our amateurs may ask—How can these things be remedied? I rejoice, by employing additional judges, and thus giving them sufficient time. Not, be it supposed, by sending three or four gentlemen together, for that only retards progress, but let each have his appointed section, allotting from sixty to seventy pens an hour in the general classes, and considerably more time to all varieties of Game fowls, as the majority of the best of these birds should be "handled." But at once this brings the almost general veto of committees. "Our receipts," say they, "do not allow of our employing more than one judge," even should he request simply his travelling expenses (which I know in the case of one official only is not at all unfrequently never refunded); therefore, these suggestions of extra arbitrators are at the first committee meeting usually thrown to the wind *in toto*, as "extra pull-backs."

To take notes on the spot as to the relative excellence of rival pens in large classes, coupled with time restricted, is impossible, and still more so to record simply from memory the varied characteristics of pen after pen of individual fowls in keen competition. My honest conviction is this, that many buyers of prize pens of poultry have to date their disappointment from one or other of two causes, either "claiming" without seeing the actual prize pens at certain shows, where, to the disgust of the arbitrator, he was compelled to give the prizes to the best birds there to keep faith with the exhibitors, as the committees express it, though very, very imperfect specimens indeed; or through the still more reprehensible practice of sending the money for them, as priced in the catalogue, after the birds were returned to the exhibitor and the show concluded. In the last-named case, oh! how often, in spite of my expostulations, as being no part of the legitimate duty to be expected from a poultry judge, have I been an involuntary witness to the most lively "change-ringing."

My concluding advice to buyers is this—If you want certain pens, examine them on the spot; if approved, claim them at once, and let them go directly through the committee, at the close of the show, to your own address.—EDWARD HEWITT.

WHITE DORKINGS.

It may be useful for poultry-fanciers who have given their attention to any one particular breed, to publish from time to time the results of their experience as a guide to others.

White Dorkings, an exceptionally beautiful variety, provided only they have a clean grass field to run in, have of late been much neglected. Few entries have been made at the principal shows, and consequently the prizes have been reduced in number and value; or the separate class has been abolished, and Whites have been forced to compete at great disadvantages with Coloured and Silver-Grey birds, so different in essential points. I think the breed has fallen into this disrepute from ignorance of its merits; and as my experience in it has drawn me to make a very different estimate of them to that usually given in poultry books, it may not be amiss to relate it.

1. As to their hardihood. It is stated in nearly all poultry books that White Dorkings are a delicate variety. I believe this idea arose from the old notion (an erroneous one, *me judice*), that all white birds are delicate. The earlier authors gave this as their opinion, and others have simply copied their remarks upon breeds in which they are not themselves learned. This I have found to be the greatest mistake. I seldom lose a chicken or have a sick bird. Early in the spring of this year, when, from some mysterious epidemic, I lost the whole of my young stock of Coloured and Silver-Grey Dorkings and Game Bantams, and even many Brahmas and Scotch Greys, of White Dorkings under the same hens I did not lose 1 in 8, and the earlier pullets have long been fine mature-looking hens. The breeding stock keep healthy through the year in a very small run, with two or three hours' exercise daily in a grass field, and rather more liberty at moulting time.

2. As to their laying properties. They are generally classed with other Dorkings as bad layers. This, too, in my yard has been proved an entire error. The pullets begin to lay at six or seven months old, produce more than twice as many eggs—large round ones of a pinkish colour—as Coloured or Silver-Grey birds, and often continue to lay through nine months in the year. They are almost non-sitters. Some steal their nests, hatch in a wood, and prove good mothers; but they hardly ever take to the nest in a house. I have hens of two years and a half old, which have never shown the slightest desire to sit.

3. As to size. Here they confessedly fall short of Coloured birds; yet last year I had cockerels weighing over 8 lbs. and pullets 5½ lbs. at seven months old. I do not think, however, that mature birds much exceed these weights, at least mine do not; but I believe there are other strains finer in mere size.

4. Their excellence for the table all allow.

Such is my experience. My stock originally came from a farm in Sussex, but it has been necessary to introduce fresh blood through a Birmingham prize cock, and the pullets from this cross lay smaller and whiter eggs. I may be peculiarly fortunate in this strain, but at least it is worth while letting others know that a breed ornamental beyond almost all others with their snowy plumage and coral-like combs, may also be made one of the most generally useful.—O. E. CRESSWELL.

POUTER PROSPECTS.

A most unfortunate fatality has brought into the space of seventeen days the three great Pouter Shows of the season—namely, the Scottish, the Birmingham, and the London; but none the less there are prospects of a competition keener and more advanced than ever.

Glasgow this year, in courtesy to a newly-formed Society, gives place to Edinburgh, at which latter city the great Scottish Exhibition will be held. The new Society maintains that amplitude of schedule in favour of standard birds so long in vogue at Glasgow, but with much judgment has provided two classes only for outside varieties—Mealies, Splashes, &c., hitherto, by a too profuse classification, placed almost on a par with birds of standard pretensions. This arrangement is a clear step in advance, and if persevered in will unfailingly promote the best interests of the Pouter and its admirers. The special prize instituted some years ago by Mr. Volkman for excellence of proportion and carriage, open to all the Pied classes, is transferred to Edinburgh, Mr. Ure keeping that gentleman company by offering a similar prize, so that both cocks and hens may have the benefit of an extra searching adjudication.

Birmingham also maintains its lately-enlarged classification, a proof that a correct principle will surely win its way. Yellow Pied Pouters, however, occupy a most equivocal position, being exiled to the "Any other colour" class, to keep company with Grizzles and Sandies. Whether this is intended as a degradation of Yellow Pieds (sometime the favourite colour), or the elevation of Pouter weeds to the level of standard birds, it is impossible to divine. The judges, however, should have something very trenchant to say in the matter, and by unflinchingly giving all the awards in this class to the standard Yellows, should relegate the weeds to their true position.

London creates astonishment by the energy it is displaying on behalf of a variety it has so long neglected. Hitherto Carriers and Almonds have all but monopolised its attention; but now, as though with a twinge of conscience, it is clearly setting about making up for lost time, and is endeavouring to win its way into favour by an almost lavish consideration of Pouter claims. Of the seventeen cups for Pigeons, four are devoted to Pouters alone. The classification is admirable, compact yet ample; and the prizes are so distributed as to secure the utmost respect for standard excellence. Fourteen classes now take the place of the six of last year, a result mainly brought about by a twenty-guinea fund inaugurated by Mr. Volkman, who, in addition to English donations, has received the heartiest support from Scotch friends and fanciers—a courtesy, we trust, foreshadowing more and more of mutual co-operation. The fund in question is supplemented by £30 from the Show Committee, and a five-guinea piece of plate from Mr. Ord. With a schedule so well constructed and furnished, it will be the fault and the loss of the fanciers themselves, both Scotch and English, should this opportunity be wasted of reviving the Pouter interest and widely extending the circle of his patrons. We hope, therefore, that the nave of the Crystal Palace, where the Pigeons will have the great advantage of being shown, will present a grand gathering of the best specimens from all points of the compass.

Pouters are clearly "looking up," not merely in the better provision which is being made for them, but in that more intelligent regard for a standard undivided and complete, so lately advocated in these columns.

CRYSTAL PALACE POULTRY SHOW.—H. S. Fraser, Esq., Headley, near Liphook, Hants, has sent us the following list

of subscriptions to the cup for Hondane at the great London Poultry Show:—

	£	s.	d.
The Committee of the London Poultry Show.....	2	0	0
Mrs. McAdam.....	0	10	0
The Rev. C. Rowland.....	0	2	6
The Rev. S. Milner.....	0	3	6
Mr. W. Massey.....	0	10	0
Mr. R. B. Wood.....	0	10	0
Mr. W. Dring.....	0	7	6
Mr. W. O. Quibell.....	0	5	0
Mr. H. S. Fraser.....	0	12	6
Total.....	£5	0	0

We are requested to state that the Committee, through the donations of a few amateurs per Mr. G. Saunders Sainsbury, are able to offer four prizes of £3, £1 10s., £1, and 10s for Black Ducks. Also, that exhibitors wishing to send their birds to other shows will be allowed to remove them after 6 P.M. on Saturday, December 10th; or they will be dispatched, if the proper labels are sent, on that evening; but in all cases a written request should be made to the Honorary Secretaries not later than Wednesday, December 7th.

INQUIRY.

I BEG to offer the following in explanation and defence:—In the first place I would remark, that there is something very strange and highly suspicious in any man advertising wares under a false name, and that George W. Pardon, shoemaker, Driffield, writing under the incognito of "J. Punshon," furnishes *prima facie* evidence that there must be something radically wrong. The object of the writer of this is not to recriminate or attempt to depreciate the much-vaunted 150 head of prize fowls of "J. Punshon," but "I will a plain unvarnished tale deliver," by giving the real facts of the case.

Attracted by an advertisement of 150 head of prize fowls for sale by a "J. Punshon, of Downe Street, Driffield," a gentleman took train to Driffield in quest of the said J. Punshon, of Downe Street, but after a long search no "J. Punshon" could be discovered; the object of search was voted a myth, the gentleman feeling very foolish and chagrined. "East Yorkshire," it appears, was about to leave by train, and casually entering into conversation with one of the railway porters, was recommended to apply to me as an extensive exhibitor. The gentleman came, or rather was brought to me, and I had the pleasure of selling him a pen of first-rate birds, and not "second-rate," as stated by J. Punshon. After the sale of the birds the gentleman naturally conversed on the subject, and most assuredly I mentioned the fact of J. Punshon's fowls being diseased, but not with the remotest intent of affecting J. Punshon's interest; indeed, the facts of the birds having been purchased and the gentleman being about to leave, showed there was no such animus.

In conclusion I would remark, that I can well afford to allow J. Punshon his bragat remarks relative to the number and quality of his fowls, and, perhaps, he will pardon something like the same principle in myself, when I remind him that during the last three seasons I have taken 450 prizes, and have sold single birds for as high as £3 10s. each.—GEORGE HOLMES, *Laura Cottages, Great Driffield.*

[Here this correspondence must cease from our columns.—Eds.]

RABBITS AT THE COMING YORK SHOW.

THE Committee are congratulated on the attractive prize list—viz., two five-guinea cups for five classes of Lops; one silver medal, value one guinea, for the "Variety classes"—viz., Angora, Himalayan, and Any other variety. The first five classes are for single Rabbits, the last three are for pairs. Entrance fee, 2s. in all classes. Prizes—20s. and 10s. classes 1 to 5; 15s. and 7s. 6d. classes 6 to 8.

I cannot think, with the above facts before me, that "CUNICULUS" can congratulate the Committee on offering such unfair terms to the latter three classes, well knowing the variety classes will be about two to one at the Show. I was canvassed to contribute towards the cups; I promised 10s. 6d., and pledged to enter eight pens (16s) in the "Variety class" not being a Lop-fancier, on condition that a cup should be given to "Variety classes," and single Rabbits to be a pen, not pairs. My offer was declined, and I was well enabled, and told to collect

for a cup in my own classes, as the cups were for Lops. Can the York Committee, by offering such terms, be dealing fairly with the Rabbit-fanciers? Eleven guineas are collected for cups and medal. I think the Committee ought to have made a common fund, and given three four-guinea cups, which would have been more satisfactory. I shall decline entering anything under the circumstances.—S. G. HUDSON.

The glowing account given by "CUNICULUS" of the above Show, would lead most people to believe that something extraordinary and above the average mark was offered; but now that the subject is fully broached, I have no hesitation in making a few remarks on the partial way in which the prizes, especially the cups, are offered. In the first place, there are five classes for Lop-eared—first prize, £1; second, 10s.; and two silver cups, valued at five-guineas each; entrance, 2s. per pen. Now we come to the ill-used fancy varieties, of which about six have to be content with only three classes, and the prizes as follows:—First, 15s.; second, 10s.; and silver medal for the best in the three classes; entrance, 2s. per pen—just the same as the Lops, to which three times the amount of prizes are given, and but for the generous donor of the medal I suppose we should have to be content with the money prizes alone. Above all other faults is having to show in pairs, which is a great drawback to all exhibitors, besides being very disgusting, and double the weight in carriage. Very often after a show of this kind, you find your finest Rabbit breeding, which spoils her for some time; it is of this that I am loudest in my complaints, and I am sure it is not too late for the Committee, if they think proper, to publish in "our Journal" that they have resolved to have only single Rabbits shown, instead of the pairs. I for one would make double the number of entries to what I should if the list remain as it is, as I do not wish to spoil my prize does for the rest of the coming shows. It is the greatest bar to the success of the York Show, and will keep back some choice specimens. I think if the Judge's name could be stated, we should know better what to send.—J. B.

SOUTHAMPTON POULTRY SHOW.

THIS Show, which opened on the 1st inst., consists of 848 pens of poultry, Pigeons, Canaries, British and foreign birds. It is a very good collection, and although the first was the half-crown day, it was thronged with high-class visitors. As a whole the condition of the birds is excellent. The prize Canaries are superb in colour. We shall publish a full report next week.

- SPANISH**—1 and Cup, best pen in Show, H. Yardley, Birmingham. 2, Nicholls and Howard. *hc.* J. E. Rodbar; H. Brown.

Hewitt, Birmingham. *Pigeons*: Mr. F. Esquilart, London.

[We have not received the prize list of the Canaries; we will publish it next week.—Eds.]

MIDDLESBROUGH BIRD SHOW.

The Middlesbrough and North Riding of Yorkshire Ornithological Association's attractive schedule brought together, on October 28th and 29th, 262 birds for competition—birds, too, of the highest quality—from very distant parts of England; Derbyshire, Northampton, and Bristol sending representatives. Although the birds from the latter place arrived, still they were not in time to be judged, the return having been given in before they could be unpacked and staged. This is much to be regretted. A telegram stating they were sent off was received, and judging delayed to the very latest hour in consequence. First, second, and third prizes, accompanied with a commendation, were awarded in each class, but a great many fine specimens had to put up with a blank.

The Belgians were excellent, those shown by Mr. Needler, of Hull, having many points: the Norwich, especially from Northampton, first-class; and the Lizards, Silvers in particular, Cinnamons, Crested, Yorkshire, Copy, and Goldfinch, Linnets, and Canary Males, all being in good condition for the fanciers' just appreciation. In many classes the competition was very severe, but every attention was paid in discriminating and summing-up these birds which took the highest honours. Mr. Hawman, of Middlesbrough, has reason to be proud of his Even-marked Yellow Norwich, the quality of which is good, and will tell well throughout the season. A better class of "Copy Crests," or "Manchester Copyss," than that shown is not often seen. Every bird deserved a prize. The Crested Norwich birds were indeed real crested specimens, being heavy and even, and well backed-up in quality and plumage. One exception may be here noticed, not with respect to its crest, which is all that could be wished for, but because it departs from Norwich form, partaking of too much the appearance of half-bred Copy. The Clear Green Canary class contained specimens, excepting in two or three instances, the reverse of green. The first-prize bird ran away from all others. In the British bird classes there were several beautiful specimens, conspicuous above others being Mr. J. N. Harrison's fine Brown Linnets, and Messrs. Fryer & McCune's Blackbird, besides many Goldfinches. The Linnets and Canary Males were extraordinarily good and very valuable. The following is the list of the prizetakers:—

BELGIANS.—*Clear Yellow*.—1, W. Needler, Hull. 2, J. N. Harrison, Belper. 3, J. Barrett, Thirsk. c, E. Robson, Middlesbrough. *Clear Buff*.—1, G. Tomlinson, Stockton. 2, J. Barrett. 3, J. N. Harrison. c, L. Belk, Dewsbury. *Ticked*.—1, P. H. Jones. 2, and c, W. Needler. 3, J. N. Harrison. *NORWICH*.—*Clear Yellow*.—1 and 2, Moore & Wynne, Northampton. 3, T. Irons, Northampton. c, R. Simpson, Whitby. *Clear Buff*.—1, 2, and 3, Moore and Wynne. c, R. Hawman, Middlesbrough. *Evenly-marked Yellow*.—1, R. Hawman. 2 and 3, Moore & Wynne. c, E. Mills, Sunderland. *Evenly-marked Buff*.—1, S. Tomes, Northampton. 2 and 3, Moore & Wynne. c, E. Mills. *Unevenly-marked Yellow*.—1 and 3, Moore & Wynne. 2, R. Hawman. c, R. Robson. *Unevenly-marked Buff*.—1 and 3, Moore & Wynne. 2, R. Hawman. c, J. Fawcett. *Crested*.—1, R. Hawman. 2, T. Irons. 3, Moore & Wynne. *COPY CHEST*.—1, Fairclough & Howe, Middlesbrough. 2, W. Hutton, Baildon. 3 and c, W. Cotton, Middlesbrough. *LIZARDS*.—*Golden-spangled*.—1 and 3, J. Taylor, Middlesbrough. 2, E. Mills, c, Stevens & Burton, Middlesbrough. *Silver-spangled*.—1, J. Baines, York. 2, R. Ritchie, Darlington. 3, Stevens & Burton. c, L. Belk. *Broken Cap*.—1, T. Ritchie. 2, J. Taylor. 3, Stevens & Burton. c, F. Armstrong, Belper. *CINNAMON*.—*Jonque*.—1, S. Tomes. 2, and 3, T. Irons. c, E. Mills. *Buff*.—1, T. Irons. 2, Moore & Wynne. 3, S. Tomes. c, G. Tomlinson, Stockton. *Variogated*.—1, S. Tomes. 2, P. Rawley, Bradford. 3, R. Hawman. c, Stevens & Burton. *YORKSHIRE*.—*Clear Yellow*.—1, L. Belk. 2, J. Vail, Middlesbrough. 3 and c, J. Rowlands. *Clear Buff*.—1, J. Fawcett. 2, W. Hutton. 3, R. Cooper, Middlesbrough. c, Fairclough & Howe. *Evenly-marked Yellow*.—1, J. Lees, Middlesbrough. 2, A. Webster, King's Hall. 3 and c, Stevens & Burton. *Evenly-marked Buff*.—1 and 3, Stevens & Burton. 2, J. Taylor. c, Tenniswood and Brown, Middlesbrough. *Unevenly-marked*.—1, L. Belk. 2, J. SHOW OF THE DERBY CANARY AND ORNITHOLOGICAL SOCIETY.

The thirteenth annual exhibition in connection with this Society took place in the Athenæum Room, on Saturday, October 22nd. The Show was the best that has been held, one of its features being the presence of a greater number of foreign birds than usual. Parrots, Love Birds, Australian Magpies, Black-throat Finches, Red Finch, Diamond Sparrows, Chestnut Finch, Zebra Finches, a live Opossum, a case of Iguana Lizards, cases of stuffed birds, an Australian Parrot, Linnæus Mule, Goldfinch Mule, a Thrush, &c., were exhibited, but not for prizes.

A subscription sterling silver cup was awarded to the winner of most prizes in six classes of Norwich birds—Mr. Barnesby had fourteen points, Mr. Henson and Mr. Woodward, Spondee, each gaining eleven points. Six extra special prizes were awarded to the first three winners in each class of the "Spotted or Cross-bred" birds, besides the money prizes of the Society. The winners were Messrs. Haynes, Henson, Barker, Woodward, and Coke. Two other special prizes were awarded, one being for the most prizes in several classes, and the other to the amateur exhibitor who took the greatest number of prizes; Messrs. Barnesby and Clarke being the winners. There were about 150 cages of Canaries and males shown for prizes.

Mr. T. Irons, of Northampton, and Mr. W. Matthews, of Nottingham, awarded the prizes as follows:—

CANARIES HATCHED IN 1870.

PIGEONS ON THE NILE.—Mr. McGregor observes in noting the progress of his canoe on the Nile, "There is one of the Pigeon villages—it exists for Pigeons. A hundred mud towers, about 30 feet high, are clustered together, and myriads of blue and white Pigeons wheel in the air; sometimes passing these in my little vessel, one could see what I had remarked before on the Nile, that, when the banks are steep, and the Pigeons cannot well stand on them to drink, they settle on the water itself, and closing their wings and floating for a few seconds, they manage thus to slake their thirst."—(The Rob-Roy on the Jordan.)

ARE ABNORMALLY EARLY SWARMS DESIRABLE?

The great desideratum with many bee-keepers is to have swarms at the earliest period possible. To accomplish this object they have recourse to various devices. Some encase their hives with haybands, and others have stoves fitted up in their bee houses, but perhaps the plan most generally adopted is that of liberal feeding early in spring. These artifices, no doubt, sometimes succeed in bringing about the end desired, but cases are not wanting to show that on several occasions

they have signally failed, and no wonder; for if the season happens to be cold or wet, or both, the bees that have been prematurely sroused into a state of activity must necessarily go out of their habitation for an airing, and in consequence, great numbers, being unable to return, will perish. A bee coming from a greatly heated atmosphere into the open air, where the temperature is many degrees lower, is very easily chilled, and, if it should be able to find its way back to its dwelling, injurious results to it may follow from the sudden transitions through which it has passed.

Granting, however, that all goes on well, is it desirable to possess a swarm before what is considered the honey-gathering season has set in? If the flowers are few in number it cannot store up much food, or if they are washed much by cold rains it may not even prove self-supporting. Some people, as much distinguished for their ignorance of apian science as for anything else, boast of their superior husbandry when they happen to get a cast a few days or weeks earlier than their neighbours. They think it a great thing to have a swarm before the 1st of June, and that the old adage, irrespective of place and weather, holds good, "a swarm in May is worth a stack of hay;" but excepting on rare occasions, when seasons were unusually forward, I have never found very early swarms prove of much value. When summer is somewhat advanced they are apt to throw virgin swarms which do little good, and then in autumn, when the bee-master wishes to take their honey, he finds that a large proportion has been consumed by brood, and that the combs are anything but beautiful. These remarks apply chiefly to those who follow the system of their forefathers, and use only straw hives. But whatever be the material or form of hive employed, I do not think much benefit can accrue from the possession of too early casts. The date at which we should endeavour to have them cannot be fixed; this depends upon both the locality and the season, and it may happen to be either in May, June, or July.

For my part I never wish to see a swarm on the wing until the clover is coming into full flower, and the temperature rises to 62° or above it. In the district where I reside this happens to be generally about the end of June or beginning of July. The greatest produce during the last twenty years has been yielded by swarms that came off in July. Several of my neighbours this year had casts about the beginning of June, but the best of them had scarcely an ounce of honey stored up on the 15th of July. The weather was most unfavourable, and vast numbers of these tenants of empty houses perished from sheer starvation. With their numbers half diminished they began the labour of true honey-gathering on the 17th, but none of them prospered so well as swarms that did not emanate till about the 20th.

To prevent several of my stocks from swarming in June I gave them additional room, and supplied them with just as much food as was needed to save them from dying of hunger. When any young drones were ejected I knew it to be a signal of their supplies becoming exhausted, and forthwith they were furnished with from half a pound to a pound of either honey or syrup. When, therefore, summer proper and the honey season commenced, about the 17th of July, these stocks were all vigorous, and a few days afterwards were able to throw large swarms. These casts enjoying fine weather, and finding the fields covered with clover, filled their habitations completely in less than a month, and I need not add that their combs, only a small portion of them having been used for brood, presented a very attractive appearance. I do not, then, think that it is wise to have stocks more forward than the season, or to hasten swarming before the clover has come into flower and the weather promises to be favourable. It may be different in other localities. I speak only with reference to my own, where, on an average of years, it is sufficiently early to have swarms by the 20th of June.—R. S.

OUR LETTER BOX.

PLYMOUTH POULTRY SHOW—We were wrongly informed that Mr. Hewitt is to be the Judge at this Exhibition. He was applied to, but had a previous engagement.

WEIGHT OF LIGHT BRAHMA AND WHITE COCHIN PULLETS FOR EXHIBITION (Cheltenham)—You must have patience. Your pullets have not done growing because they have begun to lay. When this inflection, which many would pardon, is over, and its successor a little broodiness comes, your pullets will furnish and put on weight. Up to six months, if they are to be expected to take a prize, your chickens should weigh a pound for each month, Brahmas rather heavier than White Cochins. You will obtain weight by persevering. In all probability you already have the necessary scaffolding. Filling is easy work. Good ground oats mixed

with milk, table scraps, a little maize twice per week, an occasional lettuce, and any other gastronomic attention you can pay, will produce weight.

SILVER-SPANGLED HAMBURGERS' EARLOCKS (Idem).—We fear the red earlobe of the Silver-spangled Hamburga is hereditary. Good birds sometimes have the earlobe red during the moulting season, and some never have it white till they are twelve months old.

BREEDING PENCILLED HAMBURGERS (W. S. D. C.).—We believe you may safely breed from the cocks you name. Pencilled tails are always accompanied by pencilled hackles. Cock chickens are always pencilled when young, and as they lose the chicken feathers the pencilling disappears. To obtain the rich deep colour you want you must choose hens that are very much the colour of the shining top of gingerbread. These are always very heavily pencilled, and they will give you the colours you want in both sexes. It is almost impossible to breed exhibition cocks and pullets from the same parents. A good cock should not be light-coloured. His tail should be black, edged with rich bronze, but only edged. Never breed from a cock with a faint, washed-out hackle (we have seen them almost yellow), nor from mossy nor poorly-spangled hens. No amount of pedigree would induce us to breed from a defective bird.

DORKING CHICKENS WEAK-LEGGED (Constant Reader).—Your fowls have outgrown their strength, and their bodies are too heavy for their legs. That is why they rest on their knees. They are at the gawky age. They will never be better to eat than they are now if they are in good flesh, but often when they make so much growth they do not put on flesh. If they have flesh, you may either kill and eat them at once, or you may shut them up in a place where exercise is impossible, and feed them three times per day on ground oats and milk until they have fattened. There is nothing in the weakness to make them unfit for food, but we should not advise such for stock.

GAME BANTAMS NOT HATCHING TRUE TO COLOUR—COLOUR OF DUCKLING AND BROWN RED GAME BANTAMS (H. J. H.).—There can be no doubt the eggs have been mixed, or another cock has had access to the hen, or more likely still, the egg has thrown back to some other strain which has been used in making the birds. The description you give of the chicken is exactly that of a File. It is, therefore, likely some of that breed exists in your birds; you need not be surprised, as a strain will lie ignored for many years, and then suddenly show itself in force. The ordinary Duckwing's breast should be salmon-coloured, the hackles striped, and the back and body grey. The hen of a Brown Red should be nearly black with a golden-striped hackle. We should not pronounce hastily on the birds.

BLACK ROSE-COMBED BANTAMS WITH PALE COMBS (DeLa).—The combs will become redder as the season goes on and as the birds get older, provided they be kept in condition. It will be the same with the earlobes. Give them some cooked meat and some hard-boiled eggs chopped fine.

BRAHMS' LEGS DISEASED (T. F. A.).—The disorder of which you complain, and which has been called "poultry elephantiasis," is of recent introduction, and is, we believe, incurable. It does not of necessity belong to the Cochins, although they are most subject to it. If we owe it to them, it was many years in showing itself, and must be the result of interbreeding and consequent disease. We do not believe it to be hereditary. We have only succeeded in some instances in treating it successfully. It was in the early stage, and we kept the legs constantly moist with compound sulphur ointment. Lettices that have gone to seed are good food for fowls in this state. We have this disorder in Brahmas, Cochins, Crève-Coeurs, and Pheasants. It is very common for the centre toe of a Brahma cock to be crooked, and it is not very important that it should be scantily feathered. The feathering is on the leg, that is essential. Neither of the defects or shortcomings you mention should discourage you from exhibiting.

DORKING COCK'S FOOT SWELLED (Michael Dorking).—If the swelling on the cock's foot is hard enough to bear cutting, cut it by all means, but you should not make it bleed. Nothing is so difficult of cure as a sore on the foot of a Dorking cock, on account of the weight of the bird. We have known iodine beneficially used, but while it is applied the foot must be kept wrapped up. We should think the hen is kept too fat.

CHICKENS CROP-BOUND (F. T.).—There is no doubt of the healthiness of your chickens; they have grown up in spite of your feeding, and not because of it. We cannot imagine anything worse. Your fowls are suffering from being crop-bound. That generally arises from food. Flour (not meal) mixed close will clog a crop. Dry grass eaten from the lack of green meat will form a ball in the crop (like the "casting" of a deer), and in either case the bird will be crop-bound. The treatment of the disorder is twofold: First pour hot (not boiling) water down the throat and most gently manipulates the crop till the hard mass becomes soft and impressionable. Then continue the hot water till the crop is relieved, either by vomiting or otherwise emptying the crop. After the softening of the crop, give two table-spoonfuls of castor oil. When this has been taken, feed for some days on oatmeal mixed almost liquid, and ascertain by feeling that the crop is emptied after every meal. If this fails the only resource is to open the crop and take out the contents. It is an easy process. Pick off the feathers in a straight line down the breast, measuring from the head. With the thumb and finger squeeze the obnoxious body to the front till the bare skin protrudes, cut it straight with a lancet or sharp knife till the contents of the crop come out. Then have a very soft sponge and a glass syringe at hand, send some warm water down from the crop to the gizzard, and then with plenty of water thoroughly wash out the crop. To use your own words, it will "stink fearfully." When this part of the operation is over, take a stout needle threaded with coarse thread well covered with grease. Recollect you have to sew up the crop first, and afterwards the skin. If you get nervous or tired of the job you will probably sew-up skin and crop together, and the bird will die. To open the crop sufficiently will not require an opening of more than 2 inches in length. Five sutures will be sufficient; these should be thoroughly saturated with grease, and the lips of the wound should be brought close together. Then the skin should be sewed the same. The bird, fed during a week on gruel, and another week on slack meal, will at the end of a fortnight know nothing of the operation. Where such cases occur often the feeding is at fault.

GAME MOULTING WITH DIFFICULTY (A. H. H.).—There is something

WRONG IN YOUR FEEDING, or in the locality in which your fowls are kept. No fowl can moult with a heated body, as the feathers lack moisture; they itch, and the birds pick them out. We do not think linned good, as it has a tendency to make soft feathers. We advise you to feed on ground oats mixed with milk, a little chopped cooked meat, and now and then a little Indian corn, all preceded by purging with castor oil—dose, one table-spoonful.

HAMBROGH'S COMB AND LEGS SWOLLEN (M. M.).—Purge your birds freely, and use Bailey's pills.

BRAHMAS' COMBS (A. B. C.).—The single comb of a Brahma cock does not disqualify. The loss of an eye to a Spanish cock is a great disadvantage, but it does not disqualify.

FOWLS FOR AUTUMN AND WINTER LAYING (Hampshire Highlander).—Brahma Footras, Cochins, or Crève-Coeurs will suit you; the latter do not sit. Winter laying depends more on the age than the breed of the bird. Only pullets can be relied upon to lay during the winter.

EXHIBITING HENS (G. M. A.).—The feather is neither red nor inclining to red, and is quite unimportant. You may safely put your two hens together. Exhibiting hens of different ages in the same pen is commonly done, and is often necessary. It is not fair to show a hen and a pullet for two hens. There are but two classes, and they consist of hens and pullets. No one inquires, and very few can tell the age of the former.

ARTIFICIAL FOODS (C. E. M.).—We have so strong a conviction about these that we cannot insert any communications about them.

MANURE HEAP IN FOWL AND PIGEON ADOBE (Alpha).—We are not in the least surprised that your birds have died when they roost over a manure heap; nothing could be worse than an atmosphere charged with exhalations from decomposing matter. Carriers are, says Mr. Brent, "excellent breeders and nurses if not allowed to be too fat." They are, for high-class birds, strong and robust.

FOOD FOR DOVES (Vincent King).—Collared Turtle Doves, commonly called Ring Doves, are best fed on wheat, canary seed, and rarely hemp seed. In cooing, the cock's note is deep and mellow, and he swells his throat, then, rising and taking a step forward or after his mate, he repeats the same gesture and voice. The "Pigeon Book," by Brent, to be had from our office for twenty stamps, contains a good article on these birds, and the full particulars you require.

SICK POUTER (David Laurie).—We do not see that you can do anything more for your bird than what you are doing and intend to do.

WING DISEASE IN CARRIER (C. H. C.).—Dress the part with tincture of iodine; a druggist will tell you the strength of what you buy of him, and how often to use it, as the strength varies. The cause is scrofula. If the wing becomes stiff he will be useless to breed from, but in a hen it does not matter. Scrofulous birds are very apt to produce young like themselves, but it is not a contagious disease.

CARRIERS' EYES (Henry Cockton).—Try first a weak solution of alum and water applied twice a day; then, if that fails, a lotion of lunar caustic used carefully. If the trouble comes from the formation of spouts—that is, by the turning out of the lower lid, cut them off from below with a pair of very sharp scissors.

PIGEONS LEAVING THEIR COT (W. L. D.).—In or near their cot put some "salt-cat;" it is composed of about equal quantities of clay, such as brickmakers use; a coarse, gritty sand, or fine gravel, in which the grains are about the size of peas' heads; and old mortar: to this is added a small quantity of baysalt. Some persons, to make it more attractive, add aromatic seeds—such as cummin, anise, coriander, and caraway. The whole should be mixed up, with chamber-ley, into the consistency of mortar, and placed in a crock, the sides of which are perforated with many holes, large enough to admit the Pigeons' heads, and covered with a lid to keep off the weather.

PIGEONS (T. C. F.).—"The Pigeon Book," by Brent. It can be had free by post from our office if you enclose twenty postage stamps with your address.

PARROT, FEATHER-EATING (A. B. C.).—Feed on fruits and bread and milk, no meat, and give a shower bath of tepid water daily through the rose of a watering-pot.

FEEDING BEES (A Notice).—The best mode of feeding is by means of an inverted bottle, the mouth of which must be tied over with a bit of

course lens or cap-net. With common hives the bottle-neck may be inserted in the central aperture, which usually exists (if not, one should be made with a sharp pen-knife) in the top, and refilled as often as may be necessary. With flat-topped hives the bottle should be supported by its neck being fitted into a perforated block of wood about 5 inches in diameter, and it will be found convenient to interpose a piece of perforated zinc, to prevent the bees escaping when the bottle is refilled.

BULLFINCH'S FOOT SWOLLEN (Lady C.).—Many cage birds are subject to diseases of the feet, arising, for the most part, from their perches, &c., not being kept scrupulously clean. In this case, however, cleanliness seems to have formed a prominent part of the régime, and the cause of the disease must be looked for elsewhere—possibly in the disordered state of the system consequent upon, or incident to, the struggle the bird has had in moulting. I can advise no better treatment than bathing the foot in warm water; and if the second swelling or gathering should assume the character of the first, prick it also, though I am adverse to performing surgical operations. Give a little hempeed.—W. A. BLAKSTON.

MULBERRIES, WHAT TO DO WITH THEM (Alice C.).—You can do as follows:—*To Preserve.*—Put the fruit into a preserving-pan, add draw from it, over the fire, a pint of juice. Take 3 lbs. of pound-d sugar, wet it with the juice, then boil it up, skim it, and put in 2 lbs. of ripe mulberries; let them stand in the syrup till warm through, and then set them on the fire to boil gently. When half done put them by in the syrup till next day, then boil them as before, and when the syrup is thick, and will stand in round drops on becoming cold, they may be put into pots for use. *Mulberry Pudding.*—Make a paste of 1 lb. of flour, 4 ozs. of beef suet chopped very fine, and hot water, with a little salt. Roll it out upon a board, then line with it a basin, which fill with very ripe mulberries; cover with paste, tie the whole tightly in a pudding cloth, plunge it in boiling water, and let it boil an hour or two according to its size. *Mulberry Wine.*—Take mulberries when they are just changed from their redness to shiny black; gather them on a dry day when the sun has taken off the dew, spread them thinly on a fine cloth on a floor or table for twenty-four hours, and boil up a gallon of water to each gallon of juice. Skim the water well, and add a little cinnamon slightly bruised. Put to every gallon 8 ozs. of white sugar candy finely beaten. Skim and strain the water when it is taken off and settled, put to it the juice of the mulberries, and to every gallon of the mixture put a pint of white or Rheims wine. Let the whole stand five or six days in a cask to settle, then draw off the wine, and keep it cool. This is a very rich cordial.

DAMP WALLS (A Cottage Gardener).—Paper them with waterproof paper before putting on the usual paper.

METEOROLOGICAL OBSERVATIONS

From observations taken near London during the last forty three years, the average day temperature of the week is 43.6, and its night temperature 34.1. The greatest heat was 63, on the 12th, 1841; and the lowest cold 18, on the 15th, 1865. The greatest fall of rain was 1.24 inch.

IN THE ROYAL FRUIT ROOMS.

RIGHT royally for many years have fruits been grown in Frogmore Gardens, and it is meet that it should be so. We look to Royalty herself as our ruler, our guide, and our example. We look to the Royal gardens and gardeners of Frogmore in like manner to show us much that is great and good, and all that is possible to be done in gardening. The sphere of gardeners at Frogmore is amongst fruits and vegetables—to supply the Royal household, and it is done well. To vegetables I will not here refer, further than to observe that in no other garden in England have I seen a more regal supply, and in such enormous quantities. There is vegetable-growing in earnest. But to the fruits.

I will here again pass by the long and noble ranges of vineries and pineries, with such Pines as Frogmore alone produces, which I will notice afterwards. I pass by the Peaches under glass and on walls, the Plums, Cherries, &c., and on to the Royal fruit rooms—to the Apples and Pears. Here, being joined by Mr. Powell, who has for many years so worthily had the charge of this department, first under Mr. Ingram, the founder of the gardens, now under Mr. Rose, his worthy successor, I was soon absorbed in a world of fruit. My visit was paid on the 26th of the past month, rather late in the season for many of the fine Pears; the glut of ripening Pears had just passed over, and a more steady succession was coming in. All were gathered, and here was the Royal supply for the months of the coming winter.

The fruit rooms at Frogmore are two in number. One is a large, lofty, square room at the back of the long range of vineries near to Mr. Rose's house, well fitted-up with shelves round the sides, and having a long centre table with drawers. The shelves are plain deal, on this paper is placed, and then the fruit. This is a very commodious, light, and airy room, better fitted for showing off the fruit than for keeping it; that being indeed the purpose for which it is principally used. Specimens of the different fruits are selected and placed here nicely ticketed and named for their Royal mistress to behold. I was told the Queen frequently has a peep at them, and it was pleasing to hear of the great and general interest she takes in all these little matters.

Fruit room No. 2 is a long, narrow, lean-to shed, I should say nearly 200 feet by 9 feet, with shelves on each side, and a pathway down the centre. There is nothing ornamental about this room, yet it is wonderfully well adapted, as has been proved, for keeping fruit. There is a door at one end and a small window at the other, whence all the light is derived. It is thus almost pitch dark in the centre at midday; to examine the fruits lamps are always wanted. Darkness is a very material point in regard to the preservation of fruit. The roof is thickly thatched with straw, the walls are thick, and the floor is thickly concreted, so that the room is at once dry and equable in temperature. Enormous quantities of Apples and Pears are stored in this

room, being placed on the shelves—the larger and finer in single layers, the others in heaps from 6 to 12 inches deep. I was struck by the general fine appearance of most of the sorts, which were pretty numerous, especially the Apples, but I was told they were smaller than usual, but richly coloured. Many of the Pears, the old standard sorts, were very fine. I missed, however, from amongst them many sterling sorts of more recent introduction, which I would suggest Mr. Rose should add to the Royal collection. I allude to such as Doyenne du Comice, Josephine de Malines, &c. These should be there in quantity.

Of the Pears which seemed to find most favour here, and which were to be seen in fine order, I may note Marie Louise, the last of which I was just in time to see; they having ripened much earlier than usual this season. We all know the good qualities of this Pear. Chantrelles were here, and are always wonderfully fine, much more round in shape, more hands-ome, and better-looking than when grown near London. There was here an immense quantity of Vicar of Winkfield with its peculiar twisted squinting look. It is very handsome without. This is of poor quality as an eating fruit, but is here found to be the best for stewing, so it is well worthy of cultivation for that purpose. Easter Beurre was here in grand style, and is usually tolerably good for late work. It is, however, considered inferior to Doyenne d'Alencon, a variety which in almost every fruit list is given as a synonym of Easter Beurre. As it is to be seen at Frogmore it is quite distinct. Single specimens of either could not be distinguished the one from the other, perhaps, but in the mass the characteristics are very striking. The flesh of Doyenne d'Alencon is yellow, whereas that of the Easter Beurre is white. Mr. Powell much prefers the former. Beurre Diel was also very fine. What a variable Pear this is! Here also were great shelves of Beurre de Rance, a first class late Pear but this season getting ripe now. Knight's Monarch did not look so well here as usual. This is one which has proved to be of the highest quality at Frogmore, yet is very seldom so elsewhere. It has an ugly habit of falling off the trees before being ripe, and shrivelling up afterwards. Mr. Powell, however, seems to understand its vagaries. Glou Moreau looked particularly well—great, clear yellow fellows—the type of a Beurre I should say. There were quantities of the large Duchesse d'Angouleme, the favourite Pear of the Paris markets, yet no particular favourite of mine. Winter Nelis was in great store, of the usual smallish character, invariably of fine quality. Of the old Swan's Egg, and its off-pring the Frogmore Swan's Egg, there were fine specimens, the latter being of a more rounded form, and fully sweeter than the former. Here also I ran across the old Maccas, a very good sort, and the Sabine, one of Mr. Knight's seedlings, but of no particular merit. Jean de Witte is likewise much approved of. It is like a small rich Glou Moreau. Here is another Pear very much condemned of late—viz., Prince Albert. At Frogmore this is by no means a bad variety. In appearance and quality it resembles the old Colmar. The most showy of all Pears, the Porelle, or Tront, was here in abundance. It is a pity it is not of a little better quality,

being only second-rate. Napoleon seems to be extensively grown, from the great stock of the fruit. What a wonderfully juicy Pear is this! and sometimes of very good quality. I noticed, besides, great quantities of that very ugly Pear Ne Plus Mennis, but a most excellent late spring variety.

To this already numerous list there are many other varieties to add, such as Fondante de Malines, a truly good, useful, little-known sort, very similar to Serrurier d'Automne; Reine d'Hiver, a highly-flavoured variety; Maréchal de la Cour, a splendid sort; the old Crasanne, a much overrated Pear; the Catillac and the huge Uvedale's St. Germain for stewing, of all of which there are remarkably fine examples to be seen. Many of these were grown on walls on fine old trees, models of careful training, chiefly on the fan system, which, in my opinion, is not so well adapted for the Pear as the horizontal. Others were grown on low arched trellises, others on pyramids and open standards. Nearly the whole of these trees in the gardens have been severely root-pruned by Mr. Rose since his advent amongst them, and with the most beneficial results. Trees which for years previously had produced but little fruit were last season, as I was informed, fully laden; the specimens, however, were not so large as from trees not root-pruned. The appearance of the whole of the trees, however, augurs well for an abundant crop next year.

Amongst Apples, although I was told they were unusually small, there were some remarkably fine examples. In general they were highly coloured and consequently very handsome. Blenheim Pippin was in great store. How this Apple varies from a great angular green fruit to a flat, regular, highly-coloured beauty almost resembling a Pear's Pippin! It is perfectly possible to select two Apples from the produce of a single tree so dissimilar in appearance as to defy Dr. Hogg himself to name them. Of King of the Pippins there were many bushels, and it is a very great favourite. This is another very variable Apple. Rosemary Russet was in fine order and in great quantity. This is one of Mr. Powell's favourites. "Give me," said Mr. Powell, "if I were a market gardener, of Apples Rosemary Russet, Scarlet Russet, and Cox's Pomona, and I would grow no other; they are all splendid varieties, and sure croppers." Cox's Pomona is one of the best large soft-fleshed Apples for dessert, and at Frogmore it is grown in quantity. Scarlet Russet is also beautiful and fine. Lord Naglan is rather a new sort, streaked, with a dash of Ribston Pippin flavour. Hampshire Golden Pippin is a good useful sort, and Gipsy King, a seedling, flat dessert Apple, somewhat like Sam Young. Court-Pendu-Plat was very splendid, and no better Apple exists in its season—January. Damsel's Seedling was unusually small. Of all the cooking Apples, perhaps this is the richest and best. Scarlet Nonpareils were very fine, and in great number, also the old Nonpareil; some specimens of this of such an enormous size and so totally different in character were shown me, that I positively refused to believe them to be true; others gathered from the same tree, however, had all the usual appearance. Never have I seen old Nonpareils so fine nor half the size. Frogmore Prolific was here also pointed out to me as one of the best autumn cooking Apples. This is a large sort, with fine white and tender flesh, raised at Frogmore. There are, besides, many other seedling Apples well worthy of cultivation. I observed a large quantity of Cockle Pippin, the favourite Apple of Sussex, and Dutch Mignonne, so justly esteemed for its good keeping qualities; also Golden Harvey, the richest and the best of all the small dessert sorts, and here the examples were good; Adams's Pearmain, than which there are few better; Cox's Orange Pippin, the most useful and prolific of all, and of the finest quality; Grenadier, a rather new, flat, scarlet-coated sort; Small's Admirable, a large and fine kitchen variety; and Small's Imperial, a large, streaked, pretty, highly-coloured sort, not so well known. Besides all these, there are many other fine varieties which I had not time to notice.

In conclusion, I would only add my mite of approbation of the general style of cultivation adopted here, and of the very efficient manner in which the Royal Gardens are conducted under Mr. Rose. I advise all who can to get a peep and judge for themselves. All such will there receive a Highland welcome.—ARCHAMBAUD.

PATERSON'S BOVINA POTATO.

In the spring I purchased 1 lb. of this remarkable Potato at 1s. 6d. per pound. These I cut into seventy-four sets, seven of which I parted with, and four failed to grow. I planted

them deeply, on the 30th of March, in loamy soil, heavily manuring it at the time with stable dung, giving a distance of a yard each way between the sets. When well up I drew a little earth round the roots; beyond this, and keeping the weeds down, they had no attention whatever. On November 2nd, on digging the crop, it was found to produce 7½ bushels, weighing 4 cwt. nett, of very large Potatoes. These facts may interest some of your readers.—ALFRED PEGLER, *Old Shirley, Southampton.*

P.S.—It is right to observe that not a drop of rain fell here during April, and in May we only had rain for two days, whilst in June we had but a couple of thunder showers. With a moderate degree of moisture I believe the crop would have been heavier.

GROUND LEVELLING AND PRACTICAL GARDEN PLOTTING.—No. 4.

DRAWING PLANS.

To Inscribe a Regular Polygon, in this case a pentagon, in a Given Circle.—Fig. 12 is thus described by Mr. Ellis A. Davidson in his work on linear drawing:—"Draw the diameter A B, and divide it into as many equal parts as the polygon is to have sides (in this case five). From a and b, with the radius A B, describe arcs cutting each other in c. From c draw a line, passing through the second division and cutting the circle in d. Draw d b, which will be one side of the polygon, set off the length d b around the circle—viz., e f g, join these points, and thus complete the figure. Any polygon may be thus formed by dividing the diameter into the number of parts corresponding with the sides of the required polygon, but the line c d must in every case be drawn through the second division."

Fig. 12.

Fig. 13.

I have adopted this method in preference to any other, because I think it is easiest understood, and can be applied in the formation of any polygon.

- Polygon, a figure of more than four sides.
- Pentagon, a figure of five sides.
- Hexagon, a figure of six sides (Fig. 13).
- Heptagon, a figure of seven sides.
- Octagon, a figure of eight sides.
- Nonagon, a figure of nine sides.
- Decagon, a figure of ten sides.

For a bed it is not advisable to have a figure of more than eight sides, as such would approach the circle so nearly that it is better to have a circle instead.

Fig. 14.

Fig. 15.

Fig. 14.—To Construct an Equilateral Triangle, A B C.—From A B C, with radius A g, equal to half the side of the triangle, describe arcs d e f.

Fig. 15.—To Construct a Square, A B C D.—With the radius A i, which is half the side of the square, draw arcs e, f, g, h.

Fig. 16.—To Construct the Pentagon, *A B C D E*, as described in fig. 12.—With the radius *Ab*, which is half the side of the pentagon, draw arcs *f, g, h, i, k*.

Fig. 16.

Fig. 17.

Fig. 17 is an application of fig. 13, in the same way as fig. 16 is an application of fig. 12.

A Hexagon may be formed by describing a circle, and applying the radius of the circle six times to the circumference, which will give the sides of the hexagon as nearly as need be.—M. O'DONNELL, Gardener to E. Leeming, Esq., Spring Grove, Richmond.

WINTER-BLOOMING ORCHIDS.—No. 10.

CALANTHE.

THE section of this genus which I here introduce consists of deciduous plants, producing their charming flowers during the winter months. They have been established as a distinct genus (*Prepanthe*), by Professor Reichenbach, a course which I consider correct, and which I adopt myself, but in consequence of very few Orchid growers in this country having adopted it, I have in this place retained the original name. These plants are very ornamental, and as they easily form good specimens and are very reasonable in price, they should be largely grown for winter decoration by everyone having a stove. The objection made to them by some is their deciduous character, and it is still the fact of the flowers being produced when the plants are leafless robs them of half their beauty, which is undeniably an objection, but still one that may be easily remedied by grouping them with such plants as *Dracæas*, *Crotons*, and *Ferns*. Besides the cheerful appearance the flowers of these plants produce during the dull months in the plant house, they are also extremely valuable for cutting either the entire spike for placing in vases in the drawing-room, or the single flowers for bouquet-making. To produce good flowering plants they should be potted in sound fibrous peat, leaf mould, well-decomposed cow manure, and sand in about equal proportions. The pots, be it remembered, should have been previously well drained. This operation should take place about the beginning of March, or earlier if the least sign of growth appears, for as these plants lose roots as well as leaves every season, the old soil will require taking away every spring; hence the necessity of putting them into new soil before the fresh roots start into the worn-out compost of the previous season. During the growing season water liberally, and I have always been most successful with them when I continued giving moderate supplies after the leaves had fallen until the flowering season was over, after which they should be kept quite dry for some time. Some growers of these plants fall into the error of drying them as soon as the leaves begin to decay, a system, however, which I have found very detrimental to the flowers. These *Calanthes* should not be grown in the East Indian house, but amongst the *Cattleyas* or *Odon-toglossums*; when grown in strong heat they are very liable to disease both in the leaves and pseudo-bulbs.

C. VESTITA.—Pseudo-bulbs broadly ovate and obtuse, and silvery grey in colour. The leaves are borne on the apex, and are from 1 to 2 feet in length, membranous, plaited, and broadly lanceolate, tapering to a point. The scape rises from the base of the pseudo-bulb, growing erect for half its length, and then becoming pendulous and producing a profusion of flowers, which continue in full beauty for several months. The sepals and petals are about the same size, spreading, broadly-lanceolate, and sharp-pointed. The lip is spreading, deeply

three-cleft, with a spur at the base, middle lobe cuneated; the lateral ones oblong obtuse. The whole flower is of a pure white, in some forms the sepals and petals are creamy instead of pure white. Native of Burmah.

C. vestita rubro-oculata.—This resembles the preceding in habit of growth, but is, perhaps, somewhat more robust. The flowers are more showy in consequence of their having a large, rich, crimson blotch at the base of the lip. Native of Burmah.

C. vestita flavo-oculata.—An exact counterpart of the previous variety in general appearance, except in regard to the flowers, which are stained at the base of the lip with orange yellow instead of crimson, which produces a beautiful contrast. Native of Burmah.

C. vestita Turnerii.—This is a distinct variety, but I am quite ignorant of its origin. It blooms later than the other forms, and the base of the lip or eye is deep rose colour.

C. VETCHII.—A most lovely winter-blooming plant, for which we have to thank Mr. Dominy, it being one of his hybrids. It is the result of a cross between *Limatodes rosea* and *Calanthe vestita rubro-oculata*. The pseudo-bulbs taper more to a neck than any of the *Calanthes*, and in this respect it resembles *Limatodes*. It is deciduous, and produces long, half-pendulous spikes of rich rose-coloured flowers, with a white eye. The shape of these blooms is longer than in any of the other kinds. It is a superb plant, and one which should be absent from no collection however small.

LIMATODES.

This genus is nearly allied to *Calanthe*, the principal points of distinction being a lip quite detached from the column, not united with it, and in the much longer column. The same treatment as recommended for *Calanthe* also suits this admirably.

L. ROSEA.—The pseudo-bulbs of this plant are fusiform, contracted about the middle, with a narrow neck. The leaves are produced from the apex, and are oblong-lanceolate, smooth, and plaited. Scape erect and proceeding from the base of the pseudo-bulb. Flowers pink or rose saving at the base of the lip, and there they are white; lip larger than the sepals and petals, oblong, flat, and retuse; spur straight and blunt. This very handsome species blooms during midwinter, and continues long in full beauty. Native of Moulmein.

L. rosea vestalis.—A variety of the above, producing pure white flowers. It is very elegant, and a charming contrast to the various shades of rose and pink of the species. Native of Moulmein.

EPIDENDRUM.

As regards this extensive genus I purpose confining my remarks to two species only, and they both well deserve general attention for the ease with which they may be grown, the cool treatment under which they thrive, and the rich and rare colour of their flowers, which are produced during midwinter, and last such a long time in full beauty if ordinary care be taken to keep them from being wetted. There are many other species of *Epidendrum* which bloom at this particular season, but the majority of them are small and unattractive, and, therefore, it is only reasonable that amateurs and gardeners, especially those with limited space, should prefer the most attractive kinds, or those yielding the greatest number of charms.

E. VITELINUM.—The pseudo-bulbs of this elegant species are ovate acuminate, and bear two leaves, which are oblong and acute. The many-flowered raceme is produced from the apex of the bulb and from between the leaves; sepals and petals ovate-lanceolate, acute, and rich orange scarlet in colour. The lip is linear, narrowed below, becoming suddenly acute and bright yellow. This plant is a native of Oalaca, where it grows at elevations of some 3000 feet above the sea level. This fact being known, it is natural to infer that the plant succeeds only in cool places. I have had the greatest success with it treated as a block-plant, using a little moss for the roots to penetrate, by keeping it in the coolest place I could find in the *Odon-toglossum* house, and by never at any season depriving it entirely of water. I have seen a plant in various collections called *E. vitelinum*, but which has caused much disappointment to the possessors when in flower. It is *E. virgatum*, which very much resembles the former plant, but the leaves are more glaucous, and it produces a long spike of small, dirty greenish-brown flowers.

E. HAGUENSE.—The thin stem-like pseudo-bulbs of this plant are furnished with oblong, obtuse, fleshy dark green leaves. The flowers are produced in a terminal cluster, and are orange-scarlet in colour. It is easily grown, dwarf in habit, and an abundant bloomer, qualities which should recommend

it to all. E. ibaguense is a plant of somewhat recent introduction, and may be grown either upon a block or in a pot. If the latter method be adopted drain well, and use sphagnum moss and peat in equal parts, with some pieces of charcoal intermixed. It requires cool treatment; indeed, it thrives admirably in a temperature of from 35° to 40° in winter. It is found about Loxa, also at Ibaguë, growing at elevations of 4000 feet and upwards.—EXPERTO CREDO.

TRIAL OF PEAS AT SEAHAM HALL GARDENS, SUNDERLAND.

All the varieties were sown on February 23rd, 1870.

REMARKS.

- 1.—Good for general crops.
- 2.—Good for general use; fine flavour.
- 3.—This Pea is the best of all the varieties to grow in dry weather, for after all the other kinds were ripe this kept green.
- 4.—One of the earliest varieties, and best.
- 5.—Quite a distinct variety; foliage light green; the pods are large, but well filled. I think in a favourable season it will be the best Pea out.
- 6.—Straw strong, and a good cropper.
- 7.—Best for early use, requires no stakes, and good flavour.
- 8.—One of the best for general use.
- 9.—A first-class variety; distinct and broad pods.
- 10.—A very good useful Pea.
- 11.—Much the same as Dickson's First and Best. A very useful variety.
- 12.—Much the same as Dickson's and Vanguard.
- 13.—A first-class Pea, worth a place. The pods are of a dark green.
- 14.—A very nice useful kind.

The seed was principally supplied by Messrs. Veitch & Sons, and I found it very good and true to name. I had the assistance of several gardeners to judge, and those remarked upon were thought superior to the others.—R. DRAPER.

WITNESSES.

(Continued from page 206)

Sown only in importance to draining is trenching, for the ground is free from weeds and its fertility is in a great measure dependent on the latter operation. It is quite as necessary for the ground as for that which has been some time under crop. For vegetables, fruits, and flowers, for shrubs and trees, the ground should be trenched—1st, Because it at least doubles

the depth of soil which can be easily penetrated by their roots, and consequently renders available for the plants' support a much larger amount of nourishment than would otherwise be the case; 2nd, It gives a free passage to rain, the decomposing matters in the soil are more equably distributed, and it admits air; 3rd, As the roots penetrate to a great depth before hot dry weather sets in, the plants in trenched ground withstand the drought and heat of summer much better than those in ground only surface-dug; 4th, It destroys weeds, especially those of annual or biennial duration, and, indeed, there are but few weeds that it will not kill. Exception must, however, be made of Thistles, Couch Grass, Bindweed, Dock, and a few others. The weeds being trenched down, instead of impoverishing the soil, contribute to its fertility.

Not only new ground is the better of trenching, but also that which has been several years under crop. The vegetable matter in the surface soil, owing to frequent manuring and the decay of the roots of weeds, and of the plants forming the crops, is considerably augmented every year, and this acts as a great stimulant to growth whilst the plants are young and their roots near the surface, but when the roots have passed down some depth the growth is weak, and unless watering be resorted to the produce is not equal to that of the plants in a young state. Another reason for trenching is, that in many cases the surface soil is little else than a mass of decayed and decaying vegetable matter. Little but leaves is produced, and though these are all we desire in the case of Spinach and some other crops, we require very different results when the produce we seek is the pod, the root, or the head. This excessive vigour of top causes the plants to be tender, and the growths are incapable of resisting extremes of heat and cold. What, then? Is poor soil best? By no means; but it is possible to present the food in such a manner that, whilst it gives early vigour, it will in the end prove injurious to the health and productiveness of the plants. The advantage of all digging consists in rendering the soil more open, and intermixing its parts. But how can this be effected when the soil is merely turned over? The surface is, no doubt, made all that could be wished for, but what of the soil lower down than 9 inches from the surface? There we have a solid mass not easily penetrated by the roots, and it receives none of the enriching matter given at the top, except that reaching it in a soluble state, and its constituents are principally inorganic matter.

Surface-digging, whilst it tends to make the soil for a few inches deep a mass of vegetable matter, is apt to cause disease in plants by producing that gross unhealthy development which is often attacked by the worst forms of disease, such as rust, mildew, &c. The richness of the surface often serves to encourage insect pests, which for their existence require soil long worked, or, in other words, full of decaying and decayed vegetable substances. It is well known to all cultivators that plants in old soil are more subject to the attacks of some kinds of grubs, or the larvæ of insects, beetles, &c., than those in fresh soil.

The action, then, of trenching, is threefold: it brings to the surface inorganic matter, it buries the seeds of weeds to such a depth that they will not germinate, and it destroys the larvæ of many insects injurious to plant life, or prevents their increase.

Some persons consider that whatever manure is applied should be given at the surface, and think that to bury it at a greater depth than a foot is to place it beyond the reach of the plants. This is a great absurdity, for plants, as a rule, root deeply; but in cultivation they do not so root, because their food is given on the surface, and the roots cannot descend if they would. We know that when plants have an opportunity they do root deeply, and are often difficult to restrain. Fruit trees exhibit this tendency, yet no one thinks of planting them without giving them a good depth of soil by trenching, or making borders of considerable depth, being at great labour to remove the bad soil, &c. Strange that persons doing this should advocate manuring on the surface! They tell us it keeps the roots there, which is also an error, for the roots go down, up, and sideways, wherever their food is and the way open. But if we do not keep the roots of Peas on the Quince stock, Apples on the Paradise stock, and of all bush fruit near the surface, they will be unfruitful from the roots going down. If there are no roots near the surface, there are none of any consequence anywhere, for the stocks are surface-rooting, and supplying them with food on the surface is simply feeding them in the only available place; but even that is of no avail, unless the roots in part have a depth of soil to draw their supplies

from in dry, hot weather. Either they must have a good depth of soil, or the application of water must be copious and frequent in a dry season.

Others, again, advocate deep digging, and putting the manure down. This method, too, is an error, for the ground being naturally of a deep, moist nature, the roots are attracted downwards by the looseness of the soil, and the results are sappy unfruitful growths. A good depth of soil would never do any harm if it were free from stagnant water. What, then, is the good of manure if it be erroneous to put it on the surface, and also to put it at the bottom of the trench? Placed on the surface and buried at the bottom of a trench it is all in a mass. The roots must turn upwards to get at the manure on the surface, or be satisfied with what is washed down to them by the rains, deriving no benefit whatever from the volatile substances ever vanishing in the air. Surface-manuring is well for fruit trees; in no other way can manure be applied without injury to the roots. On the other hand, placing manure at the bottom of a trench only feeds the roots that invariably find their way down to it, and this mode of applying manure is consequently adopted for subjects that remain long on the ground, as Strawberries and fruit trees generally, for unless the manure be given in the first instance, or prior to planting, it is impracticable to do so afterwards. Sometimes the manure is put at the bottom of the trench when the ground is intended for Carrots, Parsnips, and other roots, for it has been found that a rich surface soil causes the roots to branch or fork; and for Lettuce, Cauliflower, and other plants likely to suffer from drought, the same mode of application is advised, in order to give them increased moisture and support when they are beginning to head, and to keep them from running. Except for certain crops, I hold that all manure should be dug in and mixed throughout the whole depth of soil.

The operation of trenching is so well understood that I need not describe it, but a few remarks may not be without interest. If the ground is fresh land that has been in pasture, or been used for agricultural crops, we have to take out a trench. The top spit of a space about 2 feet 6 inches wide we take out and lay where we intend to finish. The top spit will be good soil in almost all cases, and we need not trouble further about that, but the next spit may be partly gravel, clay, or other material of no value on the surface. In this case we remove no more of the second spit than is of a nature likely to yield to the influence of the atmosphere—not gravel nor hard close clay. Instead of bringing such up it is better to loosen it with a pick, and give a dressing of fresh manure; indeed, I cannot perceive any advantage in placing very rotten manure at the bottom of trenches. If grass, we pare off the top about 2 inches thick, and place it at the bottom of the trench, and then take out the soil below that and place it on the top. The bottom is then picked up, and it is ready for the manure and the soil of the next trench. This is for a very poor soil, and one that will need manure at top, bottom, and in every way that is possible to apply it to keep it at all fertile. Very few soils are of this description; generally two, and in many cases three good spades' depths can be had. In any case the soil of the first trench or opening should be taken out until we come to sand, clay, or gravel; the former and latter it is useless to bring to the surface, and not more than 2 or 3 inches of the clay should be brought up at one time, and the same remark applies to any soil inclining to be more sandy, clayey, or gravelly than is suitable for plant-growth and forming a good tilth for sowing or planting. The bottom, whatever it may be, should be loosened fully a spade deep, and if there are two good spits of soil, there will be no necessity to manure the bottom if turf or the top spit of ground that has been under crop be turned over it. Between the second spit and the first it would be well to give a moderate quantity of manure, and in all cases I should give whatever manure is wanted at a spit's depth from the surface. This is all that need be done; only, if the soil be heavy it is well to throw it up in ridges, so that the frost may act upon it, and in February or March it may be levelled, or in any case it should be forked over before it is planted or sown. If the soil is poor it is desirable to give a liberal dressing of manure prior to the forking over early in spring. Indeed, some loams are so poor when the soil from a good depth is brought up, that without some stimulant to growth the plants put in take very indifferently, and do not advance much in growth. The manure in this case should be short.

In trenching, whatever weeds may be on the surface, take no notice of them, but place them at the bottom of each trench. November is the best month to trench, for then the bottom soil

is ameliorated by frost and exposure to the air, and becomes workable by the time of putting in the crops. All garden ground should be trenched every third year, and whenever it is very weedy turn the surface fully two spits under.—G. ANONY.

PEAS AND POTATOES IN 1870.

READING IN YOUR last number notices on Peas and Potatoes grown in 1870, I thought the following particulars might not be uninteresting to your readers.

Peas.—I sowed Daniel O'Rourke on November 29th, 1869, and gathered the first dish on May 28th, 1870. From Carter's Surprise, sown on February 23rd, I gathered on June 20th; from Premier Marrow, sown on March 10th, I gathered on the 24th of June.

Potatoes.—I planted Election Kidney on December 24th, 1869, and gathered the first dish May 28th, 1870. Sutton's Racehorse I planted February 23rd, and gathered on May 28th. Mona's Pride was planted March 12th, and the whole crop was gathered July 30th.

I had a continuous supply from the days on which the first Peas and Potatoes were gathered. The crops were all grown in the open ground without any extra attention or protection.—M., Ross, Herefordshire.

TOMATOES.

HAVING had good success in the culture of Tomatoes out of doors, I send a few notes, with the distinguished names of several varieties suitable for outdoor culture.

So much has been written on the subject by different able practical men, that it is almost impossible to say anything new; still, knowing the usefulness of the Tomato in both large and small families, how eagerly it is inquired for in the kitchen, and how much superior in quality home-grown Tomatoes are to those purchased in the market, I wish to point out that anyone with a warm border, or a south or south-west wall, need never despair of success.

In the first week of March the seed should be sown thinly in a 6-inch pot well drained, using about one-half fine leaf mould, and the remaining half loam, with a sprinkling of sand, and place it in a vinery or greenhouse. As soon as the seedlings can be handled, prick them out 3 inches apart in a pan filled with a light rich compost, consisting of fibrous loam to support the fine leaf mould one part, and the remainder old rotted manure mixed with sand. I place them to have plenty of fine leaf mould in the earlier stages of their growth, which encourages their young delicate roots.

In a fortnight after pricking out they should be ready for potting in 3-inch pots, using more loam and giving them plenty of drainage in this as in all their sittings. As soon as they get established give them plenty of air to keep them from becoming drawn, stake them with small sticks, and tie them loosely. Particular attention must be paid to tying them, as they are of very quick growth, and the ties soon out the stems, which are then liable to snap off just when the plants should be at their best. Immediately the roots reach the sides of the pot's report in 6-inch pots, using the same composition as before, the leaf mould may now be a little coarser—say half-inch. Reporting directly the roots reach the sides of the pots, till the plants are placed in their fruiting pots, is one of the points to be attended to, as helping to keep them clean, healthy, and steady in growth. I report when the plants are ready, in 9-inch pots, and lastly, in 12-inch pots, using a coarser soil this time, and placing a few inch bones above the crocks.

I have the plants hardened-off for turning out in the summer's quarters by the third week of May. I should be glad that I have had good fruit of plants potted from the seed-pots in 6-inch or 9-inch pots, though I prefer those treated in the way I have described. Abundance of water should be given both to the root and top, never, if possible, allowing them to flag from want of it. Should they, before they are planted in their final quarters, show any trace of green fly, give them a syringing of water in which soft soap has been dissolved at the rate of 2 ozs. to the gallon, turning the plants on their sides. In fact, to make doubly sure I syringe them clean or unclean, as I believe the soft soap is very distasteful to insect life.

The plants being now ready for planting, they should be plunged at once in the border, giving them additional stakes for support, using one or more according to the style of training and the room there may be. I have used only one

stake a yard high, tying the plant to it as required, and pinching the shoots one joint above the flowers. I have also used one stake in the centre of the pot, and one on each side in the border, at 9 inches apart or more as convenient. This is a good way of training them, but the best plan of all when it can be done is to nail them to the wall, plunging the pots when convenient; but sometimes when I have had open spaces between the fruit trees on the walls, I have trained the plants over these, but I could not plunge the pots more than a few inches owing to the roots of the trees. When grown on a wall particular attention should be paid to the thinning of the shoots and nailing-in, and where there is room they can be made to cover a great space and will look very effective.

I seldom find manure water required till the fruit is swelling-off, but should rich compost not be at hand, watering with liquid manure is very beneficial. Where fine fruit are required rather than quantity, they should be thinned as soon as set, leaving one, two, or more fruit on a cluster as required.

I will enumerate the kinds suitable for out-door culture here. The first on the list and the best is General Grant. This is the finest Tomato I have cultivated or seen, single fruit weighing from 4 to 8 ozs., and to these weights I have grown from twelve to twenty fruit on a plant. It is not the earliest kind, though I gathered in the first week in August, and the fruit ripened in October are as firm and plump as those first produced; in fact, its keeping qualities are good, and the colour beautiful. This variety is a sure cropper, but requires more head room than some. The Old Red comes next in size and quality. This is a well-known variety and is very dwarf; it is also the latest in ripening, but gives way to General Grant in its keeping properties. The Orangefield is the earliest with me and very prolific; this should have a place in every garden, for though the fruit is small it comes in remarkably early, is very dwarf, and, as I said before, very prolific. Kaye's Early Prolific is very good, but is inferior to the Orangefield. This variety is known by the peculiar foliage, which has the appearance of suffering from want of water. Tomato de Lave is the last of those grown by me. This is very dwarf, scarcely exceeding 18 inches in height, still I have no doubt it might grow higher with coarser feeding. It is a very useful variety.

In giving the preceding list I do not for a moment wish to say that they are the only varieties suitable for out-door culture; no doubt there are plenty, but the above are what I find good. Where the space is limited the Orangefield for the early crop, and General Grant for the late one, are all that are required.—STEPHEN CASTLE, *Bent Hill Gardens, Prestwich.*

THE REV. C. P. PEACH'S GARDEN,

APPLETON-LE-STREET, YORKSHIRE.

It is not the description of a grand garden or "show place," in the usual acceptation of the term, that forms the subject of my theme; its title recalls no thought of extensive grounds, no vast ranges of glass houses, hardly any of the characteristic features of gardens of note, and yet I doubt not that it will be read with interest by all caring for a flower garden, and who have, like myself, profited by reading Mr. Peach's excellent communications in these pages. It was through one of those exhaustive papers on bedding Pelargoniums that I first became aware of the merits of Violet Hill Pelargonium. I had never seen it; but so convincing were Mr. Peach's notes on it and certain others, that I felt no hesitation in ordering those kinds which were perfect strangers to me, and certainly I have found most of them to be all that he has said of them. I qualify this last sentence, because some kinds of sterling merit do not succeed so well with Mr. Peach, or, rather, I should say, in the climate of Yorkshire, as they do in the south of England. As an instance of this I will take Crystal Palace Gem, which in Kent and in the neighbourhood of London far surpasses all others of its class that I have seen, being very compact in its habit of growth, with its finely shaped foliage so stout in texture that it never burns, but retaining its deep rich yellow colour in all its purity and freshness throughout the hottest summer, no matter how exposed it may be, thus proving a great acquisition; for who that has had much experience of bedding plants has not had to endure the vexatious loss of foliage in Golden Chain, the whitened surface or scalded margin of that of Cloth of Gold, or the vulgar gloss of Golden Fleeco? But, unfortunately for Mr. Peach, Crystal Palace Gem is anything but a gem with him, as it becomes so green as to be almost worthless. Need I point the moral? Well, I may just observe that severe

criticism would frequently assume a much milder tone if the effect of different climates, aspects, and soils on other things as well as on bedding plants were borne in mind.

To show how careful Mr. Peach is not to mislead the public, I may mention seeing a plant of Pelargonium Crimson Nosegay growing along with other novelties in a little trial garden, and upon my inquiring why favourable mention had not been made of it, Mr. Peach replied that he thought it a good variety, but as he had not seen much of it he refrained from assigning it a place in his list, which I can confidently say it fully deserves, for it is one of the most distinct and splendid sorts we have. Its very compact yet spreading habit of growth is all that one could desire, while the light blotch on its foliage causes its profusion of flowers, of a deep rich liquid crimson, to appear all the more striking.

The chief feature of interest in this garden is a long sloping curved border, partly enclosing a pretty flower garden in front of the vicarage; it is on this border that a number of the leading kinds of bedding Pelargoniums are grown and their merits compared. It is divided into many compartments in a very tasteful manner, with broad lines of *Arabis alpina* variegata so arranged as to form a band of diamond-shaped spaces along the entire length of the border. Each diamond contained a distinct sort of Pelargonium, and thus each variety fully displayed its good or bad qualities, and, by comparison with its neighbours, afforded the fairest test of its relative merit. A border of this description must be such a constant source of interest throughout the entire summer as to be far preferable to the most brilliant ribbon border, however perfect; and by introducing suitable plants in the vandykes or half-diamond spaces along its sides, it is rendered as attractive an object in its way as it is possible to conceive. Moreover, by such an arrangement a much fairer idea of the real merit of new varieties is to be had than could ever be gained from a sight of the single plants of our exhibitions, and which are generally all the material that a Floral Committee has on which to found its decisions.

It is not my purpose to give a detailed statement of the varieties of Pelargoniums grown by Mr. Peach, as he has already done so, but I may observe that among many new kinds of the Gold and Bronze section Crown Prince and Impératrice Eugénie appeared to be the best; and from a fine batch of specimen pot plants of the Nosegay class in one of the greenhouses I selected Mrs. Living, a remarkably free-flowering orange scarlet; Godfrey, of a similar shade of colour, but brighter and with very large trusses; Gloire de Corbeny, of a fine salmon shade; and Ne Plus Ultra, with immense trusses of bright pink flowers.

A mass of deep-coloured Beet surrounding some Centaurea in the flower garden had a tolerably good effect, but its vulgar glossy foliage will, I think, prevent its ever becoming a general favourite for such a purpose. A very compact-growing dwarf blue *Lobelia* named Little Gem was very good indeed; it is a lovely free-flowering variety, worthy of a place in every garden. Nor must I omit to mention a fine bed of mixed kinds of *Verbenas* enjoying a prominent position; and very worthy of it they were too, for to my mind there was not a more attractive bed in the entire garden. I never can understand what is meant when we are told that many of the best show varieties of Perry and Eckford are not good bedding plants. Planted thickly in deep, rich, cool soil, and with a little care in training and pegging, they form a lovely and interesting mass of bloom, which is quite certain to attract and please the most fastidious eye.

The glass houses are moderate-sized span-roofed structures, very compact, and with every inch of space turned to account. The plants which they contained were in a very healthy and creditable condition.

Some low portable frames, very useful and wonderfully cheap, were shown to me, and as they must be very serviceable for a variety of purposes I will give a slight sketch of them. They are made in two shapes; one is a regular span-roof, and the other a half-span. The span-roofed frames are undoubtedly the more useful of the two; they were 9 feet long by 3 feet wide, 11 inches high in the centre, and 3 inches high at the sides; there is a wooden division across the centre to which the sides are nailed, and so they are kept from warping. The panes of glass are moveable; they fit into a groove in the side of the ridgebar, and are kept securely in their places by a crooked pin at the bottom of each pane. The panes measure 16 inches by 20, and it takes seven of them along each side of the span. The cost of these fourteen panes is 8s. 6d. The boarding costs 3s., the painting 1s., and the making 3s., and so

we have a capital little glass roof, which you may set up as high as you like on bricks, and covering a space of 27 square feet, at a cost of 15s. 6d. I have seen no ground vinerias nor plant-protectors to equal these frames either for cheapness or utility, and for that reason I have endeavoured to describe them accurately. If I have omitted any important particular I am sure Mr. Peach will willingly correct me.—EDWARD LUCKHURST, *Old Lands, Buxted, Sussex.*

PEAS IN 1870.

REFERRING to the comments on my article on Peas by Messrs. Carter & Co. on turning to my note-book I find that on July 9th, 1870, what I obtained for Ringleader (Sutton's) measured 3 feet 6 inches in height. The seed I procured in 1869 from a well-known firm in Manchester, at the same time I had a packet of Carter's First Crop from another firm here; both were sown at the same time and received the same treatment, but I saw almost immediately that they were two distinct varieties. Being fully aware of the old story respecting the two Peas, I determined to save my own seed of Sutton's Ringleader, and in order to have it fine I saved the pods that were well-formed, and with not less than five fine Peas in a pod, and the result this year has been the best row of Peas I ever saw, and certainly there are those in this neighbourhood who can bear testimony to what I say. I should add, the height last year was 3 feet. This year, though I grew Saogster No. 1, Dillistone's Prolific, and what was sent to me as Carter's First Crop, none proved equal to my own saved seed. I have saved this year sufficient for a single row, and at the proper time I shall, in order to get the First Crop true, send my order to Messrs. Carter & Co. for this and Laxton's Prolific. I have now before me two catalogues for 1870, of well-known old-established firms. In one, the height of Ringleader (Sutton's), or First Crop (Carter), is given at 3 feet, which is the height it grew with me in 1869. In the second, Ringleader and Carter's First Crop are made to read as distinct varieties. In conclusion I would ask, is it not possible for a system of high cultivation to raise the height of Peas? In my case I have proved that it does.

Coming to Mr. Gilbert's remarks, permit me to inform him that all gardeners are not aware of the fact of Peas requiring the ground being prepared as I have described, because, if they knew, I should both see and hear less of failures than I have been accustomed to do, as no one can make me believe that for the sake of a little extra labour he would endanger the crop of what I consider the best of vegetables.

In the next place, I hope Mr. Gilbert does not compare Manchester to Stamford, Prestwich being the same distance from Manchester as Burgley is from Stamford; if he does he is certainly wrong, both as regards rain and smoke; and, as I said, my Peas sown in March were as early as those sown in the previous November, leaving out of the question birds and mice. I speak this from experience, and certainly I consider my Peas gathered on the 18th of June as early as his gathered on the 6th of the same month.

Lastly, I can inform Mr. Gilbert, that to have Peas in October on this side of Manchester must be very rare, I myself having seen none; in fact, the subject of my earliness and lateness in Peas is spoken of by many, though I still hope to have later gatherings the coming year, though I despair of gathering here on Lord Mayor's day.—STEPHEN CASTLE, *Bent Hill Gardens, Prestwich.*

MESSRS. CARTER & Co. in your paper of the 3rd inst., page 345, say that "it is utterly incorrect that Sutton's Ringleader is 3½ feet high," and that they "challenge anyone to name an early Pea of 3½ feet high," which is earlier or so early as Carter's First Crop. As an amateur I have grown Sutton's Ringleader for two years; each year it has grown 3½ feet high, and would, I think, have reached 4 feet if it had not had the tops frequently pinched off. Daniel O'Rourke grew 4½ feet high, though it is neither earlier nor so early as Ringleader. There could be no mistake about the seeds, as I had them

direct from Messrs. Sutton. I think Messrs. Carter should make allowance for different qualities of soil and situation before they make such sweeping assertions as those expressed in the letter from which I have quoted.

I should be happy to give you some information as to the results I have experienced after cultivating in this northern climate a variety of dwarf Pear and Apple trees purchased from Mr. Rivers in 1864, if it would be of any interest.—E. H. D., *Lattendales, Penwith, Cumberland.*

[We shall be obliged by your notes.—Eds.]

MESSES. CARTER & Co., High Holborn, have issued a list of very liberal prizes which they offer for Mangel, Swede and other Turnips, Carrots, Beet, Parsnips, and Cabbages. Those who intend to compete should send at once for a schedule, as specimens must be sent by the 20th inst.

USE OF A DAMPER—CIRCULATION OF HOT WATER.

WHAT is a damper fixed into a furnace chimney for? I say it is to regulate the draught of the fire from the boiler, and ought to be kept closed, or nearly so, when the heat in the houses is up to the degree wanted, as the damper confines the heat round the boiler, and also keeps the fires in during sharp frosty nights.

One more question. I can never get our fernery heated to more than 55° this dull weather, and often find the temperature down to 40° or 38° these cold mornings. Last winter I could hardly keep frost out at all. There is plenty of 4-inch piping all round, but it is the setting, for where the pipes which go all round the house enter from the boiler, they are higher than the other end by nearly a foot; consequently the water does not circulate. At one end of the house the pipes are hot, and at the other nearly cold. My employer says he had this done to keep one end warmer, but I think it a very unscientific idea altogether. Did ever hot water go down hill? I will not believe it will, and as a proof, last winter was so severe, and I had to keep up such a large fire, that in trying to get the house up to a certain heat the pipes burst close to a joint through the pressure. There are no air-pipes in the elbows. What can a gardener do? Just for the sake of a few shillings to have the pipes readjusted in a proper position, and not to hear reason, an employer sees his plants half dead all the winter; besides the double amount of fuel consumed, and argument and strife between employer and employed.—*POOR GARDENER.*

[On the general question I agree with you, if the matter is stated correctly, and consider that your employer's ideas on heating are altogether wrong, and if continued to be carried out will not only be a source of unpleasantness to the gardener, but of great loss and waste of fuel to himself. There is one matter to which I would allude, and that is the question "Why should an employer interfere with a head gardener's management of his fires, &c." Why, indeed! But then you must own he has a perfect right to do so—nay, more, it would often be to the general advantage if this were more done than it is. Many a ton of coals would be saved, and the labour of the stoker made lighter, if employers more thoroughly entered into this and other matters. I say thoroughly, because no intelligent gardener could long put up with mere ignorant meddling for the sake of meddling. But this I will say, that the employer who knows most about firing and stoking will be the most considerate in estimating the labours and attention of the fireman. The more generally intelligent even on gardening an employer is, the worse it will be for a mere pretender but the better it will be for an intelligent attentive man, who does not only know but practise what he knows. In many cases here-

before I have shown that I can stand up for the gardener, but with all that I must still come to the conclusion that the man who spends the money in a garden has a right to spend it in his own way, and if one of these ways should be that heated water is to be forced to run downwards as a general principle, then the gardener, having courteously stated his opinion, and finding that the places cannot be heated on that principle, must be content with these disadvantages or take his services to a more appreciative market.

Now to the general matters. I never like a damper to be quite closed, as that is dangerous, and, perhaps, a hole from half an inch to an inch in diameter in the centre is as good a safeguard as any. If the damper is not for the purpose you state, what is its use at all? If your employer is right in having it always out, what is the use of having it? Would it not be better to have none? Or, by the way, does he think that by the damper being always out there would be a stream of cold air always beating back the hot air round the boiler? I would rather use even in this respect the damper in the usual way, and have a small opening for fresh air beneath it. I can think of no other reason why a scientific engineer should wish the damper always to be out in connection with a furnace that heats a boiler.

I do not see how you can heat the fernery properly—though there are plenty of pipes—with the pipes where they enter the house a foot higher than at the farther end, and no openings or air-pipes. No wonder your pipes burst, and you get no heat to speak of at the farther end. Still it would be wrong to say, "Did ever hot water go down hill?" for with atmospheric pressure it will do so, though not in such close pipes as yours. With an elevated cistern open, and an open air-pipe at the farther end, there would be circulation. Even with an open air-pipe a couple of feet above the pipe where it enters, and one 3 or 4 feet high at the farther low end, I would not despair of circulation—in fact, I see it in operation daily, but then the plan is not so good as when the pipes are on a level throughout, or with a slight rise to the extremity, and a small air-pipe inserted at the highest point. The air-pipes might be tried before lifting the pipes; but if even that be done, the heating will never be properly effected, and the firing must be alike expensive and dangerous. As to advice, I do not see how I could further help you. There are matters with which a stranger cannot well intermeddle. I know this, that no gentleman will find it to his advantage to lower a head servant whom he wishes to keep before that head servant's assistants. Another thing I have often thought of. I once heard some man complaining of a grievance to the late Dr. Lindley. "Well," said he, "I cannot sympathise much with you, I have got now such a rhinoceros hide that each bitings as these would never be felt by me." Well, I suppose some of us get thicker-bided as we grow older; but there are some things which one cannot stand, and should make one change rather than endure.—*R. FISH.*

AMONG THE CHRYSANTHEMUMS.

Go into what quarter of London you will, there at the present season you are sure to meet with this autumn flower. In some cases you will find it, to use a gardener's expression, "well done," in others "ill done;" but still you will find it. Up north and to the west you will find it in perfection; on the south side very good; "down east" we have not travelled much of late, yet we are assured, despite all drawbacks—smoke, and foul air, and poverty—there, too, the Chrysanthemum is cherished. Well it deserves to be so; it enlivens what is generally in London the gloomiest month of the whole year; in the poor man's fore-court, in the rich man's conservatory, it is equally welcome; it flourishes in an old teapot in an attic window, and adorns a costly vase. Its powers of withstanding smoke, and the brightness and variety of its colours, render it one of the best of London plants, and by Londoners it is duly appreciated. It is, however, more especially up north that the Chrysanthemum has found a home. Stoke Newington was the place where the mother Chrysanthemum society took its origin, there the flower is still fostered with every care, and thither we shall first bend our steps and visit.

MR. FORSYTH'S, BRUNSWICK NURSERY.—Here the show house, arranged much the same as in former years, is certainly quite as attractive. It would be tedious to name all the fine varieties which are here to be seen, especially as we have given them from year to year, but a few of the best we will particularise. White Globe is this year generally fine, and the blooms

are of remarkable size and beauty; Mrs. George Rundle, another white, though not nearly so large, is one of the finest kinds known for specimens; two plants of it which Mr. Forsyth had for exhibition were models in respect to growth, and covered with bloom. Of Queen of England, blush, there were blooms quite 6 inches across; Beverley, white, was very fine, as it usually is; and Golden Beverley, a sport from the former, equally fine in its shade of colour. The following were very conspicuous—viz., Prince of Wales, purplish violet, very large, and finely incurved; Prince Alfred, rosy crimson; Princess Beatrice, rosy lilac, with a silvery tinge, and peculiarly beautiful; Faust, bronzed crimson purple; Bronze Jardin des Plantes; Le Grand; Lady Harding; Little Harry, not large, but excellent for specimens, and a charming flower; Princess of Teck, white; Lord Derby, finely incurved, dark purple, and of very stout substance; Lady Slade, beautifully incurved; Hereward, very fine; and Jardin des Plantes very rich in colour. Virgin Queen is of the purest white, and very fine; Pink Pearl, though small, is very pretty; and Empress of India, white, is very large and beautiful. Venus, likewise, is very pretty.

Duchess of Roxburghe, large and with broad florets, orange, tinted with rose, is a fine incurved flower, sent out in the present year. Another new one, Mr. W. H. Morgan, a seedling of Jardin des Plantes, but lighter in colour, is said to exceed its parent in size, but at the time of our visit it was not far enough advanced to judge of this. Robert Bruce, rich crimson, had not attained its full size, but is said to be even better than Dr. Sharpe for specimens, and how good the latter is the five plants which Mr. Forsyth has are a sufficient proof. Mr. Cole, blush, promises to be a good addition to the Anemone-flowered class.

The Japanese kinds, so excellent for conservatory decoration, being for the most part later than the incurved kinds, were not at the time of our visit all fully out, but James Salter, lilac, a highly-decorative variety, and Dr. Masters, yellow, with an orange centre, were in full beauty, and very large and showy they are. The Daimio is another splendid kind; Red Dragon is rich in colour; while of ambers and yellows there is a superabundance in Comet, Meteor, Jupiter, Prince Satsuma, and The Mikado. Chinese Orange Incurved was noticeable for its size and being beautifully incurved; the florets are streaked with red on the inside.

In running through the houses, which are filled with bedding plants and a large stock of others which Mr. Forsyth employs for an extensive furnishing business in the west end, one meets with many excellent specimens of Pompon Chrysanthemums, especially of the different kinds of Cedo Nulli, Golden Aurore, Salamon, Bob, &c., and such of the large-flowering class as Annie Salter, Defiance, and Dr. Sharpe.

THE TEMPLE GARDENS.—The late Mr. Broome—our worthy kind-hearted friend Broome—who did so much to popularise the cultivation of the Chrysanthemum, not only in London but all over the country—who with heart and hand entered into every movement which was likely to advance the interests of his favourite flower—he has passed away, but he has left his mark. It was one of his ideas to have the long border facing the river, where his best specimens were, covered with glass, and that has been done this year, and a very great improvement it is. His successor, Mr. Newton, deserves great credit for the manner in which he has kept up the reputation of the Inner Temple Gardens by the excellent display he has made, and which from the improvement just noticed, is seen to much better advantage than the shows of former years. As usual, both to it and Mr. Dale's, in the Middle Temple, there have been thousands of visitors.

The best border, as it is termed, is about 35 yards long, and from its extent is filled with a great number of fine varieties. The following may be noted as the most conspicuous for the size and beauty of their blooms—viz., White Globe, Beverley, Virgin Queen, Jardin des Plantes, Golden Beverley, Guernesey Nugget, Lady Talfourd, Faust, Prince Alfred, Christine, Attraction, Prince of Anemones, Mrs. Huffington, Mrs. Sharpe, Progne (fine in colour), and Mr. Brunlees; and among the Japanese, James Salter, The Tycoon, and The Daimio.

Great improvements have been effected to these gardens since the Thames embankment works approached completion, by widening the terrace and laying out the beds afresh, and yet more are in contemplation. The principal beds, much enlarged are now planted with bulbs, so we may anticipate a good spring display. Mr. Broome's mantle seems to have fallen on a worthy successor.

IN THE MIDDLE TEMPLE GARDENS, Mr. Dale has a less extensive display under cover, but the blooms both in size and perfection are everything that can be desired. Guernesey Nugget, primrose, is very fine, so are White Globe, Jardin des Plantes, Little Harry, very pretty, General Slade, Nil Desperandum, Antonelli, Prince of Wales, Astrolabe, Cherub, Rev. Joshua Dix, Lady Harding, St. Patrick, Sparkler, and Mrs. Halliburton, the last a charming little flower.

In the beds and borders Mr. Dale is always strong in Pompons, and this year they present a fine mass of bloom. The different sports of Cedo Nulli, Canrobert, Salamon, Mrs. Campbell, Madame Rousselon, Dru Drin, an old sort, but still one of the best; Darullet, St. Justine, and Madame Pèpin, form fine masses. Mr. Murrey, a violet rose hybrid kind, is also very attractive, so is Julie Lagravère, one of the small-flowered kinds of the large-flowering class. Mr. Dale may well be congratulated on his success this year, although he has long been known as one of our best Chrysanthemum growers.

GARDENERS' DIFFICULTIES.

THE difficulties of the season prompt us to take the opportunity of saying it would be well if the employers of gardeners took such matters more into consideration when expecting the regular supply independently of what the weather and the season may be. And, again, it would be well if we gardeners in general, though appreciating the consistency and the kindness of such consideration, would yet trust as little as possible to it, but do everything to make up for drawbacks and deficiencies, so that these should be felt as little as possible. This is the best course, at least for us, to pursue, and the man who adopts it, if there should still be some talk of deficiencies, will have the self-satisfaction of feeling that he did what he could, a matter of great importance so far as true happiness is concerned. We know of cases where the knowledge of drawbacks connected with the dryness was well known and sympathised with; but the drawbacks were forgotten, and the usual returns at once expected at the first favourable change in the weather. We fear that there might be cases in which the gardener depended rather too much on sympathy, and not enough on his own additional efforts to prevent the drawback being much felt. Employers cannot be expected to be so taken up with all drawbacks as we are. An early frost will make havoc with fruit blossom, but that is forgotten in the fruit season. Early-bedded-out plants may be almost cut down to the ground, but though planted in obedience to orders, the casualty is apt to be forgotten when there is a deficient massing of early bloom. A thunder or a hail storm may do much mischief, but we suppose it is natural to forget, or at least not desire to have these matters broadly obtruded in fine weather and bright sunshine. Very often after such a casualty the mild zephyrs will blow, and the sun will shine brightly as if to tantalise us. It is often impossible entirely to neutralise such evils, but much may be done by way of prevention, and much in the way of mitigation, so as to keep the effects from being so much seen and felt as they otherwise would be. We may rest assured that all drawbacks and difficulties are apt to be forgotten as soon as they have passed away, though without extra effort and thought the results would be long seen and continued. It is best for all parties that defects, even from unavoidable causes, should be as little seen as may be. The subject embraces many sides. We do not now enter upon such a case as where there is a recognised agency continually at work undermining the efforts of the gardener, who can only do his duty by these matters being thoroughly recognised. It is more ordinary drawbacks from seasons and circumstances to which we would refer, and our meaning may be rendered more clear by two or three illustrations.

During the past season some gardens would have been little better than a desert without mulching and shading. We heard of one place where the bedding plants had been turned out rather early, and were much injured by frost, and were then philosophically left to their fate, a fate involving great disappointment. We heard of another similar case, but the extra care and bringing in small reserve plants prevented the evil being at all seen by the middle of July. A lot of bullocks got into a flower garden, trampled the beds in the end of June, and tossed and broke the flowers, and it was to a great extent left to its fate. Another had been invaded by sheep breaking through and scarcely leaving a green thing, but by increased energy, with other plants, annuals, &c., the garden was soon very attractive. A gardener was told that the men must be

reduced for a time, and he then left some favourite flower beds unfilled, though nothing would have been said if he had left uncropped or sown down the half of the kitchen garden. We will not now agitate the question as to who would be the most trusted servant of these men, we shall be satisfied if our young readers merely decide who was the most likely to feel the

greatest amount of self-respect and satisfaction. Be assured all drawbacks, even those over which we have no control, will soon be forgotten, and it is true wisdom to prevent them as far as possible from obtruding in their results upon the attention. It is better to remove a tree than leave it standing after it has been scathed and blighted.—R. F.

CASTLE HOWARD.

THE SEAT OF THE EARL OF CARLISLE, NEAR YORK.

No. 2.

In the centre of the garden is an elegant fountain (*fig. 4*), to the right and left of which were two fine bold groups of beds precisely similar in appearance. Each group was composed of a central pedestal supporting a tazza well filled with Pelargoniums, surrounded by four circular beds alternating with a like number of curved-out parallelograms; the circles contained Pelargoniums, and the parallelograms Hollyhocks. Along the extremity of the flower garden is a fine raised walk, forming a most agreeable and commanding promenade. At one end of this walk is a striking group of statuary representing Hercules wrestling with Antæus, and at the other end there is an equally bold representation of the Rape of Proserpine.

From whatever point of view one looks at this fine flower garden its appearance is entirely satisfactory. It is the work of

Mr. Sutherland, the gardener, and reflects much credit on his taste and skill; it is not only very elegant in its design, but by its fine proportions and the chaste character of its accessories it is peculiarly suited for its important position.

From the raised walk another walk leads in a straight line under the overhanging branches of trees, to a commanding figure of Apollo, standing on a rough-hewn pedestal of rock, on a circular plot of turf, encircled by the walk margined by Lime trees. At right angles with the walk leading to this spot from the flower garden is another fine walk up a Lime avenue, so that it will be understood how very suitable this figure is for the situation it occupies. A noble walk leading in a straight line from some important part of a garden or pleasure ground, or from the mansion itself, should always have some object of interest at

Fig. 4.—The Fountain.

its extremity, as an important work of art, or a noble specimen of some choice kind of tree, or else lead to a commanding position overlooking fine scenery.

Opposite the garden front (*fig. 5*), I was shown an Irish Yew planted twenty years ago by Her Majesty the Queen, and a *Cedrus atlantica* planted by the late Prince Consort; both trees were in a thriving condition. Many handsome specimens of Wellingtonias, Deodars, and some fine Cedars of Lebanon were dispersed about the grounds.

The kitchen gardens are very extensive, there being nearly eleven acres enclosed by fine walls, with interior cross walls. The principal entrance, with its ornamental stone pillars and elegant gates of ironwork, presents a fine appearance. Many of the walks had ribbon borders along each side, all very bright and beautiful. Some persons possessing peculiar views concerning the fitness of things object to such bright floral displays in the kitchen garden, but where space can be spared to fringe the walks with lovely flowers by all means let us do so. A well-

cropped kitchen garden, with its beds of flourishing vegetables arranged with geometrical precision, its symmetrical fruit trees, and the freshness and peculiarly neat appearance which everywhere prevails, is a very attractive sight, fraught with interest and instruction; and if to this we can impart an additional attraction by the aid of a bright flower border or two it is surely wise to do so. I am myself at present engaged in making a new kitchen garden, and by the wish of my employer there will be flower borders along each side of the central walk, which, as it is in a fine sunny position, will form an agreeable promenade; and I was amused at the exclamation of a visitor lately, "What! Flowers in the kitchen garden!" which he evidently considered rank heresy.

The ranges of glass houses are not all together, but are so scattered about—it I may use such a term—as to present a somewhat disjointed appearance. In a fine lean-to each house, the trees, trained to a curved trellis along the front part of the house as well as on the back wall, were in a very healthy and

vigorous condition. Mr. Sutherland spoke highly of Prince of Wales Nectarine, which had fruited well in this house. In another Peach house the condition of the trees was equally satisfactory. In a long low vinery the Vines had an even crop of fruit, not very large in the bunch, but with good-sized, well-coloured berries. Madresfield Court is a splendid new Grape; it had a good crop of long taper bunches, and its fruit, which I was allowed to taste, has a delicious Muscat flavour. This fine

variety is worthy of a leading position among our late Grapes. The Peach trees on the open walls were bearing well. The culture of hardy fruits evidently receives much attention here. A collection of pyramidal Pears were really magnificent trees. The collection of Apples was even more extensive. The bush fruits, too, occupied a very considerable space, and I particularly noticed some fine standard plants of Red Currant. The crop of Strawberries had been good, and Mr. Sutherland agreed with me

Fig. 5.—The Garden Front.

that Dr. Hogg is one of our most valuable kinds; it had been particularly fine here.

The soil of this garden is a fine deep rich loam, and the vegetable crops growing in it were abundant and good. Myatt's Prolific Ashleaf Potato is a favourite kind here. A heavy crop of it was being lifted at the time of my visit. I was also shown some fine crops of various new sorts of Potatoes, such as Early Rose and Climax, but refrain from any farther mention of

them, as Mr. Sutherland purposes contributing a paper on this subject.

And so I left Castle Howard, after experiencing much kindness, to which Mr. Sutherland added by assisting me on my way to see Mr. Peach, whose practical and instructive papers we all read with equal pleasure and interest, and concerning whose garden I will tell a little in another paper.—EDWARD LUCKHURST, *Old Lands, Burted, Sussex.*

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE great amount of rain which has fallen recently has generally interfered with the progress of out-door operations. All fine days should now be turned to account and held of value, owing to the uncertainty of their recurrence. As full-grown *Coleworts* turned into heads, like young Cabbages, are rather impatient of frost, it is advisable at this period to take them up and heel them in near the frame ground as thickly as they can lie together, covering them up, as soon as they are slightly frozen, with new straw, and laying a few stakes on them to prevent the wind removing the straw. By these means the ground is set at liberty for trenching, and one can preserve with certainty fine young Cabbages all the winter. Whatever may remain of *Celery* earthing should in favourable weather be attended to. The weather has favoured the eluge, if nothing else lately; they must be closely looked after, or the destruction of the young and tender Cabbages and *Lettuces* will infallibly be the consequence. *Haricot* and *Kidney Beans* not sufficiently matured for preservation for seed, may, nevertheless, be supplied to the table. They will form an excellent

and wholesome dish. Place some straw covers or old lights on the best *Parsley* bed, for fear of snow, also on the *Normandy Cress*. Look well to winter salads. Plant *Shallots* on raised beds; dig plenty of manure in, burying it deeply, and surround the bulbs with sand in raised drills, covering the bulb just overhead. Protect from frost *Rhubarb* intended for forcing, and remove all dead and decaying matter from both the *Rhubarb* and *Sea-kale* beds. Any kitchen gardener without a tank to receive the drainage of the dung-heap, or for the mixture of manure water, should speedily remedy the omission.

FRUIT GARDEN.

In planting and selecting fruit trees for the kitchen garden it is of great importance so to prepare the soil that the trees shall be as far as possible independent of extreme seasons, whether of moisture or of drought, also to take care that they do not make superfluous wood, giving much extra trouble to the pruner, and choking the surrounding vegetables or flowers. To accomplish this, it is found by experience that limitation of the roots is absolutely necessary, more especially as to depth. High planting also tends to the same result, but this in itself

is not complete, inasmuch as it cannot provide against the vicissitudes of climate, which provision, as before observed, should be the keystone of the arch. Thorough drainage is the first step, provided the soil harbours moisture. This being properly accomplished, some good strong loam should be provided if possible, be the soil what it may (unless a new garden and of a heavy nature), in order to mix with and refresh the old soil, which in the majority of old gardens is what is termed effete or worn out, however imposing its colour and consistence may be. Eighteen inches of sound soil for the average of fruit trees is considered better than a greater depth, provided top-dressings are made use of in very dry and hot periods. This should be placed on a mound (6 feet square) of brickbats or broken stones covered with a coating of cinders to keep the drainage porous. The limits of a calendar will not allow of more being said on this head; it may, however, be acceptable to enumerate a few fruit trees which ought to find a place in small as well as large gardens, merely premising that the list is not to be considered complete in itself, but merely as furnishing a few hints. Of *Pears*, procure the Jargonelle, Dumore, Marie Louise, Aston Town, Althorp Crasanne, Fondante d'Antonne, Paase Colmar, Winter Nelis, Glou Morcean, Ne Plus Meuris, and Baurré de Rance. *Peaches*—Pourpice Hative, Royal George, Noblesse, Bellegarde, and Late Admirable. *Nectarines*—Etruge, Violette Hative, and Old Newington. *Apricots*—Breda, Royal, Shipley's, and Moorpark. *Plums*—Précoce de Tours, Orleans, Reine Claude Violette, Washington, and Lekworth Inégatrice. *Cherries*—May Duke, Downton, Elton, Bigarreau, Late Duke, and Morello. These stand nearly or quite in the order of their ripening. In addition to these, of *Apples* procure the Early Harvest, Kerry Pippin, Early Nonpareil, Ribston Pippin, Pearson's Plate, Pitmaston Nonpareil, Old Nonpareil, Starmer Pippin, and Lamb Abbey Pearmain, all table fruit. As kitchen Apples, Manks and Keswick Codlin, Bedfordshire Foundling, Blenheim Pippin, Dumelow's Seedling, Wheeler's Russet, and Northern Greening. To these may be added others of very excellent character. Anyone, however, desirous of planting a moderate-sized garden would do well to obtain these kinds.

FLOWER GARDEN.

During the present month more than common attention is required to preserve the garden from the desolating effects of the weather; all traces of the sedulous care and cleansing of one day may be effaced by the storms of the next. Flat or ill-drained and constructed gravel walks will suffer from depositions of mud from pools to which such walks are liable, which, if not removed immediately, will destroy the appearance and value of the gravel. Examine all gratings, drains, and watercourses, and prevent as far as possible the evil above alluded to. The value of a well-drained exposed walk, free from the shade and moisture of trees, will be appreciated by those who recognise the importance of exercise and fresh air in all weathers and seasons. Walks subject to moss had better be raked and left in a rough and loose state during the winter. Proceed with planting; the present is the best time for removing large evergreens. Roll and cleanse lawns from worm-casts; lime water may be employed to destroy worms if too numerous. Transplant Sweet Williams and single Wallflowers into borders to replace the gay but tender beauties which fade on the approach of winter. Plant bulbs, and examine those previously set. All things liable to injury from severe weather, and which are requisite for another year, should be placed under protection without delay. Such as Fuchsias, Lobelias, Pelargoniums, shrubby Calceolarias, Salvias, Tiguidias, &c., will require this treatment. Modes of storing them away differ in different situations. Some can afford pits, some can spare even house room, and some are driven to the cellar. Whatever mode be adopted, let it be borne in mind that confined damp is nearly as prejudicial as frost. A lean-to shed is a very good place, and plants with a ball of earth dried on them after the manner of Dahlias, will keep very well there, plunged in coal ashes, with the addition of an old mat and a little straw over the shed during very severe weather.

GREENHOUSE AND CONSERVATORY.

Some of the very earliest Chrysanthemums may probably be getting past their best, and should be replaced at once by something of a more showy character. Whilst the principal collection is in bloom, a selection should be made of the best and most useful sorts, for there are many worthless varieties in cultivation, and it is better to grow duplicates of the really good kinds than to retain such as are but indifferent, merely for the sake of having a long list of names. Be careful not to let

things in bloom suffer from the want of water. Give weak clear manure water to Chrysanthemums, Salvias, Camellias, &c., and use every means to keep specimens in bloom as long as possible. Damp and mildew are the great enemies to be guarded against in the greenhouse, and these must be sharply looked after, especially in the case of plants that have not well ripened their growth, and are in a rather soft state. If the former is troublesome it must be dispelled by means of free ventilation on mild days, using a little fire heat at the same time, and for the latter a dry airy atmosphere is the best preventive; but the plants should be frequently examined, applying sulphur on the first appearance of the enemy. Very little water will be required here at present, but the plants should be carefully looked over about twice a-week, so as to make sure that nothing is allowed to feel the want of it. If not already done have the plants tied with the least possible delay, for it is very difficult to tie a plant so that it will not look somewhat stiff and unnatural, and the sooner this kind of work is done the better the specimens will look when in bloom.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Mushrooms.—Lately the reasons were given why a bed should be made late in an open shed, and should be deeper than usual. We did not wish to wait long before the bed was fit for spawning, and made, as it was, chiefly of litter partly worked and sweetened, and covered with a slight layer of horse droppings, we had the material so arranged that we could have a regular mild heat to permit of spawning early. The bed would not average more than from 15 to 18 inches in depth, and the heat obtained was not very strong, and quite regular throughout, but we had to wait fully three weeks before the heat was mild enough for the bed to be spawned. To gradually lower the temperature sooner we had the surface of the bed made as firm as possible, and a little earth thrown over it, but still the heat kept quite regular, but fully 10° higher than we would wish to trust the spawn in. We spawned at about 85°, and the heat continues very genial and uniform after the earthing-up—merely a few degrees less than the above, so that we have no doubt that the spawn will run well, and with covering, to keep cold from the bed, we think it will bear well. What we want to impress on the beginners in Mushroom-growing is simply this—that often they must exercise patience.

Not being able to use our Mushroom house, we should have liked to have spawned this bed a week or a fortnight earlier, but had we done so most probably the spawn would have perished. No doubt the close muggy weather rather put us out in the calculation as to time. In our younger days, under similar circumstances, and according to old customs, we should have bored the bed with holes to let the heat out. We have long regarded this plan as chiefly acting by wasting the strength of the material by letting air into the bed and causing it at first to heat more violently than if air were excluded. Much of the intricacy in such matters, as well as the whole theory of making up a hotbed to give a lasting heat, would be better understood if we would only recollect that a lasting heat is best sustained by admitting merely a small quantity of air to support slow decomposition: hence, frequently, when a bed becomes cold, turning it over when too close will cause it to yield a nice mild heat for a month or two longer. A little moisture will often do the same when the bed has heated itself dry: hence, too, the importance of not having the material too much decomposed before making it into a bed. It then becomes too close for air to get in, and cools. We have made beds in a very rough way in March and April, and they had not lost their heat in the following November. The most experienced, however, will often be deceived, and thus we had to wait for the spawning of that Mushroom bed a fortnight longer than we expected.

Cucumbers.—The plants we put in frames and in hot-water pits early in spring are still bearing, though now coming more weakly. Those in frames have merely had the frames banked-up with litter, and the plants are much stronger than those in the hot-water pits. The beds were made large at first, and with the exception of the banking-up they have had no lining. If we did not want the frames we feel sure that adding a good lining to the depth of the bed would cause them to continue for some time, as that would throw in more bottom heat, as well as secure an atmospheric temperature of from 60° to 70°. These plants had their roots confined at first to about the third

of the width of a 6-foot frame. In the course of the season they received some rich top-dressings, and the surface roots were allowed to run all over the soil in the frame. In the pit the place for soil is about 3 feet in width, the width of the pit 6 feet. There is a sunk pathway behind, the soil is put in front, and the plants are trained about 15 inches from the glass. As we wanted fruit early—that is, as soon as possible after planting, we did not turn out the plants into this narrow pit, but placed them singly in large pots, and then packed round the pots some sweet hot tree leaves. As the plants grew they were earthed-up, and the leaves were covered several times with rich compost, until early in summer the pots were hidden and the roots running into the surface of the narrow bed. We know no better plan for quick fruiting, and then continuous fruiting from the same plants. Even these plants are now to us the subjects of a little anxiety. We have fruited them heavily of late, expecting to want more Cucumbers than we did, and now we would remove and plant afresh, but for the likelihood that many fruit might be desirable a fortnight or three weeks hence, and we should not like our strong young plants to fruit under six weeks. We have five of these lights in this position, and we can hardly give justice to the young plants where they stand. We have three lights planted in pots as described above and growing nicely, but from these we take off every young fruit as it shows itself, for we well know that if young plants bear freely in the dark short days of November, it is of little use to expect much from them at Christmas and the new year, and in the following months. Even young plants in spring are injured by much early fruiting, but not in comparison to what they are in November and December. We have known cases of unpleasantness, because with every advantage plenty of fruit would be obtained up to Christmas, but few or none for parties after the new year. There is a great advantage in span or steep-roofed houses over flat pits, keep the glass as clean as one may; but even under the most favourable conditions, plants that bear heavily before Christmas will not in general be so fruitful and healthy afterwards.

FRUIT GARDEN.

We are sorry to say that though Apples promise to keep pretty well, Pears with us are not only earlier than usual, but are keeping but badly. Many Marie Louise, Louise Bonne of Jersey, Beurré Bosc, and Beurré de Capiaumont, when changing nicely became at once like a mass of jelly. Could this be owing to the excessive dryness, followed by the warm rains and muggy days of the autumn, and to the very rapid growth so late in the season? Of the sorts alluded to, and others, we have had fine well-flavoured dishes, but we have lost, and quite suddenly, too, more than we ever recollect doing before. A very short time elapsed between the time that they were scarcely ripe enough for the table, and the time when they were too far gone to be of any use. The fruit room requires more attention in sorting out all spotted and decaying fruit than usual.

Planting, as previously stated, cannot be proceeded with too early now, as the leaves and wood are ripe enough to permit of the roots being moved. In all cases where the growth is too luxuriant, a little root-pruning, so as to cut the perpendicular roots will be useful. Shallow planting and surface mulching will, however, in general, induce enough of fertility without the necessity of root-pruning; and with even a moderate recourse to summer-pinning, we are persuaded that low horizontal cordon training, when once it becomes more general, will pretty well render tree-lifting and root-pruning, to insure fertility, unnecessary. In planting favourite fruit trees, a few barrowloads of fresh manure will ever be an advantage.

Strawberries in pots we have protected from the drizzling wet. We hardly know as yet how we shall secure them for the winter. We lost many of the best plants last season from rats and mice. The most tempting baits seemed to be of no use as long as there were the crowns of the Strawberry plants to go to. Singularly enough plants in the open ground were not touched, or but little.

Vineries.—We looked over late Vines to pick out any diseased or, rather, spotted or moulded berries. We kept a little fire, with air on, every day, and leave a little ventilation at night when not frosty. As, unfortunately, most of the roots are in the open ground, we covered the border of the late viney with litter to keep the cold out, so that the leaves may be encouraged a little longer, and likewise covered the earlier borders with litter to prevent the heat of the ground escaping, as it is much more easy to keep heat in the ground than to beat the soil at an early period after it has been thoroughly cooled by

frost. A foot of litter or fern will be more safe and effectual now than more than double the quantity of fermenting material in spring.

Pruning may be proceeded with as far as all the hardier fruits are concerned. Those who have the heart may destroy tom-tits now by placing poison in the places in deformed Pears, &c., left for them to peck. They have done but little damage this season, and have only come in to nibble fruit not worth housing. During the summer they well-hunted over the trees in search of even a stray green fly. We have seen them busy at 4 A.M. peeping anxiously beneath each Peach tree leaf.

ORNAMENTAL DEPARTMENT.

In order that the pleasure grounds should look well even at the beginning of November, the beds were all picked over—there being still a good deal of bloom—and the lawns mowed, machined, swept over, and rolled, along with the walks, so that all now for a time should appear fresh and flourishing. To effect this and save some of the more tender kinds of Geraniums, these were covered in the frosty nights at the end of the month with mats, removed in the morning before breakfast. Some of those which we wish to save we shall take up before this is printed. The general cleaning gave us a great advantage, as the tree leaves, short grass, sweepings, &c., thrown into a compact heap soon heated, and there, with a covering of more mellow sweet material, will give a nice bottom heat to many of the Geraniums we shall take up and pot. This bottom heat, with air at top and bottom of the sashes in moderate weather, will cause fresh roots at once to form, and when they are formed, and the bottom cooled by degrees, the plants will stand wherever they can be airy and the frost be kept out. Most of the finer tricolors and the variegated Geraniums do best when thus treated, and potted singly in small pots. The green and zonal-leaved sections do well in the same way, but may be kept treated in the faggot style lately alluded to, on the principle that vitality is merely preserved, but with little growth in roots or stems before March.

As the days are shorter and the sky more clouded we removed and thinned the festooned creepers in the conservatory, &c., so as to admit more light. We took most of such plants as Chrysanthemums in pots, if not into the conservatory and corridors, at least into places where protection could be given; also Cytisus, so that they might be well syringed, tied, &c., before going into their winter quarters.

In our cold pits we have put in our Calceolaria cuttings, as alluded to last week. If we have not much frost they would do exceedingly well any time this month—better, in fact, than if inserted in September or the beginning of October, for then they would, owing to rooting earlier, require more care in winter. This muggy weather Auriculas in pots under a frame should have air back and front, but be carefully protected from rain and drip, which, especially the latter, ruin so many fine plants. The surface soil should be frequently stirred to keep all sweet, and this will be helped with a dressing of rough dust charcoal, not fine. If the pots are plunged the plants will need little or no water until spring. Carnations and Pinks which are potted cannot have too much air in mild weather, but they, too, need little moisture, and should be protected from heavy rains. If the pots stood on a moist bottom, that would be enough.

Violets.—We took up a lot of Neapolitan Violets, Czar, and other kinds, and placed them in rich, fresh soil in a cold pit under glass. We would have done this sooner, but during the hot weather, and our great shortness of water, they were much infested with the red spider, even though to keep them alive we shaded them with evergreen boughs. We found out that the spider did less harm where green spruce branches were used for shading. What with our pickings, syringings, and the rain and the cool nights, the plants that had scarcely a healthy leaf are now clothed with green foliage, and are well studded with bloom buds. In taking up the Neapolitans with good balls every bit of runner was removed, as runners never produce blooms in the current season, and exhaust too much the main stool. This is advisable when room is scarce under glass for other kinds, but is less essential with them, as the runners often produce good flowers. Though it is hardy enough, we always like to have some of the Czar under glass, for though the blossoms are single, they are large, very sweet, and carried on long footstalks, so that the flowers can be used for many combinations without the necessity of twiggings or wiring them. The length of the footstalk alone is a great advantage. In lifting such plants they should be well cleaned previously, and not a single discoloured leaf left. They soon made a return

for the care and the glass protection. A month ago the hardier Violets were plentiful out of doors. The colder weather has made them more scarce.

Eparises and Ericas still in cold pits must have plenty of air, that the latter, especially, may be safe from mildew. They and the more tender greenhouse plants will be better grouped on the stage of the greenhouse, for they can have plenty of air without noduly lowering the temperature, and much more direct light than they can have in a pit with the light chiefly above them. The more tender greenhouse plants, though having plenty of air, should not stand in a keen draught. Cicerarias and herbaceous Calceolarias, provided they have plenty of air and are safe from frost, cannot well be kept too cool and moist. Were this matter better attended to insect-covered plants would be more rarely seen, and scores of pounds saved in the matter of tobacco-smoking. Even in our plant stoves we should proportion our heat somewhat to light. Many plants will enjoy now comparative rest. Begonias, Eranthemums, and Justicias in full bloom or coming to it, will relish weak manure water. Ferns should never be quite dry, and when growing freely should be kept moist. Such showy plants as Poinsettia pulcherrima, and such useful plants as Euphorbia jacquiniiflora will set their bloom-buds better, and bloom better afterwards if from the end of October or the beginning of November they are kept dryish and a little cooler for a few weeks. When more moisture and heat are given the flowering will be better.—R. F.

TRADE CATALOGUE RECEIVED.

William Chater, Saffron Walden.—*Catalogue of Hollyhocks and Roses.*

TO CORRESPONDENTS.

* * * We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By doing so they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Books (*An Amateur*).—"The Vine Manual;" you can have it free by post if you enclose thirty-two postage stamps with your address to our office. (*A. McKillop*).—No new edition of the "Cottage Gardeners' Dictionary" is probable. You can have it from our office, including the Supplement, if you enclose 7s. 2d with your address.

Advice (*A Gardener*).—What next and next? "My master orders me in a bulging way to clean his boots and buckle on his straps and spurs, especially when the groom is out. The place is good, I do not want to leave. I should not so much mind about the boots, &c., if asked civilly, &c. What should I do?" How can anyone advise you better than yourself? We know some good gardeners now who cleaned boots and fire-irons too, and took out ashes in their first place. They found, however, as they progressed, that if they were to do much credit to themselves in gardening they must get out of the way of being general helper to Mary the housemaid, Molly the cook, and John the stable man, and they did so by moving to a place where the garden became their special charge. A man who would rise must be obliging; but, as a general rule, where a gardener and a groom are kept, it will not ultimately be to the advantage of employer and employed that the gardener should be called upon to perform the duties of a valet or a groom. If we were to judge from composition and penmanship, we should say you are more likely to distinguish yourself by making one line or employment the subject of your study and consideration. Still there are many comfortable well-paid situations where one of the chief requisites is the being "generally useful." If that is distasteful, then, as a gardener, you should engage that your duties are to be confined to the garden. We do not see how you can make much alteration in your present place, unless you brought extra prudence and courteous determination to your aid. How is it that you are always so handy for the strapping and buckling business? If the house and stables are not quite close to the garden, almost in it, you need not be quite so near at hand. This we say, because we have known some men grumble at being asked to do to this and that, and yet would place themselves in the way so as to be seen and asked to do what they pretended they did not like. Be assured there is no such thing as having all the sweets and none of the bitter in any position. The hanging about halls and stairways in gentlemen's places has ruined many a young man that otherwise would have been a good gardener. The employer who has many servants will be best served if each servant has his distinctive duties, because then the servant must pay more attention to his separate duties.—F.

FEANS (*Filices*).—To help you to identify species, Hooker's "Synopsis

Filicum" will be best. This "Species Filicum" contains only a select few.

SILVER SAND (*C. G. S.*).—This consists of very fine crystals of nearly pure silica. It may be usually purchased of florists. It is dug out chiefly from pits near Reigate, in Surrey. The grey drift sand obtainable from the shallows of rivers is equally good for potting purposes.

TEMPERATURE ON THE CHRISTMAS EVE OF 1830 (*R. E. Ashford*).—At Chiswick the thermometer fell to 4° on December 24th, 1830, and on December 28th to 1° below zero; but in many places the temperature was much lower—for example, at Chatsworth—12°, at Highfield House—13° 8', at Saffron Walden—12°. It was not only the intensity, but also the duration of the frost that was remarkable.

ABNORMAL GROWTH OF STELLA GERANIUM.—Two plants of the above Geranium have put forth a crown and leaves from the centre of the withered flower-truss. Both plants are this year's cuttings. I should be glad to know if any of your correspondents have observed a similar occurrence, and if it is usual.—G. PIM.

GERANIUMS IN POTS (*Agnes*).—The plants being from cuttings put in this spring or last autumn, and grown in pots for late bloom, will not require pruning now, as they will for some time afford fine trusses of flowers; at least, have some such as you name, and we expect them to continue flowering the greater part of the winter. In February we shall cut them well in, and grow them on for summer flowering. There is no cause why they should not flower finely next season.

EVERGREEN TRAILER IN INTERMEDIATE STOVE (*Thos. W.*).—For covering a low wall in an intermediate stove, we know of but one suitable plant—viz., *Ficus repens*, and it clings to any substance with the tenacity of Ivy. It is of free growth and very neat.

SOIL FOR SWEET-SCENTED VERBENA (*Young Gardener, Dublin*).—Two parts of common garden soil mixed with one part leaf mould, or the bottom of your wood-stack. The soil beneath the stack is not peat, but nearer in composition to leaf mould—that is, leaves thoroughly decayed and friable.

VINES FRUITING IN POTS (*Inquirer*).—As you intend fruiting them in pots two or three years consecutively, we should at once place the Black Hamburgh in a pot 18 inches in diameter, and prune it to a length of 6 feet; but we think it would be of little value for future years' bearing unless you are content to take no more than half a dozen bunches from it, and grow it in a house, not starting the Vine into growth before March. Place the Royal Muscadine in a 15-inch pot, and cut it back half its length. Two bunches would be quite enough to take from it next season. In potting be careful not to injure the roots, but loosen the sides of the ball. Provide good drainage, and cover it with about an inch thick of half-inch bones. You will need to give top-dressings of rich compost, and afford liquid manure when the Vines are in free growth. Let the Vines make more shoots than are wanted for bearing, and allow each an extension of rod of about 3 feet. The shoots not bearing next season will give vigour to the plants and aid in perfecting the crop, whilst they will be better suited for bearing another year than those fruiting next season.

PRUNING VINES (*C. N. B.*).—When the leaves have fallen, or by the middle of December, prune them, the side shoots to two eyes, and that will dispose of all the laterals. If the Vines have rods in addition to side shoots, cut them to 3 feet if strong, or if only moderately strong to half that length. We imagine what you term laterals are the side shoots or spurs.

VINE PLANTING (*J. R. G.*).—Plant the Vines now.

VINE ON OPEN WALL (*R. T. S.*).—You would treat your Vine more safely if, instead of removing it, you placed glass over it where it stands; then you would be sure of a well-ripened crop. Of course, you could remove it by carefully lifting it now, and planting it where it would be under glass, but as it has been planted ten years, you would require to lift it with great care, and then, perhaps, you would have a great return from it for a year or two. A cheap fixed lean-to roof over it where it is, would be the surest as respects returns.

VINE-ROOTS DYING (*J. W.*).—We can assign no reason for the roots of some of the young Vines dying, whilst others are so healthy.

REPOTTING A DICKSONIA (*Idem*).—A Dicksonia, if fresh top-dressed, may remain some years in the same pot; but it will be all the better if the drainage be seen to, and the most exhausted soil removed.

POTATOES AND MANGOLD WURTZEL (*H. R.*).—As you have but one field, and wish to grow no other crops than the abovesaid, your best plan will be to divide the field into two parts, and on the part which has borne Potatoes let Mangold Wurtzel be grown the next year, and vice versa. As you have a good supply of manure, you need not fear having deteriorated crops if you thus crop alternately.

KIDNEY BEAN CULTURE (*A Subscriber*).—We do not see in what way we can improve on your system of cultivating the Scarlet Runner Bean; but we should sow by the first week in May in rows 6 feet apart, with the beans about 6 inches apart in the rows. The ground intended for them should be well and deeply dug or trenched now, giving a liberal dressing of manure. In summer they should be well supplied with water and liquid manure in dry hot weather. We like them staked, but you may have them dwarf by repeatedly stopping them at a foot high. Make another sowing at the end of May. In our "Kitchen Garden Manual," which you can have by post if you enclose five postage stamps with your address, you will find full details.

FRUIT TREES (*A Cottage Gardener*).—You may grow the Black Hamburgh or Royal Muscadine Grapes in a ground viney, either on an east or west wall, but they would do much better in an open but sheltered situation—indeed, it would be a waste of wall to no practical purpose; besides, whichever wall you were to have, the ground viney against it would lose the sun's rays one-half the day, whilst in an open situation it would have the full benefit of the sun. As regards the fruit border, you may plant the Roses 6 feet from the walk, or 11 feet from the wall, but as you wish for fruit we would not do so, but at that distance from the wall we would have a wire put down a foot high, and 3 feet from that a row of bush or pyramid Pear and Plum trees, and 2 feet from that again another wire at the same height as the other. Both the wires we would use for Apple trees trained as double cordons. They may be planted 12 feet apart, and the pyramids or bushes 6 feet apart. You will have 5 feet left

between the second line of cordons and the wall, and that you must not cover with fruit trees, though there would be no objection to a row of Strawberries at 3 feet from the wall. Three good sorts are Sir Joseph Paxton, Keen's Seedling, and if you want a very early one, Black Prince. Unless you procure plants in pots, by planting ordinary runners now, you would not have much prospect of fruit next year—indeed, we would not plant before the middle of February. "Fruit Gardening for the Many" will suit you. It may be had post free from our office for five postage stamps.

HEADING-BACK NEWLY-PLANTED PLUM TREES (Inquirer).—In all cases we advise that newly-planted trees should be headed-back, but as a rule we would confine the operation to the central parts, or where more shoots are required for covering the space. The heading-back may be carried too far, and when a tree has good roots it is not necessary; but if the shoots are thin it is necessary to cut back, so as to secure the requisite number of shoots at the required part. We have seen shortening the central shoots only practised with good success.

PREPARING GROUND FOR POTATO PLANTING (N. C. H.).—Dig the ground to the plow, and throw it up as roughly as possible for the winter, giving whatever manure is required. In digging see that all grass, weeds, &c. are put at the bottom of the trenches. In February turn the ground with a fork, picking out any root-weeds, as Couch-grass, Dock, and Dandelion, and clear them off. If no manure is given at the first digging it should be spaded at the second digging; but whilst at the first digging the manure may be used in a fresh state, at the second it ought to be partially decayed, or what may be termed short, so as to dig in well when spaded on the surface. For a light soil Lapstone and Early Oxford Potatoes are excellent.

PREPARING MANURE (Idem).—We would free the stable litter of the short dung, and place it in the piggery until it became thoroughly wet, then we would remove it to a heap and let it remain until quite rotted—that is, until it could be dug in with a spade. It would be better, however, to take it direct from the piggery to the ground and at once dig it in, but in some cases this is impracticable. Dung usually takes six or eight weeks to become fit to be dug in with the spade, and then it requires to be turned over and wetted twice or thrice. Night soil is a capital manure. It may be mixed with an equal quantity of dry soil, and may be used fresh. A dressing an inch thick is not too much at this season, or half that in spring. Johnson's "Science and Practice of Gardening" contains what you require. It may be had at our office for 3s, or free by post for 3s. 4d.

CANKER (C. R.).—It is not caused by frost, and to remove the bark would kill the trees. If the Apple and Pear trees are young, the canker may be caused by the roots descending into an ungenial subsoil. Removing those roots, and keeping the surface mulched, may check the disease.

PEACH-HOUSE VENTILATION (New Forest).—We should be quite satisfied with your ventilation, but a small triangular opening at each end would be an improvement—say a triangle of from 24 to 31 inches on two sides, with a base 1 foot or so in length. Three or four openings in the back wall, near the bottom communicating with the open shed behind, would also be desirable—say 2 feet long by 12 inches wide. These would be advantages, but with early air-giving we would be content with the present ventilation.

PYRAMID APPLE AND PEAR TREES FOR NORTH-WEST OF ENGLAND (W. N.).—*Dessert Apples:* Early Red Margaret, Kerry Pippin, Cellini, Cockle Pippin, Margil, Nonesuch, Sykehouse Russet, Braddock's Nonpareil, Cox's Orange Pippin, Searlet Nonpareil, Adam's Pearmain, and Wyken Pippin. *Kitchen Apples:* Keswick Codlin, Lord Suffield, Cox's Pomonio, Afriston, Bedfordshire Foundling, Northern Greening, Dumelow's Seedling, Bleenheim Pippin, Hawthornden, Winter Majetin, Norfolk Bearer, and Rymor. *Dessert Pears:* Bergamotte Esperen, Beurre d'Amant, Louise Giffard, Beurre Hardy, Comte de Lamy, Alexandre Lambert, Louis Bonne de Jersey, Williams's Bon Chretien, Zephrin Gregoire, Ne Plus Meuris, Beurre Diez, and Jean de Witte or Glou Morceau. *Baking or Stewing:* Catillac and Verulam.

DATURA STRAFOLENS (Idem).—That is the name of the plant you describe. We cannot account for its flagging, except from its not being sufficiently supplied with water, or you may have destroyed its roots by an overdose of liquid manure. Your treatment must be good for the plant to bloom so well, and we do not perceive in what you used advice.

GLOU MORCEAU PEAR (W. H. H.).—It is a hybrid name, *GloU* is Flemish, and synonymous with our word *daisy*; *Morceau*, a morsel, is French; so that in entire English the name is the "Dainty-morsel Pear."

BOVINA POTATO (C. P.).—You will see the information you ask for in the notes from those who have grown it published by us.

OVERHANGING TREES (A. C.).—You should first request the owner of the trees to remove the branches which extend from his ground and overhang your garden. If he neglects so doing, then give him a legal written notice that you will cut them off so far as they do overhang your garden. If you do so cut them off, then place the portions removed in your neighbour's ground.

GROUP OF TREES IN PARE PLANTING (J. B.).—We would plant the group in masses—that is to say, at the two ends we would have about a dozen of the pink and the common Horse Chestnut, and in the middle two groups of Purple Beech, consisting of about an equal number of trees; the centre we would have Lime and English Elm, and the divisions between the masses *Pinus austriaca*, *P. Laricio*, and Scotch Fir, all at 12 feet apart. We would then fill up the part where the evergreens are with deciduous shrubs for mid-growth, so as to make them 4 feet apart—Black Thorn, Dentia scabra, Scarlet Dogwood, Ribes sanguinea, Snowberry, Gaelder Rose, and Sweet Briar; and the part planted with deciduous trees we would fill up with evergreen shrubs, as *Berberis Aquifolium*, *B. dulcis*, *B. Darwinii*, Tree Box, Holly, Yew, Laurastans, Evergreen Privet, common Laurel, and Rhododendrons. The spring is the best time for thinning out Larch.

ROYAL HORTICULTURAL SOCIETY.—We have received a very handsome bunch of Achurian Grapes from Mr Wells, of Southend, similar to those shown by him from a ground viney before the Fruit Committee on the 2nd inst., and which received a special certificate. By a slip of the pen they were referred to as Black Hamburgh in our report at page 348.

SELECT CHRYSANTHEMUMS (C. Montgomery).—See reports in another

page. If burnt in sufficient quantity to heat the house the plants would be injured. We cannot name florists' flowers.

BORDER RE-ARRANGING (A Subscriber).—In so narrow a border as 4 feet, we do not see what shrubs you can have except against the wall, and in addition to *Pyracantha* and *Pyrus japonica* which you name, we would advise *Berberis Darwinii*, *Cotoneaster Simonsii*, *C. microphylla*, *Forsythia suspensa*, and *Lignstrum japonicum*. Two feet from the wall we would have a row of Roses, and then perennials in front, re-arranging and planting those you have, or you might keep the space for annual hedging plants, but these you could arrange in beds on the lawn. We would stop up all the shrubs in the border, and trench the ground well before planting, giving a good dressing of manure. The shrubs should be planted 4 feet apart, and nailed to the wall.

ROSES—L'ENFANT TROUVÉ (C. W. D.).—*L'Enfant Trouvé* is very like *Elise Sauvage*, but has no synonyms. It will be found in the catalogue of Mr. Cranston, King's Acers, Hereford, and Messrs. Paul & Son, Cheshunt. It is not so hardy or so free-flowering as *Gloire de Dijon*, still in many situations it is a desirable Rose, but in general requires the protection of a wall. It is a useful Rose for pot culture, for spring forcing, though among the yellow Tea Roses for forcing, there is none much better than the old *Vicomtesse de Cazes* and *La Boule d'Or*. *Louise de Savoie* and *Souverain d'un Ami* are also especially good Teas for pot culture.

PYRAMID APPLE AND PEAR TREES (A. W.).—The soil is wholly unsuitable for Apples and Pears. Take it out and replace it with good strong loam. *Dessert Apples:* Red Astrachan, Kerry Pippin, Cellini, Sykehouse Russet, Cox's Orange Pippin, Cockle Pippin, orvunstein, and Searlet Nonpareil. *Pears:* Beurre Giffard, Williams's Bon Chretien, Comte de Lamy, Alexandre Lambert, Louise Bonne de Jersey, Zephrin Gregoire, and Bergamotte E-perou. A good winter Pear for a west wall is *Glou Morceau*.

POTATOES SPROUTING (Negro Novis).—The Early Rose and Mona's Pride now sprouting we would keep in the light if we could, and as cool and dry as possible, and if they are more sprouted than a quarter of an inch, it would be well to rub the sprouts off. The beginning of February is quite early enough for them to begin sprouting; but this year our Potatoes, especially the early sorts, are sprouting, no doubt owing to the drought of the past summer stopping their growth and inducing premature ripening. The cooler they are kept, if safe from frost, the better. If you give them to the pigs it is likely you will not receive for planting any that have not had the first sprouts removed. Those which have not sprouted are to be preferred.

AIR IN HOT WATER PIPES (B. A.).—You had better have an air-pipe in the return-pipe as well. With an air-pipe on the top flow-pipe, and the supply-pipe 2 feet above the flow-pipes, we cannot conceive how the water does not heat and circulate in these upper flow-pipes, except that the air-pipe is not at the highest point, or that the air-pipe is clogged or closed up. Two years ago we had a pit with pipes rising about 8 inches to the farther end, with an air-pipe there going outside, and then turned downwards to keep dust out, but some earth-bees had taken up their abode in it, and no heating nor circulation could be obtained until the small air-pipe had been cleaned out. We think this is most likely the reason. We could hardly assign any other cause, without knowing all about the levels of the pipes.

HEATING A CONSERVATORY (L. G. M.).—If the house, 17 feet high, has much glass at the sides, you had better have three pipes all round beneath the pathways instead of two. As these pathways are to be of ornamental tiles, there should be ornamental gratings to let the heated air freely up. A tubular boiler fed from the top is, perhaps, the most easily managed. A No. 2 of Messrs. Weeks's, costing from £5 to £7, would suit you. For our selves we would not look askance on a good saddle-back as that of Jones, 20 inches in height, 18 wide, and 24 long, costing about £6. For such a position we would prefer the pipes being jointed with iron flings and sal ammoniac.

GLAZING A CONSERVATORY (Reader).—We would in your case, if the glazing at the sides is done in the usual way, and the glass held firmly with putty, have the roof glazed with small laps—say of one-eighth of an inch. The plan you propose of having the glass put edge to edge without laps would answer very well, if by grooves deeper than the glass, and using yielding material for packing, you gave room for the glass to expand and contract laterally. If the glass is put rather firmly between rebate and rebate, or if the putty becomes so hard as to prevent its expanding at the sides, the closer and nearer the edges of the squares fit each other, the greater the danger of cracking from expansion. You will be safer by not having the glass quite close to the rebate on each side; still, even that help will not prevent the glass chipping at the edges. This expansion provided for at the sides, there is then little danger of chipping, and if the roof is not flat there will be no danger of drip.

NAMES OF FRUIT (A. Walker).—1, Betty Geeson; 2, Bull's Golden Reinette; 3, Figue de Naples; 4, Urbaniste. (A Constant Reader).—*Apples:* Springrove Codlin; 2, Piles Bussel; 3, Lamb Abbey Pearmain; 4, Christie's Pippin; 5, Huothou; 6, Russet Pearmain; 7, Kingston Black; 8, Golueu Reinette; 9, Casseler Reinette. *Pears:* 1, Brughnam; 2, Van Mons Leon Leclerc; 4, Passe Colmar. (H. C. Tonbridge).—1, Beurre Deroumeau; 2, Delanoy; 3, Comte de Lamy; 4, Old Colmar; 5, Winter Nohis; 6, Glou Morceau; 7, Princess Charlotte. (W. R.).—1, Braddock's Nonpareil; 2, Stormer Pippin; 3, Winter Hawthornden; 4, Cox's Orange Pippin; 5, Stead's Kernel; 6, Normanton Wonder. (A Constant Reader, J. W. M.).—1, Pearson's Plate; 3, Couri-Pendur-Flat; 4, Marmalade Pippin; 7, Braddock's Nonpareil; 9, Like Cox's Orange Pippin; 10, Api petit; 11, Carel's Seedling; 12, Broad-eyed Pippin; 13, Selwood's Reinette. (Centurion).—1, Kentish Codlin; 2, Reinette Blanche d'Espagne; 4, English Codlin; 5, Duchesse d'Angoulême; 6, Lemon Pippin; 8, Bedfordshire Foundling. (Cavendish Richardson).—1, Barcelona Pearmain; 5, White Nonpareil; 16, Court of Wick; 31, Sykehouse Russet. (A. D. R.).—When we omit naming some of the specimens sent, it is because we do not identify them. We knew your No. 2 to be *Duoyennu Comice*, but did not recognise No. 1. If you will send another specimen we will endeavour to name it.

NAMES OF PLANTS (Old Subscriber).—We cannot identify plants from their leaves only. (A. L. Richmond).—1, *Achimum Capillus-Veneris*; 2, *Lactuca dilatata*; 3, *Pteris serrulata*; 5, *Ruscus Hypoglossum*. (A. Y.).—We cannot undertake to name florists' flowers, nor plants from mere leaves, and you have sent both; 3, is *Euonymus europaeus*.

POULTRY, BEE, AND PIGEON CHRONICLE.

AWARDS—TRIMMING.

I THINK Mr. Hewitt replies to my observations rather in a hurry, or at least without my remarks before him; he has, at all events, altogether mistaken the drift of what I have written; and as no one knows better than he does that friendly discussion is the way to elicit truth and weed the errors out, I will return, with your permission, to his comments of last week on my remarks in a previous number.

He speaks only, for instance, of the difficulty of placing in order of merit all the "highly commended" pens; but if he read my remarks again he will see that my chief suggestion was for a distinct award to be given to all pens, and to those only which in an ordinary competition, or by intrinsic merit, deserved a prize. That was the point on which I laid stress, and on which I wished to ask his opinion, and on this he says nothing. The award I suggested was "very highly commended," but a perusal of the New York schedule has suggested to me that "diploma" would be shorter and better. I admit the force of what Mr. Hewitt urges in the one case, but he will not deny that while strict order of merit may present difficulties, as I admitted, by giving up that order in the simple commendations, his experienced eye would readily pick out the deserving pens at least; and my object was not so much to have in strict order the commended pens as by some systematised award, costing nothing, between prizes and commendations, to show by the prize list alone the character of a competition. In this way a number of diplomas in a class would show that the prizes were hardly won against formidable competitors. To attain this object they should not be given to merely good pens, but solely to such as are really worthy of a prize.

I again commend this matter to consideration, but this time more especially to committees. The cards might read thus: "HONORARY DIPLOMA, to certify that in an ordinary competition this pen would be worthy of a prize." They ought not to be too freely given; but rightly used, would not only give valuable information, but would make a show popular, please exhibitors, and place shows which cannot afford four prizes more on a level with the larger ones.

While I think this matter might be of great use, I am not spending "money" upon it, nor did I "admit," as Mr. Hewitt too hastily says, that I spent "time and money fruitlessly" a year ago upon trimming. I simply said my application to "Birmingham" had been made in vain. That show is never won over to anything all at once, and I do not despair even of Birmingham by-and-by; but with the general results of my labour I am abundantly satisfied, and the best proof of it is that I am yet, as opportunity offers, spending more. Briefly, I may say that bad cases of plucking are now at least passed by in about half the number of instances, whilst formerly they nearly always won. I may also add that about two-thirds of the schedules now contain a trimming clause, whilst previous to the discussion not one in ten contained such a thing. Bristol was one of the first shows to adopt one, and was copied by London, whilst some few (as Ipswich) have adopted Mr. Hewitt's own proposal to disqualify all the pens of an offender. Such are the more tangible results, but other fruits are no less real because less visible. There has been a growth in the fancy to some small extent of a "conscience" on the subject. I could name a "reverend" sinner whom the discussion led to abandon the practice, and a well-known Game Bantam breeder, formerly a notorious offender in the very worst form, who showed his birds, I believe, for the first time after the discussion, "without trimming a feather, sir;" though I am glad to add it was not his last appearance in that character. Better still, the real "fanciers" have begun more and more to find each other out, and to trust each other, while they have learnt to regard the cheats with a deep and pitiful scorn which was hardly known formerly, and which, I trust, if it go on, will yet make it apparent that treachery, though it may win, does not pay. The fancy "tailor" may still take his "borrowed rags," and by shameless plucking make them into a first-prize Brahma; but after long months of work that has been little apparent, and I am free to confess has given me many disappointments, I really do believe the time is at hand when he shall find that prizes so won are no real gain, but simply bring him the contempt he deserves. I never worked at this matter, despite of appearances, with more hope than I do now; and even

Mr. Hewitt will, I think, admit that there is some difference, however small, between the present time and two years ago.

It is a good opportunity to say that all who hate trimming may do their part entirely independently of committees or judging. Make the sinners feel you despise them; and as a man who can cheat in one way will do so in another, never deal with a known trimmer. The worst, or one of the worst of them, I know, is also a man who sells eggs which hardly ever hatch. If all who really do hate the fraud would show it, we should soon have the fancy cleared of those who do not really belong to it, and have no real love for it, but are in good truth only its scum.

Finally, I think Mr. Hewitt has, I am sure not knowingly, done injustice in saying that some of the very first on the list of protestors against trimming proved among the very earliest to be "caught for actually sewing through cocks' combs to keep them upright." Every protestor, as I was quite prepared to find, has not proved immaculate; and it must also be remembered that many exhibitors are in the hands of their men, and know little of their fowls themselves. Still, as a matter of fact, I do not remember any protestor having been guilty of the enormity referred to, and I should be glad if Mr. Hewitt could give the instances. The only name I remember is that of one who stained the wing of his Cochon cock, and in this case it was I myself who publicly stated him to be a "protestant." "One" is not "some," and as I know at least the main body of the signatories to have been honest in the matter, I feel I am only defending them in asking Mr. Hewitt to mention the "some" cases he refers to. My belief is he has mixed up in his mind my identification of the sinner in question with some other case; if it is thus, I feel sure no one will feel greater pleasure than he that it should be so. The object of neither of us is to injure private character, and as what took place between us some time since I am quite willing to confess enlightened me somewhat as to the difficulties of a judge, so I am sure he understands me too well now to put a false construction on my defence of honourable men.

He has a passing remark on judging, by the way, which is worth its weight in gold, but which I must leave for a future occasion.—L. WRIGHT.

INCREASE OF NUMBERS OF PRIZES—
JUDGING.

AMONG the many obligations due from all fanciers of poultry to Mr. Hewitt, must be reckoned the fact that he is not unwilling at the proper time to speak out, or to let us know what he thinks upon the various questions that arise in the poultry world. We are, indeed, fortunate to have a judge among us whose unswerving integrity is only equalled by his capacity for his peculiar work, while at the same time he can put his thoughts on paper in a manner calculated to adorn the pages of any journal to which he is disposed to contribute.

When I read the suggestion that all highly commended pens should be placed in order of merit, I thought that no judge would ever consent to add such a burden to labours which at present are by no means light, and it is evident that Mr. Hewitt, for one, will not accept the proposal. The gain to the public, in fact, would not in any way compensate for the additional trouble imposed upon the judges. And yet I am glad the matter has been mooted, because Mr. Hewitt has now told us what he thinks the best rule with regard to the distribution of prizes—that it would be well if possible to have four prizes in every class instead of two only, or at most three. This suggestion I regard as of great importance. Let me give an instance from my own experience. I had intended to have exhibited both at Southampton and at Ipswich. Looking over the schedules of prizes offered, I find that there are two only in the classes in which I should exhibit, and although cups are held out to those who reach the very top of the tree, yet the prospect of a cup seems too remote to induce me to send my birds. Had there, however, been third or fourth prizes offered, I should at once decide to exhibit, for even a fourth prize is a higher honour than a highly commended, and, moreover, it helps to pay the expenses.

And now let me congratulate the Committee of the Crystal Palace Show on the improvement they have made in their prize list this time compared with the one of January last. It will be long before I shall forget the havoc that was made on the last occasion in the Dorking class among birds which had done great things when shown before, but which were then

compelled to be content with a high commendation, or a commendation only. There was then but one class for Coloured hens and pullets, and one for cocks of all ages. Now there are three classes for Coloured birds, three for Silver-Grey, and one for White. If the Committee next year will take Mr. Hewitt's hint, and give four prizes in each class, they will probably increase the entries, and so improve the show. I trust, too, that they will find something better than those execrating wire pens—with wire I mean on three or four sides—in which every other minute the bird's tail is passing through or rubbing against the wire, so that a show of three or four days' duration is sufficient seriously to mar, if not altogether to destroy for a time, the exhibition prospects of many a fine bird.—E. M. E. A.

TO SOUTHAMPTON SHOW.

"Unto Southampton do we shift our scene."—(Shakespeare's
Henry V., Act 2.)

No. 1.

I propose to write two papers, the one to Southampton Show, the other at Southampton Show; the first dealing with generalities, the second with the specialities of the Exhibition.

Hampshire, Hants, or Southampton used to puzzle and annoy me when, not exactly yesterday, I was learning my English counties. Shropshire or Salop was bad enough to remember, but at least they both began with an S; but Hampshire, Hants, or Southampton was intolerable. What had Southampton to do with Hampshire? Then, soon after, I learned to connect Southampton with travelling to the far east, and this did not increase my love much, as friends, boyhood's friends, with whom I walked in our playground, the precinct of an old cathedral, "twinning arms round each other's necks as only school-boys can," to quote Dr. John Brown, had gone from Southampton, and fought and died in the Sikh war in the far India. So I had little love for the place, but I knew it not, and, as it proved, because I knew it not; and now, thanks to poultry, I have made the acquaintance of Southampton.

Leaving Wiltshire on Monday week with a mist around me was not encouraging, but unexpectedly meeting at my station a brother parson and brother poultry fancier put a brighter aspect upon affairs, and much mended matters. The day was indeed dull and dreary, but then could we not talk pleasant poultry talk, and then talk parson talk proper, and then hark back to poultry again? We did this on Monday, and though the mist hung over us we minded it not. Westbury White Horse stood out shaggy with mist, looking like a rough Shetland pony. Curious that we should have in Wiltshire three white horses cut on the downs—that on Cherrel Down, near Calne, this at Westbury, and the one the boys cut out at Marlborough, all better shaped than the original and far-famed one in the Vale of White Horse in Berks. Talk, talk, and no view until we come in sight of Salisbury Cathedral, and a long and good view of it we had as the train wound slowly out of the station. Does any reader know that most genial and kindly book of the American blacksmith, "A Walk from London to Land's End and Back"? If he does, he will perhaps remember Elihu Burritt's beautiful words about Salisbury Cathedral spire; but all will not have read the book, so I will quote them. Catching a distant view of it, he says, "Beyond, like a long delicately tapering finger, ringed at the middle joint, the spire of Salisbury Cathedral points upward, pushing its silver nail into the lower clouds. For six times the life-length of the American Republic that finger has been uplifted in sky, cloud, and storm. In the most tempestuous years of English history, in John's day, and Stephen's, and Cromwell's, it towered with steady poise into the still blue bosom of the sky, like a petrified human prayer, lifting the cross nearer heaven than it was ever raised by other shaft on this proud island." As I passed, and gazed and admired, I thought of these eloquent and graphic words. No one more noticeable thing until Romsey brought to mind Lord Palmerston's manly English character and career. Then on further, and amid red brick and blue slate, and a gleam of masts in the docks, I am at Southampton Station.

And now, to use Shakespeare's words (and he almost always will supply a suitable motto),

"Unto Southampton do we shift our scene."

Nowhere do old and new stand out in more direct and abrupt contrast than in Southampton. The town is very old and very new, but there exists a divider in the Bar Gate, an old gateway not unlike, but much superior to, Temple Bar. In speaking in Southampton it is "Above Bar" and "Below Bar"—below Bar all old, above Bar all new; below Bar trade, above Bar

private residences; below Bar much crowding of houses, above Bar all width of streets and spacious parks or park-like squares. In the old part crop out portions of the old stone walls mixed, and mingled, and built in to red brick houses, like warts on a hand, with this difference, that the warts are far prettier than the hand. In some parts of the Below Bar there are remains of ancient towers and military architecture. Above Bar is my temporary home. By the way, I always feel that a friend's house in a strange place is my home there, so different the feeling when in lodgings or at an inn; and never did I find kinder friends or feel more thoroughly at home than at Southampton.

The poultry show will not be opened until Tuesday afternoon, so I stroll about; and further Above Bar come upon one park, or, more properly speaking, large park-like square, called "Watts's Park," because a marble statue of the good little non-conformist Isaac Watts, D.D., a native of Southampton, stands in its centre. There, in gown and bands, and with hymn-book in his hand, stands he who was the best writer of children's hymns this country ever produced. It is said that on this spot, overlooking Southampton Water, and viewing the beautiful country beyond, Watts wrote the lines—

"Could I but stand where Moses stood,
And view the prospect o'er!"

and it is for this reason that the statue is there placed. On the pedestal beneath the statue are four bas-reliefs, the best a group of little children in the dress of the day, and in their midst the good little doctor and his hymn-book. Over this group are the suitable and true words, "He gave to lisping infancy its earliest and purest lessons." In another such park is a statue of Lord Palmerston, and in another one of some worthy Mayor of former days. Wide are the streets and well-built the houses in the part above Bar. I stroll by the Water, a beautiful long narrow estuary, with the New Forest beyond it, and I stand at the door of the Carlton Hall, which, I am told, is the largest room in Southampton, but no admittance yet; but of it and of its contents No. 2 shall, all being well, tell next week.—WILTSHIRE RECTOR.

POULTRY SHOW REPORTS.

First let me altogether disclaim any intention of inflicting a wound on "WILTSHIRE RECTOR" deep enough to require a plaister. The utmost I wished was to give him just the gentlest and friendliest dig in the ribs, and that, too, with no more dangerous weapon than the stump of my old quill pen.

"WILTSHIRE RECTOR" sets me down as a beginner. Certainly my experience is not so extensive as that of many, but at all events I can claim as long experience as an exhibitor as he can as your correspondent; and in those breeds in which I am most interested I think I know the points of a good bird without having to turn to the pages of the "Standard of Excellence" for information. Let me remind him that I did not ask for information as to what birds *ought to be*, but what they *are* at the particular show which is being reported—how nearly they approach to the perfection demanded by the "Standard." But at the same time it could not but happen that in such reports as I asked for much valuable information would often be obtained incidentally, which would do much towards setting at rest many at-present-debated questions.

"WILTSHIRE RECTOR" instances Mr. Blaketon's articles. I regret to confess that I am absolutely ignorant of Canaries. If I dared, I would say that the prizes seem to be awarded always to the ugliest birds. Nevertheless, I never pass over one of "W. A. B.'s" articles; they are indeed so witty, so much more than readable—so highly amusing. I have looked back to the report upon the Crystal Palace Show referred to by "WILTSHIRE RECTOR," and I perfectly agree with him that it is admirably done, but I entirely disagree with him as to its not going into details. Let "WILTSHIRE RECTOR" read it again. It takes each class separately; it picks out the best birds in each; it points out the characteristics of many of them; it mentions in a way which could not offend the susceptibilities of the most sensitive judge when he does not altogether agree with the decisions; in short, it is just what I have asked for in the reports of our poultry shows, and I hope "WILTSHIRE RECTOR" will take it for his model when he gives us his account of the next Bristol Show, which I trust he will be able to see and to write about, that we may have the pleasure of reading it.

I take it that reports of poultry shows are written for the benefit of poultry fanciers, to whom the much-abused details are

not dry; and therefore they should be different in style from those articles which are intended for beginners and to stimulate the love of our feathered pets. Let these be as elementary as you please, and as attractive as all "WILTSHIRE RECTOR'S" letters are; with which plaister I will leave the subject, after metaphorically shaking hands with "WILTSHIRE RECTOR," and hoping that we may live to meet at some time, perhaps at Birmingham or the Crystal Palace.

I intended to say a word or two upon our "Persian friend's" letter, but I feel that I have already tried your patience, Messrs. Editors, too severely.

Let me, however, ask just one question. I have had a copy of the *American Poultry Bulletin* sent me, with a schedule of the New York Poultry Show. In the schedule I see prizes offered for "White-headed Brazilian Divers," "White Crested Biarritz Ducks," and "Nicaragua Singing Ducks." These names sound very tempting—can you tell me anything about their owners? Are they domesticated or wild birds? And are they known at all in this kingdom? and if so, where are they to be seen or obtained?—SHROPSHIRE RECTOR.

[We published a woodcut and description of the Cayuga, which we believe is the same as the Nicaragua Duck, in the fifth volume of this Journal. Of the other squatics we know nothing.—EDS.]

THE NEW YORK POULTRY SHOW— LEGHORNS.

THIS Show is to commence on December 14th, and remain open till the 22nd. I fear such a long period of confinement will deter many British breeders from competing; but to meet the case as far as possible the Committee have arranged for a grand auction of the foreign birds, which, if of good quality, will be tolerably sure to realise fair prices, especially as they will be well advertised by the Society. The danger of a return voyage will by this means be avoided.

Compared with our English shows the arrangement of prizes seems very curious. Our exhibitors are always complaining they do not get enough in hard cash. Whatever would they say to the American system, which gives as four prizes in all the general classes a bronze medal, diploma, honourable mention, and high commendation respectively? so that the unlucky second may if he please exclaim, "All is lost save honour." Some silver medals, however, are also given, and in many other classes various poultry and Pigeon books form the prizes. For several breeds there are also silver cups varying in value from 10 to 25 dollars; and in particular, there is a cup each, value 25 dollars, for Dark Brahmas, Buffs, Grey Dorkings, and Houdans, to be awarded to the best trio of old fowls with six of their own chickens. A great gold medal, a second gold, and a silver medal are specially provided for the best collections of poultry from over the sea. The most valuable prizes of all, and which are open to English aspirants, are for the best essays on the breeding and management of poultry (prizes 100, 50, and 25 dollars), and for the best plans of poultry buildings (prizes 50, 30, and 20 dollars).

There is a class for Any other variety, but I do not know what is to go in it, for there are separate classes already for about every breed known, including even Creepers, Frizzles, Rumpkins, and Russians!

As a subscriber wanted to know the other day what Leghorns were, I may as well say it is a very favorite American breed just now coming over to this country. The most esteemed colour is white with, I believe, yellow legs and single combs; but many prefer a rose comb, which has generally pink or white legs. To judge by the engraving in my possession, no fowl could show stronger appearance of a Spanish origin, but the yellow leg makes it hard to say what cross has been employed. The rose-combed and white-legged breed is in my opinion crossed with the White Dorking; and that some cross has been employed is nearly proved by the fact that the other recognised colours are brown (with Grey Dorking?) and Dominique, which answers to what we call Cuckoo, the American Dominique fowl resembling our Cuckoo Dorking, or rather Scotch Grey. Be this as it may, the breed is fast becoming a favourite in the States, is hardy and a good layer, and is said by many to be more profitable than any other variety known in America. A very good pen of White Leghorns, I may as well say, was shown by Mr. Tegetmeier last week at Southampton, and I quite expect the breed will soon be well known in the Variety class at our shows.

A lot of odds and ends follow the poultry in the New York

schedule. Everything that ever was, is, or can be petted seems to be put down for a class. I really do not exaggerate, for they range from deer and ponies down to white mice. There is no end of classes for Squirrels; and such things as Ferrets, Minks, Marmots, Coons, Opossums, Chipmunks (what is this little beast?) and Spotted Gophers, all find a place. Being of an inquiring mind, I really envy those who can afford to visit the New York Show.

I will only add that I shall be happy to forward schedules to all who apply for them.—L. WRIGHT.

[The Leghorns shown at Southampton are noticed in our report to-day. In addition we add the following from *Moore's Rural New Yorker*. "The White Leghorns are said to be a hardy breed, and of medium size, of quiet disposition, persistent layers, of a pure white colour. Their legs and skin are yellow. The cocks have large single combs, which should be perfectly erect; full wattles, and large cream or white ear-lobes, extending sometimes upon their face, and not dissimilar to those of the White-faced Black Spanish. The hens have usually large combs, frequently seen to lop over like those of the Spanish hen. The young are easy to rear, feathering up soon. They are reputed to be excellent winter layers."—EDS.]

PURCHASED EGGS.

I AM an amateur breeder of Dorking fowls, and therefore desirous of improving my stock, and write to detail my experience in the purchase of eggs for breeding purposes; further, to inquire of my brother amateurs and your readers whether they have experienced similar disappointments. Four years since I procured a sitting of eggs from an eminent breeder, for which I paid, with carriage, 22s. 6d.; these brought no produce. Two years since I obtained, through a friend, a sitting from a great prizetaker in another county; these eggs all proved bad. This last season I obtained my eggs elsewhere—the result is two chickens only, which are neither Dorkings nor any other breed. Thus, I have expended nearly £4 in eggs, including carriage, and have two chickens, worth about 3s.—UNFORTUNATE.

SOUTHAMPTON POULTRY SHOW.

THE arrangements of this year's Show were promptly to time, careful, and well regulated. Those of our readers who may never have attended a Southampton show will be pleased to hear that the Carlton Hall, in which the Show is held, is one of the very best rooms that could be desired for the purposes of a poultry show, and the really excellent exhibition pens supplied by Mr. Billett, of High Street, Southampton, which are so large and lofty, left nothing to be desired on that score, even by the most anxious and fastidious amateur of poultry. The improvement as to the number of exhibitors, as well as to the number of pens entered, is a matter for general congratulation, as considerably over a hundred more were exhibited this year as compared with last. Again, as indicative of future success, at this meeting's public luncheon no less than seven silver cups and a silver watch were spontaneously offered by private individuals, altogether irrespective of the customary prizes given by the Southampton Committee, so that the continuance of popularity and success is well guaranteed. We must add to this, that the public attendance this year, the weather proving very favourable, exceeded that in any of the preceding eleven years this Show has been established.

The *Spanish* fowls, though generally somewhat out of high condition, were, as a whole, a very good class indeed; and the *Grey Dorking* classes, both chickens and adults, were far superior to any yet seen at a Southampton show. Mr. Martin's well-known Rose-combed Dorkings were among the prominent winners. *Cochins* were of first-rate quality, though many pens were wholly, or in part, much out of condition. Mr. Cattell's hen in the third-prize pen was one of the best exhibited for many years past, but was, unfortunately, mated to a cock in such indifferent health, as to throw her out of high position altogether. The *Light Brahmas*, as they always are at Southampton, were the glory of the Show, and the Rev. H. Maynard and Mrs. Williamson were entitled to their success in a very severe competition. The whole of these birds, in very extensive classes, proved at a glance how great the care and attention must have been to breed them so truly to feather as they were shown. Though a few pens of very excellent *Hamburghs* were shown, the majority of those competing in these classes were not so good as in former years. A number of pens of very first-class *Game* fowls were exhibited, in which the condition could not be improved, but, on the contrary, not a few others lacked both robust constitution, and, at the same time, purity of feather. A grand pen of adult Black Red Game fowls, shown by Mr. Gibson, ran in very closely for the President's cup, of the value of ten guineas. Except in the case of two or three pens of *Polish* fowls, we confess ourselves to be disappointed, the majority showing rather a falling off in quality than an improvement. A very great feature of the Show,

as might be fully expected in this locality, were the *French fowls*; for Houdans, La Flèche, and Crève-Cœurs were shown of the highest merit, and in numbers quite unprecedented. In the chicken classes for French fowls we cannot recollect so many pens being highly commended, or more deservedly so.

In the "Any other variety" class there was much merit, Black Hamburghs being first, and excellent Malays the second prize birds. In this class we cannot refrain from mentioning a pen of "Leghorns," a variety hitherto not seen in any public exhibition in England. They resemble very closely White Spanish fowls, but, which adds much to their singularity, they are as yellow in the legs and feet as a Malay fowl, and we are told they are as hardy as a Brahma, being also excellent layers. They are a breed introduced recently from America, and appear somewhat likely to be a very useful variety for general purposes in the farmyard, their powers of egg-production being extreme, and the quality of the flesh for table purposes, more especially when roasted, very closely approximating to that of Game fowls. The Game Bantam class was, though large, not so perfect, except the prize birds, as we might reasonably have expected, but the "Any variety of Bantam" class made the most ample amends. Sebrights were numerous and good, and Black Bantams and Light-feathered Japanese Bantams of the highest merit were shown.

To speak of the Aylesbury Ducks in detail would be needless for Mrs. Mary Seamons, of Aylesbury, heading the list with two pens, which would be very coveted in the eyes of any Duck-breeder. In the "Any other variety" class for Ducks twenty-four pens competed, of such quality as is but rarely seen. The Baenos Ayrean Ducks were exceedingly good. The Mandarins and Carolina were shown in exquisite feather, and besides these there were entered some first-class Rouens. We now come to one of the most remarkable features of the whole Show, pen 362, entered by the owner, Mr. F. G. Dalgetty, of Roke Manor, Romsey, as "Paradise Ducks." They were certainly very remarkable, perfectly tame, being, as stated in the catalogue, "bred in New Zealand." They consisted of six birds, apparently three of one kind, a pair of another variety and the odd one still different from either of the others. They were all shown (we had almost said crammed) in one pen, so that much difficulty ensued to those visitors whose desires prompted a close inspection. No one seemed to know anything about them among the numerous visitors present; in fact, the Judge himself candidly admitted "they were quite new to him," the reason, we suppose, they were "very highly commended," though the rule of the Show was distinct, that each pen should be a pair only. They naturally were one of the lions of the Show, but were entered at the reserved price of £1.0.

The *Geese* and *Turkeys* were perfect giants of their kind, and here Mr. Fowler and Mrs. Seamons were the recipients of the prizes in the first-named class, and Mr. Patton and the Rev. J. L. Ridley in that for Turkeys.

The entries in the Selling classes—one class for "single cock of any variety or age," and the other for "a pair of hens or pullets of any breed"—must have proved a most excellent "hit" for the coffers of the Society, as seventy-eight pens competed. In the cock class a Grey Dorking and a Crève-Cœur were the respective winners, and in the class for hens Silver-Grey Dorkings and Partridge-coloured Cochins were successful, among a host of rivals that would certainly have pretty well held their own at the majority of shows.

The *Pheasants* were shown in most excellent plumage, and added much to the beauty of the Exhibition. Strange to say, there was not a single entry in the class for "Ornamental poultry." We would suggest that another year the heading should be for "Ornamental birds of any kind," and we then think the entries would, as at Newcastle-on-Tyne some fifteen or sixteen years back, insure a most comprehensive and attractive entry, forming, too, a very pleasant break in the monotony of a poultry exhibition.

The table of dressed poultry, "trussed but not drawn," proved quite an interesting feature, Mr. Dowsett appearing in the van with fowls of excellent quality and very nicely dressed; some others, much heavier but coarser specimens, being entered against them. These table fowls were a cross between the male Light Brahma and Grey Dorking hen.

In the portion of the Show devoted exclusively to foreign and British birds, a pair of Nomidian Cranes, a really *Buff-coloured* Blackbird, and a most singular Mule, bred between a Bullfinch and common Linnut, were well worthy of attention. A pair of Palliated Jays from Mexico were also among the first ranks of novelties displayed.

Pigeons throughout were excellent, but several attempts at imposition by showing two cocks or two hens instead of a pair, very properly resulted in instant disqualification. The whole of this division of the Show (the Pigeons) occupying the orchestra, was seen to great advantage.

With such a varied amount of attractions, the satisfaction of the visitors was openly and very generally expressed. Although this eleventh Show of the Southampton Society was brought to so very successful an issue, thanks to the management of a thoughtful Committee and the never-relaxing efforts of Mr. Philip Warren, the Honorary Secretary, there is a little matter connected with the next year's prize schedule that admits of improvement. This year the President's silver cup, value ten guineas, is given to the best pen of poultry of any variety. Where so many of the first-prize pens are so nearly perfect, it is a thankless, invidious, and capricious task to adjudge this final

premium; and certainly were this valuable prize given to the exhibitor of the best collection of poultry, it would as surely increase the number of entries as it would improve also the quality of the birds throughout the whole Show. Mr. H. Yardley, of Birmingham, took both the extra cups for poultry and Pigeons.

Mr. Edward Hewitt, of Birmingham, judged the *poultry*; Mr. Esquiland, of London, the *Pigeons*; and Mr. Wilmore, of London, the *Canaries* and *Foreign Cage Birds*.

Further remarks on the Pigeons and a notice of the Canaries and other cage birds, of which a prize list is given beneath, will appear next week.

NORWICH.—*Clear Yellow*.—1 and 2, Moore & Wynne, Northampton. *rhe*, W. Walter, Winchester (2); T. Mann, Camberwell New Road. *he*, Toot & Cleaver, Kettering (2). *c*, E. Lidstone, West Cores; H. Apted, Worsthing; B. Wildsher, Hinchester. *Clear Buff*.—1, Moore & Wynne. *c*, Toot & Cleaver. *rhe*, W. Walter (2); G. Knock, Coventry. *he*, Moore & Wynne. *H. Apted*. *c*, G. E. N. Rawlinson, Gloucester. *H. Apted*. *Marked or Variegated Yellow*.—1, T. Mann. *2*, W. Walter. *rhe*, H. Apted (2). *he*, F. Hodding; H. Apted (2). *c*, T. Mann; Moore & Wynne (2). *Marked or Variegated Buff*.—1, W. Walter. *2*, Moore & Wynne. *rhe*, W. Walter; Moore & Wynne. *he*, T. Mann; H. Apted. *c*, G. E. N. Rawlinson; H. Apted; T. Wildsher. *Any other Variety*.—1 and 2, Moore & Wynne. *rhe*, W. Walter; Moore & Wynne. *he*, W. Walter; Toot & Cleaver; H. Apted. *c*, H. Apted (2).

↑ For the greatest number of points in the Norwich classes—Moore and Wynne, Northampton.

BELGIAN.—*Clear Yellow*.—1, T. Moore, Fareham. *2*, T. N. Harrison. *rhe*, T. Moore; C. Carver, Landport. *Clear Buff*.—1 and *rhe*, O. Nicholson, Landport. *2*, J. N. Harrison. *Variegated or Marked Yellow*.—1 and 2, O. Nicholson. *he*, C. Carver. *c*, Mrs. J. Chinery. *Variegated or Marked Buff*.—1 and 2, O. Nicholson. *c*, J. N. Harrison.

CANARY.—*Golden-angled*.—1, T. Fairbrass, Canterbury. *2*, J. Taylor. *rhe*, H. Ashton, Polefield Hall, Prestwich; J. N. Harrison. *he*, O. Nicholson. *2*, Fairbrass. *Silver-angled*.—1, J. Taylor, Middleborough-Tees. *2*, and *rhe*, O. Nicholson. *he*, J. Taylor; H. Apted; C. J. N. Harrison.

GOLDFINCH MALE.—*Jonque*.—1 and 2, H. Ashton. *he*, J. Baxter, Newcastle-on-Tyne. *Méale*.—1 and 2, H. Ashton. *rhe*, J. Baxter (2). *he*, J. Goodie, Leicester.

CANARY OR MALE (Any other Variety).—1, T. Mann (London Fancy). *2*, H. Ashton (Bullfinch and Goldfinch). *rhe*, E. Lidstone, West Cores (Cinnamon); H. Apted (Cinnamon); H. Ashton (Linnut Mule) (2). *he*, Miss E. Verrier, Brighton (Linnut Mule); J. Baxter (Siskin Mule).

BRITISH BIRDS.—*Bullfinch*.—1, J. W. Harrison. *rhe*, J. Jeans, Marchwood, Southampton. *he*, W. B. Bailey, Furbert; Mrs. Rowe. *Goldfinch*.—1, O. Nicholson. *rhe*, W. Walter. *c*, J. W. Harrison, Great Portland Street, London. *Linnut*.—1, J. Barker. *rhe*, W. Walter. *Siskin*.—1, J. W. Harrison. *he*, W. Walter. *Woodlark*.—1, J. W. Harrison. *he*, W. Walter. *Blackbird*.—1, J. W. Harrison. *Song Thrush*.—1, Mrs. W. Stowe. *rhe*, J. W. Harrison; W. Walter. *Any other Variety*.—1, J. W. Harrison (Nightingale). *2*, A. J. Hubbard (Magpie). *rhe*, J. W. Harrison (Starling); W. Walter (Dove-coloured Blackbird); H. Chamberlain, Bassett, Southampton (Magpie). *c*, J. Summons; W. B. Bailey (Starling).

FOREIGN BIRDS.—*Cockat* (Any variety).—1, C. Simeon, Hursley, Winchester (Longtail). *rhe*, W. B. Bailey, Furbert (Leadbeater). *Parrot* (Any variety).—1, J. W. Harrison (King). *he*, W. B. Bailey (Bulla Bull). *Lor. Zebra*.—1, E. Taylor. *rhe*, W. Walter. *he*, W. B. Bailey. *c*, J. W. Harrison. *Any other Variety*.—1 and 2, J. W. Harrison (Grass Parakeets and Cardinals). *2*, Mrs. Bailey (Witch). *rhe*, W. Walter (Madagascar and Waxbills); W. B. Bailey (Cardinal); Mrs. Bailey (Widow).

DERBY CANARY SHOW.

(From a Correspondent.)

THE thirteenth annual Exhibition of Canaries and other cage birds took place at the Athenæum, Derby, on the 5th and 6th inst. The first twenty-three classes were confined to members of the Society. There are fifty-five members, and amongst them are some of our best All-England exhibitors. I will just mention here that Mr. Bexson, the Honorary Secretary (and a more enthusiastic fancier I have never met with), has had the misfortune to lose nearly the whole of his valuable stock—a circumstance much to be regretted, and I am sure he will have the sympathy of every true fancier. For a valuable silver cup, offered by Mr. E. Bearnrose, for Crested Buff, equal points were gained by three members.

The following are the birds which are deserving of special notice:—33, Clear Buff Norwich, exhibited by Mr. J. Orme, rather above the average; 35, Marked Yellow, exhibited by Mr. Keys, is good in colour; 61, Marked Buff Norwich, shown by Mr. J. Orme, is a grand bird, and will be heard of again. 72, A. Upton, a good bird; 81, J. Marshall, a very fine bird, and it would have been first in the Open class. 101, Green Norwich (Yellow), G. Fisher, and 106, G. Fisher, Green Norwich Buff, were also fine; 114, Silver-spangled Lizard, S. Bunting, a bird that will stand well whenever exhibited. 123, S. Bunting, Mealy Goldfinch Male, was a very handsome bird, light, and evenly marked.

I will next notice those classes open to all England. I was surprised to find so few entries, as the prizes offered were exceedingly good, being £1 for the first, and 10s. for the second prize in the Norwich classes. In one class there was no competition. Clear Yellow Norwich, 111, W. Jerram, and 136, S. Bunting, were fair birds; Clear Buff, 151, J. Bennett, was a grand bird; 141, J. Prosser, was also a fair specimen; 154, Marked Yellow, was a fine bird, extra good in colour, and of good size; 162, W. Jerram, is the best I have seen this season, well marked and good in colour; it is sure to stand well when sent out, if in condition. The attendance of visitors was very good; in fact, the room was crowded. The following is the prize list:—

MEMBERS' CLASSES.

BELGIAN.—*Clear Yellow*.—1, J. Bexson, Derby. *2*, T. Keys, Derby. *Clear Buff*.—1, T. Keys. *2*, J. Bexson.

NORWICH.—*Yellow*.—1, J. Audley, Derby. *2*, S. Harris, 3, J. G. Edge, 4, J. Orme, 5, J. Judge. *he*, W. Sherwin, C. S. Bunting. *Clear Buff*.—1, J. Orme, *2*, J. Marshall, 3, S. Bunting, 4, D. Audley, 5, G. Fisher. *he*, J. Nichols, C. J. Keys. *Marked Yellow*.—1, T. Keys. *2*, S. Harris. *3*, E. Orme. *4*, G. Fisher. *5*, W. Sherwin. *he*, C. Marsden, C. Upton. *Marked Buff*.—1, J. Orme. *2*, S. Harris. *3*, J. Marshall, 4, J. Nichols, 5, J. Bennett. *he*, J. G.

EDGE. C. C. MARSON. *Variagated Yellow*.—1, A. Utton. 2, S. Bunting. 3, T. Keys. 4, J. Judge. 5, S. Harris. *hc*, J. Marshall. C. G. Fisher. *Variagated Buff*.—1, J. Marshall. 2, A. Knight. 3, J. G. Edge. 4, R. Crossall. 5, J. Bennett. *hc*, S. Stokes. C. S. Harris. *Crested Yellow*.—1, T. Keys. 2, W. Sherwin. 3, J. Stokes. *Crested Buff*.—1, S. Over. 2, N. Banks. 3, W. Sherwin. 4, J. Durance. *Green* (Yellow).—1, G. Fisher. 2, J. G. Edge. 3, J. Judge. (Buff).—1 and Special, G. Fisher. 2, J. Judge. 3, A. Knight.

LIZARD.—*Golden-spangled*.—1, S. Bunting. 2, T. Keys. *Silver-spangled*.—1 and Special, S. Bunting. 2, A. Utton. 3, T. Keys.

CINNAMON.—*Jonque*.—1, J. Bexson. *Buff*.—1, J. Judge. *Marked* (Yellow).—1, J. Judge. 2, J. Bexson. 3, A. Knight. (Buff).—1, G. Taylor. 2 and Special, J. Bexson. 3, W. Sherwin.

GOLDFINCH MULE.—*Jonque*.—1, S. Bunting. 2, J. Judge. *Mealy*.—1, S. Bunting. 2, J. Bryan. 3, J. Judge. *Dark Jonque*.—1, A. Knight. 2, J. Judge. *Dark Mealy*.—1 and Special, S. Bunting. 2, J. Judge. *Any other Variety of Mule*.—1, J. Bryan.

OPEN CLASSES.

NORWICH.—*Clear Yellow*.—1, W. Jerram, Nottingham. 2 and c, S. Bunting. *hc*, T. Keys. *Clear Buff*.—1 and *hc*, J. Bennett, Derby. 2, J. Prosser, Derby. C. S. Bunting. *Marked Yellow*.—1, J. Bennett. 2, J. Prosser. *hc*, W. Jerram.

Variagated Yellow.—1 and c, W. Jerram. 2, T. Keys. *hc*, J. Poole, Sutton-in-Ashfield. *Variagated Buff*.—1, J. Kevel. 2, W. Jerram. *hc*, J. Clarke, Derby.

BELGIAN.—*Clear Yellow*.—1, J. Close, Derby. 2, J. Turner, Derby. *hc*, T. Keys. *Clear Buff*.—1, J. Turner. 2, J. Close. *Marked or Variagated Yellow*.—1, S. Bunting. 2, J. Turner. *Marked or Variagated Buff*.—1, J. Turner. 2, S. Bunting. *hc*, J. Close.

LIZARD.—*Golden-spangled*.—1, J. Poole. 2, W. Bacon, Nottingham. *Silver-spangled*.—1, J. Poole. 2, T. Keys.

GOLDFINCH.—1, S. Bunting. 2, T. Keys.

LINNET.—1, T. Keys. 2, F. Balderstein, Derby.

BANTAMS (Irrespective of breed).—1, H. Shumack. 2, J. Bow. *hc*, D. Otwell; A. D. Forrest, Derby; J. Slater, Meynold, Langley. c, D. Otwell; J. S. Watson, Delper.

JUDGES.—*Canaries*: Mr. G. Moore, Northampton; Mr. E. Bemrose; Mr. G. H. Goodwin. *Bantams*: Mr. G. A. Crewe, Etwell.

DARLINGTON CANARY SHOW.

MESSRS. DENHAM and Stewart's anxieties were quieted on Friday last with a goodly entry of more than 250 birds. Southampton with its tempting schedule stood in the way, while the Derby Show possibly attracted some who would otherwise have sent north; but the energy of the officers of the Darlington Society overcame all difficulties, and local and other exhibitors, responding to the appeal of the Secretary, sent liberal entries for the support of a show which deserves well of the fancy.

"WILTSHIRE RECTOR" is right—the field is not large, and it does become tedious to travel over the same ground frequently. It is only now and then, when some new name appears in the catalogue, or some new star shines out in the firmament, that detailed descriptions of individual specimens will interest. One meets with the same birds show after show, and some evergreen specimens even year after year, which chirp out a cheery "how d'ye do" with all the vigour of youth, having apparently taken a fresh lease of life with their new suit of clothes. The chief points of interest in a show are the new birds, and most of these I think I reviewed in my notes on Scarborough. Appended will be found a list of the prizetakers, and if I select anything as being worthy of special note it must be the Brown Linnet Mules shown by Mr. Spence and Mr. Robinson, and Mr. Rutter's Belgians. The Mules are remarkable birds, Mr. Spence's being a cock of good size and colour, pencilled on the eyes—the marks being somewhat enlarged in the direction of the neck—small cap, wings evenly, lightly, and decidedly marked, slight discoloration of the silky fluff at the rump, with the rest of the body and tail quite clean. Mr. Robinson's is a hen, and is, of course, smaller, and carries but little if any colour, is nicely pencilled on the eye, though one mark extends into something which assumes the character of a blotch on the neck, top of the head clean, wings nicely marked but much piled at the base of the saddle, and a black feather on one side of the tail. Mr. Rutter's Belgians are well known; suffice it to say that the oldest fanciers admitted they had never seen such birds before, and not a few said they did not know such things existed except in pictures. Mr. Rutter held a grand levee on Saturday afternoon, "lifting" his beauties and putting them "up" regardless of the wear and tear of his finger nails, illustrating their "points" with a terseness of style and aptness of simile which only those who have heard him can appreciate. A group of fanciers round a Belgian is a study for an artist.—W. A. BLAKSTON.

BELGIAN.—*Clear Yellow*.—1 and 2, J. Rutter, Bishopwearmouth. 3, F. Rawnsley, Bradford. *Clear Buff*.—1 and 2, J. Rutter. 3, G. Tomlinson, Stockton. *Variagated, Ticked, or Uneven-marked*.—1 and 2, J. Rutter. 3, T. Craggs, Stockton.

NORWICH.—*Clear Jonque*.—1 and 3, T. Irons, Northampton. 2, W. Gamble, Northampton. *Clear Buff*.—1 and 2, W. Gamble. 3, R. Lavfield, Darlington. *Evenly-marked Jonque*.—1, E. Mills, Sunderland. 2, R. Hawman, Middlesbrough. 3, J. Robson, Morthth. *Evenly-marked Buff*.—1, W. & C. Burniston, Middlesbrough. 2, W. L. Heloe, Berwick-on-Tweed. 3, G. Gayton, Northampton. *Dark or Grey-crested*.—1, R. Hawman. 2, T. Irons. 3, J. Calvert, York.

CANARY (Any Crested variety).—1, Fairclough & Howe, Middlesbrough. 2, W. Cotton, Middlesbrough. 3, G. Gayton.

LIZARD.—*Golden-spangled*.—1, R. Ritchie, Darlington. 2, E. Mills. 3, P. Rawnsley. *Silver-spangled*.—1 and 3, R. Ritchie. 2, J. Baines, York.

CINNAMON.—*Jonque*.—1 and 3, T. Irons. 2, S. Tomes. *Buff*.—1, T. Irons. 2 and 3, W. Gamble.

YORKSHIRE.—*Clear Yellow*.—1, H. Winter, Guisborough. 2, E. Mills. 3, L. Belk. *Clear Buff*.—1, W. Hutton, Leeds. 2, E. Mills. 3, J. Cooper, Middlesbrough. *Evenly-marked Yellow*.—1, P. Rawnsley. 2, Stevens & Burton, Middlesbrough. 3, A. Webster, jun., Leeds. *Evenly-marked Buff*.—1, R. Hawman. 2, P. Rawnsley. 2, Tenniswood & Brown, North Acliam.

ANY OTHER VARIETY.—1, R. Hawman. 2, T. Wales, Stockton. 3, W. Bulmer. 3, W. Russell, Darlington.

MULE.—*Evenly-marked Buff Goldfinch*.—1, W. & C. Burniston. 2, J. Robson. 3, R. Hawman. *Dark Goldfinch*.—1, Stevens & Burton. 2, E. Stansfield, 3, H. Winter. *Any other Variety*.—1, J. Spence. 2 and 3, C. Robinson.

CANARY (Clear Green).—1, G. Atkinson, Gateshead. 2, Stevens & Burton. 3, Goldfinch. —1, Stevens & Burton. 2, Tenniswood & Brown.

LIZARD (Brown).—1, Tenniswood & Brown. 2, A. Webster, jun.

BRITISH BIRDS (Any other Variety).—1, A. Fletcher (Starling). 2, W. Hodgson, Darlington (Thrush).

PARROT (Any variety).—1, — Moses, Darlington. 2, J. Scott, York. 3, T. Bowman, Darlington.

FOREIGN BIRDS (Any variety).—1, J. Calvert. 2, W. J. Stewart (Cockateils). 3, W. Hodgson (Love Birds).

JUDGE.—Mr. W. A. Blakston, Sunderland.

CROYDON COLUMBARIAN SOCIETY.

THE amateur Pigeon fanciers of Croydon and its neighbourhood being very numerous, have formed themselves into a Society under the above title, and have arranged to hold their meetings monthly, at the Greyhound Hotel, Croydon. Amongst the members are some of the principal breeders and fanciers in the country, and in a short time the Society will doubtless become one of the most prominent. One of the rules is the total exclusion, either as members or visitors, of all persons who come under the denomination of dealers, and it is the intention of the new Society to limit its members to amateur fanciers only. The officers are to be elected annually, those for the present year being F. S. Wiltshire, Esq., President; T. T. Keen, Esq., Vice-President; and Mr. J. B. Jayne, Honorary Secretary and Treasurer.

THE YORK RABBIT SHOW

THE schedule of prizes for Rabbits, issued by the Poultry Committee of the Yorkshire Society for the exhibition of fat stock, is the very best ever issued by any committee in England. Take the schedule of the last show of the Hull Society, now extinct, of which your correspondent, Mr. S. G. Hudson, was one of the committee, and we find three classes for Lop-ears, and a silver cup; only two classes for fancy varieties, and no cup nor anything. Also, take the Rochdale, Keighley, Long Sutton, Middleton, and Airedale Shows, and we see that there is not nearly so much money offered, nor so many classes, as at the York Show.

As to those two £5 5s. cups for Lop-ears, they have been collected by those who are fanciers of Lop-ears only. If your correspondents had wished to have had a cup for the fancy varieties, they should have expressed their desire, the same as the Lop-ear fanciers did, written to the Committee guaranteeing the cup, and have collected the money for it. The Committee would have been only too glad for them to have done so. The medal for the fancy varieties has been given in this way; a gentleman thought we ought to have something, and gave practical expression by collecting for a medal.

As to the fancy varieties being shown in pairs, I differ from your correspondent; I think they ought to be shown in pairs, and from what he states it seems he has never attended the York Show, or he would have seen, instead of disgusting scenes, and Rabbits going home in a breeding state, that the pens are divided, the Rabbits having no chance of being together.

Since giving up the fancy it has been my desire, as far as possible, each year to improve the schedule, and in this I have succeeded; a year or two since there were only some £4 or £5 given in prizes, now there are £12 10s., besides the cups and medal, and since last year we have added some £1 to the schedule, the major part of which goes to the fancy varieties, and if we are encouraged this year with large entries in those classes, we intend to ask the General Committee for more money, and make all classes equal; but we cannot do this unless we have the support of the exhibitors; and let those gentlemen remember that there is only a difference of 5s. in the first prize, the second being equal with the Lop-ears. It is impossible for a society to give valuable prizes unless they have large entries, and we do think we ought to be largely patronised for the prize list issued. I hope all Rabbit exhibitors in England will enter largely. Our Show is perfect in its arrangements; we have a man to each department night and day, the Rabbits are fed with suitable food three times a-day, and are returned with the utmost despatch; and I can promise all exhibitors that they may send their stock with safety, for their specimens will be as comfortable as at home.—M. MILLINGTON, York.

GREAT LONDON POULTRY SHOW.—We would draw the attention of intending exhibitors to the schedule of the above Show, the prizes being very valuable and the classes excellently ar-

ranged. Exhibitors of nearly every variety of poultry and Pigeons will here find a class. It will be noticed that the entries close on Saturday next, November 12th.

CHAUCER'S CHANTICLEER.

In the "Canterbury Tales" Chaucer describes a "Cok highte Chanticleere" as follows:—

"His combe was redder than the fin corral,
Embattled, as it were a castel wall,
His bill was black, and as the jet it shone;
Like asure were his legges and his tone;
His nyles whiter than the fly flour,
And like the burned gold was his colour."

The only word in the foregoing passage requiring the aid of a glossary is "tone," which means toes.

We have described, then, as *the* cock of the fourteenth century a single-combed bird (for I judge the phrase "embattled, as it were a castel wall" refers to the serrations of the comb which justify the comparison), probably of a reddish colour, with a black bill, with blue legs and toes, and with white nails. Chanticleere probably had neither crest, muff, nor beard; his deaf-ears were not conspicuous, and his wattles were not large, otherwise we may be sure the poet would have mentioned them. What was his breed? Must we yield to the dung-bill the honour of a place in "Canterbury Tales" or can we claim it for some of our favourites of to-day?

The description suggests the Golden Hamburg, but the description of the comb will hardly do; so observant a man, who is so minute and careful, would not have omitted the conspicuous white deaf-ear. Nor can we claim it for our Golden Polands for similar reasons.

The only other point of interest connected with chanticleere worth mentioning is, that "this cok had in his governance seven hennes."—(*Poultry Bulletin*)

HOW LONG ARE YOUNG QUEENS IN EMBRYO?

I wish it to be understood that in all my experiments I have left nothing to chance. My hives are not dark straw hives, where the natural history of the bee is at the best but a surmise, but are frame hives (condemned in "The Handy Book"), capable of being transformed into observatory hives in a few minutes, and from these my observations have all been taken.

Now, the first question I have before me is, Do bees carry eggs from one hive, or from one part of a hive to another, and place them in royal cells? I say unhesitatingly, No; for I have witnessed hundreds of queens raised and hatched, and have placed these eggs in the most unfavourable positions, so that if bees ever did shift them, they would certainly have done so; and, as a proof of this, I have at present a piece of comb with seven queen cells, which was commenced inside a hive, but which was removed outside, and although eggs were present, the bees failed to carry in a single one, but have continued to stick to the comb with royal cells outside the hive, the eggs in which are at this moment within a few hours of hatching.

The next question is the one now in course of discussion regarding the time queens are in being hatched. To this I would reply that it depends on circumstances, and the circumstances are these. Suppose we take a piece of comb with eggs and brood in all stages, and give it to a hive without a queen, in all probability the bees will commence to raise queens from both eggs and grubs, and in thirty hours we may find one or more queens sealed over, and which will be hatched on the ninth day, or exactly eight days from the time of being sealed. Others in a less forward state will be later, and some may extend to the seventeenth day, exactly sixteen days from the depositing of the egg, which is what we want to know—viz., the exact time from the old queen leaving the cell, where she has deposited the egg, until the time the young queen makes her exit from the same cell. In all cases where I have either seen the eggs deposited or knew when they were laid, I have never known a queen hatched in less time than sixteen days, or on the seventeenth day after the egg being laid; and instead of their being less than sixteen days, I have known them kept prisoners for twenty, and even twenty-one days after being laid. This imprisonment occurs only in hives intending to swarm therefore ocular demonstration proves that it requires sixteen days to bring a queen to maturity. I can with safety say that I have been present at the birth of the majority of my queens hatched during the past six years, and I may add, so near was

I in my reckoning, allowing sixteen days, that I have often caught them in the act of leaving their cells, and have seldom had to wait many hours until they did so.

There is another question—viz., Can queens be raised from drone eggs, or rather eggs that would produce drones? My answer to this is, No; and any person who says that they can has but a very imperfect idea of the natural history and anatomy of the honey bee. Without entering into details on this subject, I will merely quote one instance as a proof against this theory, and ask why bees fail to produce queens from the eggs of a virgin or drone-breeding queen?—A LANARKSHIRE BEE-KEEPER.

A DIFFERENCE of opinion appears to prevail in regard to the length of time required for the evolution of a queen from an egg. Mr. Woodbury has fixed the period at sixteen days, or thereabouts, and to my mind no evidence has yet been adduced to show that he is mistaken. The fact can only be determined by correct observation and experiment.

With a view to solve the problem, or rather to obtain additional proof on the point, I introduced on the 25th of August last a fertile queen to a populous hive containing plenty of honey, but neither eggs nor brood. On the 29th and 30th eggs were deposited in one of the combs over a space of 4 square inches, and then I removed the queen that others might be raised from the eggs. Royal cells were only formed, but on the afternoon of September 13th none of them were found opened, although fully fourteen days had elapsed from the hour of the old queen's removal. It was not till the morning of September 14th that the eldest young queen obtained her liberty. Moreover, this queen emanated from one of the earlier-laid eggs; all the more recently-deposited ones having been removed, and perhaps eaten, by what are called nurse bees. On several occasions when making artificial swarms I have observed that all newly-laid eggs were destroyed. I am not prepared to say that this curious circumstance may be witnessed in every instance where bees are made to evolve young queens from a comb containing eggs, but it certainly does very frequently happen. Sometimes when a comb has contained eggs only, all but those destined for queens have been destroyed, not a single bee having been allowed to be hatched from one of the eggs. In cases where there are larvæ as well as eggs, it will be found that the recently-deposited eggs are also made away with, although all the larvæ are carefully nursed.

The facts now stated have not, so far as I am aware, been mentioned by any writer, and I would not at the present moment have alluded to them but for their bearing on points now debated; for if a comb contained eggs only, and the age of the eggs in each portion of the comb has not been well ascertained and marked, it is quite impossible to fix what length of time has been occupied in the evolution of a queen from any of them.

The experiment I have detailed shows that it required, under very favourable circumstances, and during remarkably fine weather, more than fourteen days for the production of royalty from an egg, and I suppose most apiarists entertain the belief that an artificially-reared queen is not detained in her cell a single moment beyond her wishes. If it is the case that young queens occasionally make their appearance before the sixteenth day, dating from the moment when the egg was placed in the cell, they will, I imagine, present an immature appearance. I must, therefore, in the meantime hold to the conviction that either observations not made with sufficient accuracy, or that exceptional cases of premature birth, have led to the erroneous belief that fourteen, and not sixteen, days are required in the production of queens.—R. S.

OUR LETTER BOX.

PARTRIDGE COCHIN-CHINA AND BLACK RED GAME COCKS (*Torquay*).—Neither red dull in the first, nor blue legs in the second are disqualifications, nor are they even faults of any importance. We repeat that which we had said many times—there is no colour for the legs of a Game fowl which is a test of purity or otherwise. The only rule with regard to them is, that there must be positive uniformity of colour in the legs of all the birds that go to form a pen.

BRAHMA'S EYE SWOLLEN (*W. S.*).—In any other breed than the Brahma or Cochin the inflation of the skin of the face or lower beak would be a very serious symptom. If neglected it would end in rot. It is, however, of little import with Brahmas. The bird has probably caught cold, and will soon be well. Wash the face morning and evening with cold water and vinegar; give a little stimulant twice per day, such as bread and strong beer, and until convalescence give two pills daily of camphor, each the size of a garden pea.

LAYING SOFT EGGS (*Idem*).—This arises from one of two things—either

the necessary material is not to be found in the haunts of the hen, and in that case it must be supplied in the shape of bricklayers' rubbish, old ceilings, chalk, lime, &c., or the secretions are at fault. Try the first. If it does not succeed, attribute the result to the second cause, and use Bailey's pills, which will, we doubt not, effect a cure.

COCHIN PELLETS DYING (F.).—There is nothing in your keeping that should cause your fowls to die. Your dietary is not of a high class, and if the birds came from much better keeping they would lose condition. A large gravelled atleyard otherwise unoccupied is not suggestive of healthy feedings; and Indian corn twice per day, varied sometimes with barley meal and tainag wheat, is not good feeding. With a little alteration it may be good enough. A sickly person may be ordered to take turtle, but if entirely confined to it would starve. Just so the Indian corn thrown down in the clean gravelled yard is suggestive of the children's cry, "Sick of the sight of it," when their parents expatiate on the merits of some dish on which they pin their faith. We fancy your fowls are like Dr. Blimber's boys as they appeared when enjoying themselves, whereas they should be like those unhappy children who had no one to take care of them, and who were in consequence "doing dags," "turning wheels," and "standing on their heads." Have two or three or more cartloads of road grit full of grass and small pebbles. Form them in a heap in the yard. Make another with as much mould as you can spare, cover the top of it with large sods of growing grass. Feed on barley meal or ground oats as the principal food, and let Indian corn be the occasional change. As some of the youngest chickens may want it, give them bread and milk and a little chopped egg till they have recovered strength. Cleanliness cannot be too much insisted upon in the roosting place or house; but where the runs are so intolerably clean and tidy, we are compelled to believe either that the fowls have not the various appliances necessary to health, or they are not in health to make use of them.

DISEASED CROSS-BRED HEN (E. S.).—The complaint you mention belongs more to the Spanish than the Cochlin broed. It is seldom cured, but the fowls live on, and are as useful as if they had not the excrescence. In the early stages, when the swelling is soft, it can sometimes be got rid of by making an opening and squeezing out the contents, which will generally be found to be a cheesy substance. Bailey's pills, we believe, are to be had of all the principal chemists, or at 113, Mount Street, W., London. They are very useful in keeping fowls in health at this time of year.

COCK'S TOE PARTLY LOST—HAMBERG COCK'S COMB (Constant Reader).—The accident to the Cochlin cock is of no importance. The double pike to the Hamburg's comb will be fatal if it is discovered.

BRAHMA PULLETS AND COCK (Orl.).—They should be set apart at once. They will probably lay the end of next month. Give them the largest space you can. If it possesses green food in the way of grass, &c., you need not provide it. If it does not, you must supply the same with road grit, garden mould, growing grass, and other green food. If they have a good run and the consequent advantages, give two meals per day of whole corn, the middly one of barley meal or ground oats. As they are growing birds you may also give them kitchen scraps and bread and milk. In very bad weather you may give them bread and ale morning and evening, we mean during snow or long-continued wet. Be sure their roosting place has none other than an earthen floor, and that the perches are very wide and not more than 18 inches from the floor.

SILVER-PENCILED HAMBURGERS (M. I. M.).—Assuming that all your cockerels are of the same age, we should certainly give the preference to the perfect earlobe. If they are all of the same strain, and he of the white ear be older than the others, we should not hurry to make our selection, because age will often transform the faulty into a perfect earlobe, just as it does the face of a Spanish pullet.

POULTRY FOR SALE (Notice).—Fit for exhibition is a wide term, and binds the seller to nothing. You need not wait long. Go to Birmingham Monday fortnight, and you can buy birds that have actually appeared in the first prize sheet in the world. We do not think you would be likely to buy prize birds from anyone who never takes prizes, as, even in his own case, his estimate of the merits of his birds is a mistaken one. If there were only open classes for "birds of all ages," the age of the birds forming competing pens would be taken into consideration, but one six months old would hardly ever compete successfully with one twice the age. Still at almost every show there are distinct classes for chickens and adults. The probable success of six-months chickens would depend on the time of year at which the show was held. Thus, at a show held in July it would be very difficult to get chickens more than six months old, and they would, if good, be successful. The same chickens, or their fellows, might be shown in November or December, being then nearly a year old and as such adults as they ever would be, chickens six months old would have no hope in competing with them, although they might have done so in July. Early maturity is one of the objects aimed at by those who encourage the breed of poultry. To produce chickens late in the year is of little use, as they are then of small value.

MALAYS (Minorca).—They are not Game fowls, and, if there is not a separate class for them, they must be exhibited in the "Any other variety" class.

CHICKENS CROP-BOUND (C. T.).—Your feeding must be wrong, and your fowls consequently become crop-bound and die. Those which have their crops full must have them emptied. Feed on green meat and ground food. See our instructions to "F. T." last week; we entered fully into the subject.

BRAHMA WITH TWISTED FLIGHT (T. F. A.).—Your hird has a twisted flight, and nothing will cure it. It is always a mistake to save such chickens, as they are worthless for stock, and to our ideas blots in a yard. We always devote them to the kitchen. "Wise men flustering" may tell you of cures. We have never found one.

COLOUR OF DARK BRAHMA HEN (Item).—The brown or salmon colour is a defect in a Brahma hen. If we had others as good, lacking the colour, we should not breed from her. If she has qualities that make it desirable, we should mate her with a Dark cock—that is, black and white, and above all, one without the chestnut patch on his wing or a brown feather in any part of his plumage.

EXHIBITION DARK BRAHMAS (Brahma).—We advise you to show No. 2 for two reasons. You say she is nearly as large, is better pencilled, and has no brown in her plumage. No. 1 is evidently out of health. There is no greater proof than inordinate thirst. Remove the water at once;

let her have a little morning, midday, and evening, but none to stand by her. Feed her moderately on soft food. Give her lettuce. If the thirst continue, give castor oil.

RARDS' EYKS (Belton).—As the pearl eye in these Pigeons is the proper colour—vide the article on the Pigeon in our number for October 27th—on no account cross with a bird having a crocus eye, as you will damage your stock, and get the yellow eye into it.

MEASURING THE FACES OF CARRIERS AND BARDS (Jas. Urgan).—We think the safest and best way to measure the faces of watted Pigeons is from their point to the centre of the eye itself, certainly not to the outside of the eyeball.

CURING RABBIT SKINS (Orl.).—We know nothing about the process.

COOKING SCORZONERA (N. H. P.).—You guessed erroneously; our cook's name is not "Betty," but Alicia, indicative of being quite up to palatable preparations; yet, when we imparted to her your question, she inquired, "Is it a 5-h?" so we retired from taking further counsel, and impart the following from the store of our own encyclopaedic knowledge:—Scrape off the dark outside skin of the roots; then soak them in water for an hour or more to extract a portion of the bitterness; then boil them till soft, like the parsnip, and send to table to be eaten with either white sauce or melted butter.

METEOROLOGICAL OBSERVATIONS In the Suburbs of London for the week ending November 8th.

Table with columns: DATE, BAROMETER (Max, Min), THERMOMETER (Air, Earth: 1 ft, 2 ft), Wind, Rain. Rows include Wed, Thurs, Fri, Sat, Sun, Mon, Tues, and Mean.

- 2.—Foggy; fine, foggy; frosty fog at night.
3.—Frosty fog; foggy, dense fog; frost, dense fog.
4.—Dense fog; densely overcast; overcast.
5.—Densely overcast; very fine; densely overcast.
6.—Densely overcast; fine; densely overcast.
7.—Frosty; rain; fine; heavy clouds.
8.—Frosty air; dense fog; foggy and frosty.

COVENT GARDEN MARKET.—NOVEMBER 9.

THE attendance of buyers has been hot limited during the past week and as the stocks have much accumulated forced sales have been resorted to, but without much influencing the current rates. Some heavy consignments of Pears from France, shipped at Dieppe and St. Malo, have passed under the hammer this week. We have also received a good parcel of Newtown Pippins from New York. The Potato trade is rather active.

FRUIT.

Table of fruit prices including Apples, Apricots, Cherries, Chestnuts, Currants, Figs, Filberts, Gooseberries, Grapes, Lemons, Melons, Mulberries, Nectarines, Oranges, Peaches, Pears, Pine Apples, Plums, Quinces, Raspberries, Strawberries, and Walnuts.

VEGETABLES.

Table of vegetable prices including Artichokes, Asparagus, Beans, Broad, Beet, Broccoli, Brussels Sprouts, Cabbage, Capsicums, Carrots, Cauliflower, Celery, Coleworts, Cucumbers, Fennel, Garlic, Herbs, Horseradish, Leeks, Lettuce, Mushrooms, Mustard & Cress, Onions, Parsnips, Peas, Potatoes, Quinces, Radishes, Rhubarb, Savoy, Sea-Kale, Shallots, Spinach, Tomatoes, Turnips, and Vegetable Marrows.

POULTRY MARKET.—NOVEMBER 9.

THE supply is moderate, and the demand very small. The lamentable war on the Continent has closed our best markets for the sale of Game, and will influence the price of it greatly. We expect it will be difficult to sell many pheasants, except at very low rates.

Table of poultry prices including Large Fowls, Smaller ditto, Chickens, Ducks, Geese, Pheasants, Pigeons, Rabbits, Wild ditto, Hares, Partridges, and Grouse.

WEEKLY CALENDAR.

Day of Month.	Day of Week.	NOVEMBER 17—23, 1870.	Average Temperature near London.			Rain in last 43 years.		Sun Rises.		Sun Sets.		Moon Rises.		Moon Sets.		Moon's Age.		Clock after Sun.	Day of Year.

23	W	ST. CLEMENT.	47.6	34.2	40.9	18	33	7	2	4	45	7	39	4	30	13	25	327		

From observations taken near London during the last forty-three years, the average day temperature of the week is 48.6°, and its night temperature 34.3°. The greatest heat was 61°, on the 20th, 1866; and the lowest cold 18°, on the 19th, 1868. The greatest fall of rain was 0.35 inch.

FRUIT TREES FOR SMALL GARDENS.—No. 1.

ROBABLY no gardens are so much neglected and on the whole so badly arranged as farm and cottage gardens. Horticultural societies established in almost every town encourage improvements of various kinds; and there is the horticultural press placing within the reach of all information on gardening that will not fail, if acted on, to improve both flowers and fruit. Nothing, however, seems as yet to have made any salutary impression

on the minds of the great mass of British farmers and cottagers, many of the latter being employed by the farmers, who ought to give them encouragement, and set an example of good management in their own gardens. Horticultural societies and the gardening journals to a laudable extent encourage cottagers to attend to the culture of their gardens, but how can they hope to succeed when employers offer such examples of slovenly garden management? It is remarkable that gentlemen, especially landed proprietors, who for the most part have tasteful, productive, well-kept gardens, do not take notice of the neglected and slovenly condition of the gardens attached to their farmhouses, and do not use their influence with their tenants to induce them to pay more attention to garden-culture and keeping.

Although agriculture and horticulture are kindred pursuits, strange to say there is no class of the community so ignorant and destitute of taste in respect to gardening as the great majority of our farmers. To such a pitch is this disregard for the garden carried that many of them own their ignorance with a clownish boast, as if the culture of their gardens were a concern utterly contemptible, or far below their notice. Some members of their family may have a taste for the culture of flowers, fruit, or vegetables; but the ill-assorted, discouraged, and often abortive attempts at anything like taste or ornament are more calculated to excite commiseration than any other feeling. There are, no doubt, some well-arranged, well-managed farmhouse and cottage gardens, but such are not the general rule.

Can nothing be done to remedy this contempt of farmers and cottagers for their gardens? Horticultural societies have offered premiums time after time; the press has chronicled the event, and instructions have been given so often that one might if so disposed have had them off by heart; but after all the gardens remain as they were before. It is not want of taste for flowers and fruit that withholds farmers and cottagers from attending to the culture of their gardens, for they are ardent admirers of both. They take pleasure when spring returns in wandering in gardens, and seeing the Lilies shooting from the ground, and the buds of the fruit trees full even to bursting. They wonder how a Crab grew into an Apple, the Sloe into a Plum, and the single became a double Daisy. It is a marvel to them how the Vine bears its Grapes, and the Pine Apple has its summer flavour whilst the snow is as yet unmelting on the hills. None admire more than they do the beauties of choice flowers and fruits, but after

they have highly extolled all they see in our best gardens they find something that affords them a sort of consolation—they have seen many fine fruits, but none equal to what they have, perhaps by the bushel, from a standard tree.

Another obstacle to farmers and cottagers moving from the old track is they see no place for fruit trees but an orchard, and no description of trees but standards. As to kinds, they do not look for better than those which they or some neighbour may have—sorts that are very often but slight removes from our Crabs. If prevailed on to procure new kinds, they think these must be grown as standards, and the expectation of getting as fine fruit from them as they see elsewhere on bushes, pyramids, or espaliers turns out a miserable disappointment, for the kinds are wholly unsuitable for standards, like almost all our best varieties of Apples, Plums, and Pears.

Another cause of the adherence of farmers in garden matters to old notions consists in the persons applied to for information when anything new is contemplated. In almost every village there is the presiding genius in the man who has a neat garden of his own, and grows plants for sale, besides going out to "do-up" gardens. Brought up in orchards, and believing in no garden unless it is shaded by standard trees that will neither allow of flowers succeeding nor of vegetables attaining perfection, his ideas do not soar higher than his knowledge. He advises, and his advice is generally adopted, for it is in accordance with their own opinions—adverse to what are called new-fangled notions. This person advises and plants for the British farmer, and his cottager procures through him fruit trees of inferior kinds, and of a description more likely to fruit with the next tenant than with the present one. What a wondrous creature of hope—hope that a tree with a stem like a walking stick and a head like a mop will grow and become strong and spreading like an Oak, as it must before it will produce the bushels of fruit expected of it! Until garden knowledge be more generally diffused—until there be in every village competent persons able to act and advise on gardening in its best and most approved principles, there will be that paradise of prejudice in which men dream away their time.

It has been said, and I think wisely, that those prepared to point out a grievance should be prepared with a remedy. The first suggestion that I have to offer is that the clergy of every parish should undertake the instruction of cottage gardeners. Being in general well posted up in the best and most improved kinds of fruits, the most profitable form of trees or systems of growing them, and, from their avocation looked up to, their advice and instruction would go a long way in producing a change. Indeed, with a well-kept garden, at times free to the inspection of the villagers, especially if it could be backed up by a show, there would be awakened such a spirit of innocent rivalry and a desire to excel in garden produce that any extra trouble would not be felt, whilst the improvement would be manifest everywhere, giving to many a family a health more precious than rubies. Some, I am aware, are already engaged in this noble work—aiding in fulfilling the intentions of

Providence, striving to give to every home health, comfort, and happiness. Could not they be prevailed on to give in the "Cottage Gardener" columns the benefit of their experience for the good of others, who are only kept from the work from want of a plan?

With the farmers it would perhaps be more difficult to deal. Persuasion and example would avail but little, but could they not be reached through the landlord? What if the landlord were to provide a properly qualified gardener, competent to renovate the gardens attached to farms or houses? This person might be found by the landlord, the farmer paying him for his labour at a rate fixed by the landlord, or the expense might be wholly paid by the landlord in the first instance, the tenant being charged with the interest of the outlay in respect of stock and improvements, the "keeping in order" being paid by the tenant. I am sure that farmers, as a rule, would not object to this sort of thing, but would do all in their power to further it. The only difficulty would be in making sure of the person appointed having the requisite knowledge. I am not unmindful of "A YOUNG GARDENER'S GROWL," but I do not think so few gardeners as he states are able to advise as to a list of fruits, and that without tasting, as he will learn by-and-by when he has to supply fruit for the kitchen and dessert. But any objection of that kind might be got over by the landlord's gardener having the supervision of the gardens and the control of the persons who attend to them. In that case nothing could be done to the detriment of either the landlord or tenant, as might otherwise be the case were an inexperienced hand to cut down what could not be replaced without entailing a serious loss on the tenant, and he could be kept from planting what would not be of any value to him, or not for a very long time. The landlord might stipulate for a certain amount of flower, vegetable, and fruit garden, and an orchard if thought necessary, to each holding, and the occupiers could exercise their discretion in what they would have it cropped with, always keeping from them the power of interfering with the permanent subjects without first consulting with the landlord or his agent.

The gardener should be able to lay-out gardens, and practically understand every department of out-door gardening. On some estates it would be necessary to have a superintendent, with properly-qualified assistants. It has always appeared to me remarkable that the gardening market should be overstocked, and yet there is no wonder when half the gardening of the country is performed by persons styling themselves gardeners, but knowing practically but little of it outside their own minds.—G. ARBEY.

CLIMBING FERNS.—No. 3.

In my two previous articles I have confined myself to Ferns whose fronds have the power of extending themselves, if not indefinitely, at least to a very unusual length, by the continuous growth of their points. We now, however, come to a distinct set of plants, which, although they must undoubtedly be accepted as climbing Ferns, yet owe their claim to this title only from the extension of the rhizome which roots into or around whatever it can affix itself to. Very fine objects can be made with some of these by planting the dead stems of tree Ferns in various parts of the fernery, and fastening upon them the kinds with scandent rhizomes; or if no tree Fern stems are to be had, small cylinders of galvanised wire may be placed so as to represent pillars or archways, and these, having been previously filled with peat and sphagnum moss, will be fitting receptacles for the kinds with creeping rhizomes presently to be named. Fern-growers who have not a fernery in which their pots can be planted in the open border need not despair, and, certainly, must not neglect such plants as those treated of in this article, because they will be even more appreciated in a collection that is confined to pot culture; to such I say, Pot your dead Fern stem or your cylinder of wire, then fix the creeping rhizomes to it, when, if duly supplied with moisture, they will soon establish themselves, and the effect will be as good as if they had been planted in the fernery borders.

OLEANDRA.

This is a very elegant and thoroughly distinct genus of stove Ferns, characterised by their hairy rhizomes and simple fronds, which are of firm texture with jointed stipes. The veins are simple, sometimes forked, having a short venule terminating near the midrib, on which the sori are situated, and which are furnished with a reniform indusium. These plants adhere very closely to any congenial surface, and, as a natural

consequence, the more nutriment they obtain, the larger fronds they develop. Several more species than those here enumerated are known to exist, and when introduced in a living state to this country will be valuable additions to our collections.

O. ARTICULATA.—This is a beautiful Fern with entire linear-lanceolate fronds from 10 to 15 inches long, tapering at either end, and light shining green in colour. When treated in the manner previously described, it produces a fine effect. It is a native of the East Indies and the Mauritius.

O. NODOSA.—Like the preceding, this species produces simple fronds, which are about the same shape and size as in that

plant; it is distinguished from it, however, by its black shining stipes, and the darker green of its fronds, part of one of which is represented in the accompanying engraving. *O. nodosa* should be grown in the same manner as before mentioned, and if planted upon the stem of a tree Fern the effect is charming. It is a native of the West Indies.

O. WALLICHI.—This is a somewhat rare kind, but fully as beautiful as those previously named. The fronds are simple, varying from 12 to 18 inches in length, and from 1 inch to 1½ inch in width, with

slightly undulating margins. The sori are large, light brown, and situated very close to the costa or midrib. The colour is bright light green. Native of the East Indies.

O. NEMIFORMIS can only be called a sub-scandent species, but it is such a beautiful plant that I cannot refrain from including it with the others. It has simple fronds about 12 inches in length, arranged in a verticillate manner, which give them the appearance of large fans, and the effect it produces is so strikingly distinct that it should be one of the first plants procured for a collection of Ferns. Native of both India and South America.

POLYBOTRYA.

This genus belongs to the tribe Acrostichæ, although differing considerably in appearance from the plants we are apt to associate in our minds with Acrostichum. They may be known by their stout squamose rhizomes, bi-tripinnate fronds, free pinnate veins, and contracted fertile fronds, which are entirely covered on the under side with sporangia. Polybotryas are large-growing plants, and climb trees to considerable heights. In a large fernery where space for their development can be afforded, they form truly noble ornaments, and should be treated in the same manner as recommended for *Oleandra*.

P. OSMUNDACEA.—In this plant we have boldness of character well developed. It produces a stout creeping rhizome clothed with long brown chaffy scales, and which climbs to considerable heights. Its fertile and sterile fronds are very dissimilar, the latter are bi-tripinnate, from 2 to 3 feet long, with oblong pinnae tapering towards the apex, obtusely lobed, and of a rich green. The fertile fronds are equal in size to those which are sterile, but have all the pinnules contracted into linear segments, which are wholly covered with dark brown sori. It requires stove heat, and forms a fine specimen. It seems to be abundant in Brazil, various parts of South America, and in the West Indies.

P. CAUDATA.—Another superb strong-growing Fern with a stout climbing acaly rhizome. The fronds are tripinnate, lengthened out into a long tail-like point, as are also the pinnae; the pinnules are broad-oblong, rounded at the base, tapering to a point, dentate at the edges, and bright shining green in colour, like *P. osmundacea*; the fertile fronds are contracted, the pinnules being linear, about 2 inches in length, slightly eared at the base on the superior margin, and wholly spangiferous. It is a noble ornament in a large fernery. Native of South America and the West Indies.

ARTHROPTERIS.

This genus would appear to have no striking character or characters to distinguish it, and it seems to me to be very near to *Nephrolepis*, but is wanting in respect to the thin wiry

rhizome so peculiar to that family. Arthropteris has a thin scendant rhizome, and the stipes are jointed, and the pinnae are likewise jointed to the rachis; the latter have free forked veins, the round sori being situated on the apex of the lower venule. Indusium small, and soon obliterated.

A. OBLITERATA is a peculiar plant, and one which has led to much discussion; it has been shifted from one genus to another until one scarcely knows what to call it. This plant may, perhaps, be more familiar to my readers by the name of *Lindsea Lowii*, for by this name it has been distributed, but it certainly bears no relationship to that family. It is also to be found in some collections as *Polybotrya Lowii*, but I am equally doubtful of its proving an acrostichoid Fern at all; it certainly bears more resemblance to Arthropteris than anything else I have seen. In a cultivated state the fronds of this plant have assumed three distinct forms, but as far as I am aware it has not yet fruited, which is much to be regretted. In the first form the pinnae are developed only on one side of the rachis, they are obtusely lobed and decurrent; they are ultimately produced on both sides of the rachis, still lobed, and decurrent; after producing a quantity of fronds of this form suddenly the fronds appear with distant, broad, and entire pinnae, somewhat rounded at the base, and acuminate at the apex. In this state the plant looks very like a *Nephrolepis*, and I do not anticipate any further alteration in its form, saving the production of sori. Its fronds are bright dark green, and it should make a fine object upon the stem of a tree Fern, or upon an artificial pillar. I say it should, because I have never been able to make much progress in its cultivation; the reason I am at a loss to discover, but I shall still endeavour to conquer the difficulty. It has been introduced to our gardens from Borneo, but probably may be found throughout the whole of the Indian Archipelago.

A. TENELLA.—This plant makes a nice covering for the stem of a tree Fern, its creeping rhizome soon mounting to a considerable height, and fixing itself very firmly. The fronds are pinnate, pinnae entire, oblong acuminate, and dark green. It also rejoices in the name of *Polypodium tenellum*, P. filipes, and Arthropteris filipes. It succeeds admirably in a cool fernery. Native of New Zealand.—EXPERTO CREDE.

GROUND LEVELLING AND PRACTICAL GARDEN PLOTTING.—No. 5. DRAWING PLANS.

Fig. 18 is described from an equilateral triangle ABC. From angle c draw arcs d e; divide the space between the two arcs at points f and g with the radius j h and g i, and draw the end arcs, uniting with arcs d and e.

Fig. 18.

Fig. 19.

Fig. 19.—Draw line c n any length. Bisect it in A, and erect the perpendicular line A B from A with radius A D, which is half c D. Draw the arc as shown in c. From any part of the

Fig. 20.

Fig. 21.

perpendicular line A B take a centre, as point f; with radius f b draw the arc as shown in g.

Fig. 20 is drawn from the line A B: Draw line A B any length; divide it into four equal parts, as 1, 2, 3, and 4. With the radius 2, 4, which is half the length of the line, draw arc c; from point 1 draw arc e, as shown by the radius; also from point 3 draw arc d.

Fig. 20.

Fig. 21 is drawn from line A B in the same way as the above figure. Divide the line into four equal parts, as in the preceding case. With the radius 1, 3, draw arc c. From point 2, draw arc f. From point 4 draw arc d.

Fig. 22 is drawn from an equilateral triangle. Draw triangle A B C. Divide each line into four equal parts, as line A B, as shown by 1, 2, 3, 4. With radius 1, 2, which is one-fourth of the line, draw arc d; with radius 3, 2, draw arc e; and so on with the other sides, and the figure will be complete.

Fig. 23

Fig. 23 is drawn by dividing the sides of the equilateral triangle A B C into two equal parts, as shown by 1 and 2. On line A B, from point 1, which is half the line, draw arc d; from point A draw arc e; from point B draw arc f; and so on with the other two sides.

When the arcs are all drawn, draw the straight lines between the arcs.—M. O'DONNELL, Gardener to E. Leeming, Esq., Spring Grove, Richmond.

NOTES MADE DURING A TOUR IN IRELAND: No. 2.

In the immediate neighbourhood of Dublin there are many fine gardens at the seats of the nobility, government officials, and the wealthy tradesmen. Such gardens are very secluded, so that the passer-by can see little of them; still, though I believe the Irish people may be very fond of flowers, yet about Dublin the visitor is struck very forcibly with the lack of these in the prettily-kept gardens of the smaller villas and the dwellings of the poorer classes about Dublin, in comparison with those round London and other English towns. I wish to see displayed a little more of this popular love and regard for flowers; it would not only enhance the beauties of an already beautiful city, but would give much pleasure to the people generally. The people of Dublin have, however, next to our own royal gardens of Kew, the best botanical garden—viz.,

GLASNEVIN.

My first object after my arrival in Dublin was to visit this famed garden, where I was very courteously received by its talented director Dr. Moore. The botanic garden of Glasnevin is naturally very beautiful; it lies a little to the north of Dublin on the main road leading from Sackville Street through rather a poor low neighbourhood, giving one a rather unfavourable impression of what is to be seen. Once at the gates, however, all this vanishes, and we enter, I should say, one of the prettiest and most interesting public gardens in the world, especially if the visitor has the good fortune to meet Dr. Moore, who is all kindness, and full of much interesting information respecting every plant in the gardens. Here attention is called to a big tree, there to a little Moss, yet the same interest is attached to both. We are told how, when, and by whom each was introduced, and all the ups and downs of their chequered lives. To true lovers of plants there is nothing more delightful than this kind of talk, so with Dr. Moore I was at once at home. The garden, which is tolerably extensive, is very diversified in character, the surface undulating, having many distinct features, and appearing, perhaps, of greater extent than it actually is. No better style of ground could be selected than this for a public garden, yet apart from its natural beauties it is extremely well designed and tastefully laid out, presenting plenty of green trees and green grass, and pretty winding walks. The beauty

and fashion of Dublin flock here on the Sunday afternoon in great numbers; it is their great meeting place, and a very delightful one. From here also we have a good view of the monument to O'Connell, which is chiefly remarkable for its extreme ugliness, yet it is much thought of. A little is done here in the modern style of flower gardening, there being groups and beds of scarlet Pelargoniums, &c., arranged with good taste and effect, yet in no way destroying the principles of the place as a botanic garden. Botanic gardens, pure and simple, are very dry and uninviting places to the unscientific portion of the people, and there is nothing, I think, more ugly and disappointing than the arrangement of plants in strict botanical fashion. At Glasnevin all are harmoniously and pleasantly blended; it is a true botanic garden, yet every part of it is pleasing and interesting.

The collection of plants both under glass and in the open air is very extensive and varied. There is a considerable number of glass houses, which are very good substantial buildings, well adapted for the purposes for which they are designed, not excepting the large Palm stove itself, although it is, perhaps, one of the ugliest glass structures erected in any country, it having, when viewed externally, more the appearance of a huge overgrown barn than anything else. It is, nevertheless, internally well adapted for its occupants. The height of this hideous pile is upwards of 60 feet; it has a very steep span roof, and one end is of brick, with a chimney as in the gable end of a great farm house. Say what one may about its fine contents and its suitability for them, it is a sad, a great disfigurement to an otherwise almost perfect garden. I believe it cost for erection about £2000, for which sum, although miserably inadequate, it would surely have been easy to have produced a better design.

Coming now to the contents, I am all admiration. There are some splendid examples of Palms of great size and in full health and vigour. One, a species of *Coccos*, was more than 50 feet high, and truly noble; *Latania borbonica* with its great shield-like leaves was also very large. So were several species of *Cycas*. We find here some noble tree Ferns, as *Cyathea elegans* and *serra*, 15 feet, with large and beautiful fronds, *Alsophila Cooperi*, &c.; but I must not particularise amongst so many. In addition to this there are other large houses for Palms, forming a portion of a long mixed range of rather lofty half-curved-roofed houses. In one of these is a specimen of *Phoenix dactylifera*, with a huge spreading head, and a stem upwards of 2 feet in diameter; *Chamærops Martiana*, 20 feet; and a fine specimen of *Chamærops chinensis*, or *Hemp Palm*, a very distinct and unique Palm. There were also very fine plants of *Corypha australis* and *Jubæa spectabilis*, the latter Dr. Moore stated to be quite hardy. I noticed here a fine plant of the *Bonaparteæ* in flower, which was very handsome. In another house were some fine Cactuses and a large plant of *Cereus Russellianus*; also a Mango tree laden with fine fruit, which, I was told, ripens off admirably. There were also some fine plants of *Brownea grandiceps* with their curious tufts of newly developed leaves, which give it such a singular aspect.

Although not, perhaps, in the order in which they stand, I next come to the Victoria house, having a ridge-and-furrow roof. The Lily looked well, the leaves were large, and it had several flowers. There were here several large plants of *Nepenthes*.

In other houses we find a fair collection of Orchids in good condition, and a great number of seedling *Nepenthes* and *Sarracénias*, than which there are no more beautiful and interesting plants, especially when in the young state. Next we enter a large New Holland house, where there is a fair collection of these plants, also of *Agaves*, *Sempervivums*, &c.

I have yet to notice one of Glasnevin's greatest features in the plant way—namely, its collection of tree Ferns. They are here in great quantity and variety, and for the most part looked well, but I fancied they would have liked a little more heat. In a small circular house there is a truly handsome specimen of *Cyathea medullaris* over 20 feet in height; there are also imported plants of *Alsophila australis* and *exelsa* with stems over 8 feet high. What must be the age of Ferns like these? If they do not produce stems more rapidly in their native country than with us, they must be very aged. A plant of *Cyathea debata* over twenty years of age, with Dr. Moore is only now beginning to form a stem: when will it be 20 feet high? This is in tree Fern house No. 2, where we find a large lot of fine fellows, as *Dicksonia antarctica* with a 5-foot stem grown at Glasnevin; another of the same branching into three stems; *Cyathea medullaris*, slender-foliaged; *Alsophila Cooperi*;

Dicksonia squarrosa, *C. Cunninghamii*, *C. Smithii*, and *Leichardtii*, all very distinct and graceful. How very noble these tree Ferns look, and how striking an effect have they in our plant houses when judiciously placed with other things! Outside, against the walls of one of these houses, I observed a very beautiful and, to me, strange plant for the situation. It was no less than *Clerodendron fœtidum*, with its great panicles of reddish purple flowers. It is there a hardy plant. In a little pond by the door I observed some fine examples of the *Limnæcharis Humboldtii* and the curious *Trapa natans*.

At the back of one of these ranges Dr. Moore is now erecting a lean-to having a northern exposure for the growth of *Hymenophyllums*, *Selaginellas*, *Todeas*, &c. There is to be a walk down the front of the house, then the bed about 8 feet wide up to the back wall, on which the plants will be placed in a slightly rustic style, and this then is enclosed by a glass partition formed of sliding moveable sashes, so that the plants are in a close glass case. This will be far better than the tiresome bell and hand-glasses, through which no one can ever see the plants. Dr. Moore has a choice collection of the above plants, which, when once properly displayed, will prove very attractive. In some low propagating pits I noticed many choice little things, and in particular a new *Anthurium* named *pedatum repandum*, and the pretty *Drosophyllums* and *Droceras*, or *Sundews*, wonderful in the extreme.

In the open ground I was pleased to find our old mixed border of herbaceous plants, which is always so full of interest. Here I noticed many choice gems which I should have liked to have called. The pretty little Daisy-like *Vittadenia trilobata* I had not before met with, although it is no new thing. In the front of the chief range of houses, and along each side of one of the main walks, this mixed border of herbaceous plants was continued, along with a very large and fine collection of *Saxifrages*.

Coniferae occupy a prominent place, and there are many interesting and fine specimens. *Abies Smithiana* was 25 feet high. There was a very large and fine plant of the *Golden Yew*, as well as a curious naked-growing form of *Cupressus californica* which I had not before met with. A Cedar of Goa had been raised from seeds which had been kept eighteen years—rather a remarkable instance of vitality in resinous seeds.

More and yet more I could tell of the treasures of this place, but I would just notice the fine collection of trees, Oaks especially, and one variety in particular, *Quercus Louettii*, truly a charming tree. In the nursery grounds attached, where Dr. Moore first proves the value of the trees and shrubs before putting them out in the grounds permanently, I observed many fine trees; one a Chestnut—*Castanea vesca pumila heterophylla*, was particularly striking. My attention was called here to an example of the *Orobanche* growing on the Ivy—not naturally, however, but, as Dr. Moore informed me, grafted on it purposely by Dr. Moore himself. It was growing with its usual character. I have never heard of this being done before. I look upon it as rather a horticultural triumph.

I hold Glasnevin in great estimation. It stands high in the list of botanical gardens, and it is pre-eminently a beautiful and enjoyable spot. Dublin may well be, as she is, proud of her Glasnevin, and of the high, honourable, and just estimation in which is held its talented director, Dr. Moore.—B.

THE NEW GLADIOLUSES OF 1870.

As several communications have reached me relative to our prospects of new Gladioli, I am sure that those few who know my excellent friend M. Sonchet will be glad to have some intelligence of him and his bulbs. I therefore subjoin a translation of some extracts from a letter I have just received from him.

“Up to this time our city has not suffered from the presence of the enemy in our country. Many columns of Prussian artillery, cavalry, and infantry have passed through our town without stopping there. They have not done us any injury, but all the country comprised within a radius of twenty leagues around Paris has been devastated. Our communications are often interrupted; but doubtless you are better informed concerning the events of the war than we are. We have no news of our friends living in the suburbs of Paris, especially of those who have left their homes. Where they are or what has happened to them we are utterly ignorant of. This anxiety, added to that of the final result of the bloody strife which we are now engaged in, and the cessation of the ravages wrought by the Prussians, sadly distress us. At the same time we have not

lost all spirit. Our courage, though shaken, will be restored, and, if time be given to us to complete and utilise our armament, men of earnestness will not be wanting to take the offensive. Unhappily our beautiful country is so disorganised and divided by party that our efforts are often paralysed.

"As for myself, I cannot regain my strength, and I had great difficulty in marking my Gladioli. I esteem myself very fortunate in having been able to take them up and store them in good time and in capital condition. Unfortunately, the war hinders our orders. We have been so harassed that I do not know whether I have sent you a list of my novelties, and therefore send one in this letter.

"If after the war we are enabled to execute any orders I shall be able to send out these novelties; but if not, I shall be obliged to call the novelties prepared for 1870-71 those for 1871-72.

"We hear that an armistice has been proposed by England. May God grant that it may be accepted, and that peace may be soon concluded."

He sends me a list with descriptions of the novelties coming out this autumn. There are in all twenty, bearing the following names:—

1. Aramis.—Rose, slightly shaded with orange and margined with cerise.
2. Athalie.—Violet, slightly shaded with rose; flamed purple.
3. Colbert.—Red cerise, slightly shaded orange.
4. Conde.—Reddish orange.
5. Coralie.—White, shaded rose and yellow.
6. Edith Dombriau.—White, very largely flamed with deep carmine, stained carmine purple.
7. Horace Vernet.—Brilliant red purple; pure large white stain, striped red.
8. Ida.—White ground, very slightly tinted with rose; flamed rose carmine.
9. Lamarek.—Cerise, slightly shaded orange.
- 10.—Nestor.—Clear yellow; lower petals deeper yellow striped with red.
11. Phidias.—Very brilliant purple, slightly tinted violet; large pure white stains, finely striped with carmine cerise.
12. Phire.—Ground pure white, largely bordered and flamed rose.
13. Primature.—Very long spike of rose-coloured flowers, slightly tinted with lilac; flamed bright carmine.
14. Redonete.—Beautiful rose, slightly tinted with violet.
- 15.—Sappho.—Very beautiful cerise colour, shaded orange.
16. Sir J. Franklin.—Very beautiful satiny rose; all the petals lined white.
17. Talisman.—Beautiful violet, largely bordered with bright cerise.
18. Van Spanlowk.—Very striking red.
19. Zelinda.—Very beautiful bright rose; largely flamed deep carmine.
20. Zenobia.—Rose, very slightly tinted with violet; flamed deep carmine.

Of these 6, 7, 11, 12, 13, 15, 16, and 17, seem from their price to be the best; but we must wait, for not seldom we are obliged to reverse the decision come to on the other side of the Channel.—D., *Deal*.

PLANTING WHOLE POTATOES.

A NEIGHBOUR of mine, whom I will call B, and I, each invested last spring in a hundredweight of Paterson's Victoria Potatoes. They were very large, so B decided to cut his in two, but I preferred planting mine whole. I wrote to you on the subject last June, and you replied to me in your number of the 2nd July, page 16, requesting me to let you know the result. I now do so.

The cut and uncut sets were planted in the same field side by side, and equally manured. It was a very long field, and as my uncut sets were sufficient to plant one row, of course B's planted two rows. My row yielded 8 cwt., and B's two rows yielded only 7 cwt. between them. I conclude, therefore, that by cutting his sets instead of buying another cwt. to plant in the second row, that B lost 9 cwt. of Potatoes, or the sum of 40s., calculating them at 5s. per cwt., the price we gave, and allowing for the extra cwt. for sets.

Many of the cut sets missed owing to the dry season, and although B does not think the trial a fair one, he says he means to plant whole ones in future.

Mr. Fenn and most of the authorities on Potato culture advise planting whole Potatoes, but the accounts you have lately been publishing of the yields of the Early Rose and Bovinia Potato sets cut into the smallest pieces are sufficient to shake anyone's faith in the practice. One gentleman cut a Potato of 1 lb. weight into nineteen sets, the produce being

133 lbs. Query, If this Potato had been set whole in a hill with plenty of room, would the produce have been greater? This question wants ventilating. Will some of your correspondents give us the benefit of their experience?—CALCRIA.

MAIDSTONE GARDENERS' IMPROVEMENT ASSOCIATION.

SEVEN or eight years ago a few gardeners in the neighbourhood of Maidstone met, with the view of making arrangements to secure a room in which they might assemble at stated intervals and discuss subjects connected with their calling. A number of members enrolled themselves in what was called the Maidstone Gardeners' Mutual Improvement Society, and a set of simple rules was framed, one of which stated that a general meeting was to be held once a-month, and an ordinary meeting in the intervals between the general meetings. At both plants, fruits, vegetables, or anything connected with gardening might be shown by members and commented upon; or any gardening subject might be brought forward by a member on giving proper notice, and every facility was given for any member disposed to speak, some officer of the Society occupying the chair.

The success which attended these meetings was very great, and the interest taken in the matter by others not connected with gardening led many to become honorary members, so the Society resolved in the winter of the second year of its existence to hold a show, or rather arrange a display of plants, fruits, and vegetables in the Corn Exchange, the largest building in the town. To render it more attractive, the room was decorated with wreaths of evergreen, and other horticultural devices, and a small charge being made for admission to non-members, a handsome sum was added to the funds of the Society. Its importance seemed now to have outgrown the few simple rules at first framed for its guidance, and a new set was prepared, which, amongst other clauses, empowered the Society to afford its members pecuniary assistance to a limited extent when overtaken with sickness, and to grant a sum not exceeding £10 to the representative of a member at his death. In addition, when the funds would allow, the sum of £20 was to be apportioned for the Society having a holiday somewhere once a-year. Now the latter two items seemed large sums from a Society that only required a subscription of 4s. a-year from its members, yet such has been its success that it has always met its engagements, and I believe at the present moment it has between £200 and £300 in hand, although death has called off three or four of its members, each of whom have had the sum I have stated, and the yearly holidays have always been carried out in the summer. Thrice the excursion was to the Crystal Palace, once to Hampton Court, and once to Kew, terms being made with the railway company to take the Society at a stipulated price, the members paying about 1s., and the others 4s. for their tickets, and heavily loaded trains have always been the result.

If this could be done in a town like Maidstone with scarcely 25,000 inhabitants, the question naturally arises, Can it not be done elsewhere? The Society has every spring held a show in the Corn Exchange without giving prizes, it being simply an exhibition in which everything is arranged for effect. Vases, extempore fountains, and other things are fitted up by willing hands under the superintendence of an arrangement committee, and every season a change is made in the arrangement. Music is also provided; and as the exhibition is kept open in the evening, the working classes of Maidstone and its suburbs have an opportunity of seeing it, and are no doubt stimulated by the example, for more than one of the neighbouring villages has its Gardeners' Mutual Improvement Association, where meetings in some degree similar to those of the parent society take place.

The exhibitions generally attract many visitors, and the sum of £100 has been taken at the door on one occasion, but of course there is considerable expense; still, there is always a surplus, which goes to the funds of the Society.

It is, however, the monthly meetings, when matters relating to horticulture are discussed, that appear more than anything to have given the Society so firm a hold of public support. At these meetings it is usual for the President of the Society to take the chair, and as notice has been given at the preceding meeting of what is to be brought forward—generally two or three subjects—one of them is opened up by the person who gave notice of it, and discussion generally follows. It is also not unusual for members to bring fruits and other productions to obtain

the names and other information from more experienced members. These meetings are usually well attended, from forty to double that number being often present, and on special occasions more than that. The Society, I believe, consists of upwards of four hundred members, nearly one-half being immediately connected with gardening, and classed as gardeners; the others are honorary members. Mr. Frost, formerly gardener at Preston Hall, but now a nurseryman in Maidstone, is President. The other officers are chosen from gardeners of good standing in the district, and I believe that all has hitherto worked well, which is much to say of any society. The good feeling shown towards the Society, coupled with the prudent counsels of some of its chief officers, have so far prevented anything like discord, and financially, as well as in other respects, the Society stands in a better position than it ever did.

These observations, explanatory of the working of the Society, are intended to introduce to the readers of THE JOURNAL OF HORTICULTURE another move the Society has made. The previous exhibitions have always been held in the spring, when plants were the principal attraction, and the show of last April certainly exhibited no falling-off from those of former years; but it was thought an autumn fruit show would be an acquisition, and accordingly one was arranged for October 12th, and was in every respect a success, upwards of 1200 dishes of fruit being set up, representing everything of the kind to be met with at a metropolitan show, and many of them in as high a degree of perfection as they well could be. The Apples and Pears were especially fine, as might be expected in a county where so many are grown. One grower sent fifty-two dishes of Pears, all different, and about half that number of Apples; another had upwards of eighty dishes of fruit all carefully named; while smaller contributions were no less commendable by their quality, size, and perfection. Not the least remarkable objects in the Show were the excellent samples of out-door Grapes, and still finer bunches were exhibited from under glass. The Show also comprised Pines, Peaches, Plums, and Damsons, Melons, Figs, Cherries, Strawberries (from the open fields), Raspberries, Gooseberries, Currants, Quinces, and Medlars, as well as Apples, Pears, and Grapes, and some rarities, as Bananas, fruit of the Passion-flower, &c., and two or three exhibitors had dishes of Apples of 1869 in good preservation. Vegetables were equally well represented. Mr. William Luckhurst, at Lord Romney's, The Mote, sent an excellent collection, as also did Mr. Lee, gardener to J. Whatman, Esq., M.P., while the contributions from others were not less remarkable. Plants were but sparingly introduced, only a few being placed along the centre of the tables in the middle of the room to divide the collections. The vegetables occupied the side tables. Taken altogether, the Show might be regarded as one of hardy fruits, such as few districts could furnish, and one of which the members of the Maidstone Gardeners' Mutual Improvement Society felt a little proud, for 1200 dishes of fruit are not collected together every day.—J. ROBSON.

PITCHER-PLANTS.

DIFFERENCE of opinion has been expressed as to the nature and use of the liquid found in the so-called pitchers of various plants, such as *Nepenthes*, *Rafflesia*, and certain *Orchidaceæ*. The popular idea that these curious receptacles collect pure water for the refreshment of the thirsty in arid places, would seem to be set at rest by the consideration of the fact that these plants grow in moist and marshy places. There would seem, moreover, to be some improbability that plants should secrete pure water.

In this country, where these plants are grown under exceptional conditions, there is some difficulty in settling these questions experimentally. In such cases extraneous water often finds its way into the pitchers, so that several ounces may frequently be gathered from a single receptacle of *Nepenthes*, the greater part of which is accidental.

In August last I had an opportunity of collecting the liquid from two flowers of *Coryanthes*, one of the *Orchidaceæ*, which had just opened, in one of the well-known stove houses of Mr. Wilson Saunders.

Though the quantity collected was small, amounting only to about 3 cubic centimetres, or 1.18 cubic inches, an examination showed the following properties:—

Clear and somewhat glutinous in consistence. Possessed of a high refractive power, and a specific gravity of 1.062.

Oudour pleasant but faint, becoming more marked by a gentle heat. Neutral to test papers. Becoming milky, by concentra-

tion on the water-bath, it finally yielded a transparent gum insoluble in alcohol.

Oxalates produced no precipitate of lime, but basic lead acetate gave a curdy reaction. Concentrated hot sulphuric acid blackened the liquid.

Although the taste was not acrid, the mawkish flavour would render it quite unpotable.

This examination therefore proved the liquid to be something else than pure water.

100 parts of liquid contained:—

Water and volatile oils	98.51
Non-volatile residue.....	1.49
	100.00

—G. B. BUCKTON.—(Nature.)

CONSTRUCTING AN ICE-HOUSE.

ABOUT three years ago my employer wanted to do away with the ice-house. It was too near the residence. He thought he should like a square one. I showed him the sketch of that in one of your numbers of July, 1864, and he thought it was just the house he should like. We set to work and had it built, and we have filled it twice, but when we came to open the house, which we do not want to do until about the second week in November, there was not a bit of ice left either time. Of course, it is a great disappointment. I see that the sketch in your Journal is by Mr. Fish; if he would give me his advice I should be obliged. You will see by the accompanying outline of the house (which is 10 feet wide, 14 feet long, and 9 feet deep), that I have had a drain pipe put in at each corner, so that the air may pass all round between the walls. The roof does not come to the ground, for I have the air passing in and out by the sides.—G. Y. M.

a, a, Outside 9 inch wall.
 b, b, Inside 4½-inch wall.
 c, c, Well all below ground.
 d, Arch.
 e, e, Drain-pipe.
 f, f, Roof.
 g, g, Drain.

[We are sometimes asked the cause of failures, when we can give no better reason than that known to the inquirers, and thus we are often reminded how little we know. In the present case we feel rather pleased, not that there has been a disappointment, but that we think we see how it may be prevented in future.

We may first remark, that it is next to folly to suppose that in wells whether circular or square, or even in stacks above ground, ice can be long kept in small quantities. This is trying to an ice-house not opened until November. The house described is rather small for such late work. We should have

liked it better if it had been 14 feet square, instead of 11 by 10, and as much in depth, instead of 9 feet. However, the size is not the chief cause of failure. That we believe is owing to the free access of the air in summer all round between the outer and the inner wall. The heat of the surrounding ground, and the heat of the warmest air in July and August, have thus had free play on the 9-inch wall surrounding the ice. For practical purposes, the ice-house might almost as well have been a building with a 9-inch wall above ground. The great advantage of the double wall is to enclose a body of *still* air, and then that air is a non-conductor of heat. It loses that quality when it is not confined. We would first, then, shut up *all* the air-openings between the two walls; in fact, be quite as anxious to keep a breath of fresh air from getting there, unless, indeed, it were a severe frost, as you would be to admit air into your own bedroom. It is on the complete isolation of that air that its non-conducting power depends.

Secondly, if the roof does not extend to the ground, bring it over the outside wall so that the drip shall fall considerably beyond it. Thirdly, in such a house we would use no straw for packing, but pack the ice at once against the inside wall. When finished we would place a layer of clean dry straw on the surface. As the days lengthened in spring we would open the house, and if the straw were at all damp we would remove it and replace it with fresher, and do so again if necessary.

If, as the days became very warm, on opening the ice-house there should be any appearance of misty vapour, which sets rapidly on ice, we would have one or two small openings in the top of the doorway, say an inch in diameter, furnished with a cork so as to let this vapour out when present, and keep the holes shut when there was no vapour. A pipe coming out at the roof would even be better to be stopped at pleasure. In a house of the size referred to, keeping ice will greatly depend on having the air over the ice dry, whilst the ice itself is not directly exposed to it. We believe the chief cause of failure is the air moving in the open space between the two walls. We presume the drain from the bottom is trapped.—R. F.

STOKE NEWINGTON CHRYSANTHEMUM SOCIETY.

This Society's twenty-fourth annual Show was held on the 15th and 16th inst., in the New Assembly Rooms, Detoe Road, Stoke Newington. The specimen plants were arranged in the orchestra, and there proved very effective as a whole, while individually they were without exception of high excellence, as may be imagined from the fact of several of them having from seventy to eighty blooms. The best six came from Mr. Drain, Southgate Nursery, De Beauvoir Town, and consisted of Prince Albert, Annie Salter, Christine, Little Harry, Alma, and Mrs. G. Randle. Mr. Forsyth, of the Brunswick Nursery, was second, with fine plants of Golden Christine, Mrs. G. Randle, Dr. Sharpe, Prince of Wales, Lady Harding, and Annie Salter. The third prize went to Mr. Little, Cambridge Park, Twickenham, who had tall-stemmed plants, which are less effective as specimens, but with very fine blooms. For three plants Mr. Drain was again first with Mrs. G. Randle, Dr. Sharpe, and Prince of Wales, Mr. Forsyth being second.

The specimen Pompons shown in Classes 3 and 4, respectively for six and three plants, were also excellent. Mr. North, Manor Lane, Lee, and Mr. Forsyth, had the best sixes, consisting of the different kinds of Cedo Nulli, Bob, Salomon, and Golden Circle. Several of these plants were a yard across, and a mass of bloom. Mr. Monk was third. The prizes for three plants went to Messrs. Monk, Butcher, and Forsyth. Standard Pompons, as shown by Mr. Howe, of Shacklewell, were admirably grown and bloomed. They were about 4 feet high, and with heads nearly a yard across. The varieties were Bob, White and Lilac Cedo Nulli, Mustapha, Golden Aurore, and Antonius. Messrs. Monk and James were respectively second and third.

Cut blooms were very well shown, perhaps on the whole not so large as in some years, with the exception of White Globe, Queen of England, Empress of India, and a few others; but the blooms shown by Messrs. Rowe, Slade, and Monk were not only of remarkable size, but very perfect. The first prize for twenty-four was taken by Mr. Rowe, of Roehampton, with Empress of India, Prince Alfred, Princess of Wales, Bronze Jardin des Plantes, White Globe, John Salter, Queen of England, Prince of Wales, Mr. Gladstone, Plutus, Nonpareil, Lady Slade, and others also fine, though those named were the most conspicuous. The other prizetakers were Mr. Slade, Mr. Sanderson, and Mr. Drain.

For twelve blooms Mr. Rowe was also first with magnificent

examples of Empress of India, White Globe, Queen of England, Prince Alfred, Miss Mary Morgan, Lady Slade, Nonpareil, Rev. Joshua Dix, Empress Eugénie, Prince of Wales, Princess of Teck, and Jardin des Plantes. Mr. Monk, who was second, had also a very fine stand.

SUBSTITUTE FOR GRAFTING WAX.

Not long ago, the Mastic l'homme Lefort, or cold grafting wax, was first brought under our notice, and this we have found exceedingly handy when grafting small things, on account of its being ready for use at all times. Latterly we have been using another material, which for certain purposes is infinitely more handy, superseding, indeed, not only the grafting wax, but the very matting or string by which we tie graft and stock together. This material is nothing more nor less than sheet indiarubber. It was Major Clarke, than whom there is no greater nor more original horticultural experimentalist, who first called our attention to it, and it is really very wonderful how handy it is. Indiarubber may be purchased, in sheets of about the thickness of brown paper at some of the London shops which deal in articles of that class for a mere trifle—6d. or 1s. the square foot. The undressed sheets are the best. Before using it wash it in clean water, and dry it by dabbing it with a handkerchief or cloth.

The sheets are cut as required into pieces of about an inch in length, and about an eighth of an inch in width, according to the space to be covered, and the little band so formed is twisted round in the same way as a piece of matting would be, and, of course, elongates considerably, encompassing the stem two or three times. The end is simply yet securely fastened, by just pressing it firmly into the other with the thumb nail. This forms it into a simple elastic band, which keeps its hold as long as required. For grafting choice little enjoints, and for delicate operations, the small strips of sheet indiarubber are extremely handy and useful, and far more easily fitted than a piece of matting.—A. F. BARRON.—(*Florist and Pomologist.*)

PAULLINIA SORBILIS.—In a recent number of the *Pharmaceutical Journal* a paper appears, by Mr. Cook, on the Guarana, the seeds of a tree termed the Paullinia sorbilis, belonging to the order Sapindaceæ, and abundant in the province of the Amazonas. The fruit is scarcely as large as a walnut, and contains five or six seeds, which are roasted, then mixed with water and moulded into a cylindrical form resembling a large sausage, and finally dried in an oven. Before being used it is grated into a powder, very like powdered cacao in appearance. Two spoonfuls of the powder are mixed in a tumbler of water, and this drink is regarded as a stimulant to the nerves, and like strong tea or coffee, is said to take away the disposition to sleep. The active chemical principle is an alkaloid, which Dr. Stephenson has shown to be identical with theine. Guarana contains more than double as much of this alkaloid as good black tea, and five times as much as coffee, the proportion being 5.07 per cent. in Guarana. It is rather a singular coincidence that the same alkaloid should prevail in all the principal substances employed in a similar manner as beverages in different parts of the world, in the tea of China and India, the coffee of Arabia, the cacao of Central America, the maté of South America, and the Guarana of Brazil. Guarana is a nervous stimulative and restorative.—(*Nature*)

NOVEMBER CATERPILLARS.

The entomologist has many opportunities for verifying the popular proverb, that "in looking for one thing you find another," so often does he go out intent upon discovering some insect, the locality of which he thinks he knows, and while he fails to get this, lights upon other species he did not dream of finding. Also, while searching for insects in one particular stage, specimens turn up in other stages; when hunting for imagos especially we come across caterpillars, and if seeking caterpillars we very frequently discover chrysalides. Amongst other choice chrysalides taken this month, by what we call a fortunate accident, the insect-hunter, between united leaves of Birch, Beech, or Oak, finds the cocoon of the Lobster Moth, the caterpillar of which we described last month. The chrysalis is without any notable singularity.

The cabinet of the entomologist is not likely to derive much advantage from his researches among the caterpillars in November, for though there are a few which may be taken now

nearly full-fed, and do not require much care or attention to bring them through, the bulk of the hibernating individuals, if brought in-doors, or otherwise placed in confinement, are difficult to rear. But still, those who desire to gain a thorough insight into caterpillar history will devote themselves, as opportunity offers, to the work of seeking for colonies, or isolated individuals, even at a season when such a pursuit is less attractive than in the summer season. And there are certain species, it must be remembered, which may be detected in winter, when the trees are bare and herbage is scant, with more facility than when vegetable life is at its height. Ingenious, too, as are the modes of concealment adopted by some hibernating caterpillars, they ought not to baffle the determined collector entirely, though he may require several successive seasons to pass by ere he can say that he has succeeded in fully elucidating the life-history of some one or other of these.

Amongst these hibernators is one to whose peculiarities I have paid much attention, having at various times reared a large number of the caterpillars. This produces the Moth known as the Scarce Vapourer (*Orygia gonostigma*), and the species is highly interesting because it is so closely allied to the very common Vapourer Moth, which we see dashing wildly about in London suburbs, and in the vicinity of other towns during the summer. The other species is confined to a very few localities, one of which is in Surrey, near the metropolis; and as the female moth is destitute of wings, and cannot journey from place to place, it is not likely to become more common. The caterpillar, by the movements of which alone could it be distributed, is not very migratory; and the circumstance that it lives through the winter, exposes it to various dangers which the common species escapes, since through the cold months it is in the egg state. The caterpillars of the Scarce Vapourer are hatched about the end of July, from eggs deposited in a cluster (sometimes as many as four hundred); and at first emergence they keep pretty closely together, separating from each other by degrees as they increase in size, but they grow very slowly, and soon prepare to hibernate. As is the case with other species, they do not always locate themselves for the winter on or near their food plant, which renders a search for them more difficult. According to my observations, they do not form any protection for themselves, usually resting near the ground on a twig near the centre of a bush. In some cases, they have been found actually on the earth, and observers have reported also instances where these caterpillars had sheltered themselves by weaving a web around a leaf or branch, but this is probably exceptional. Remaining without food until the spring, the caterpillars of the Scarce Vapourer are quite ready in April to commence an attack upon the Sallow or Hawthorn buds, taking afterwards to the Oak or Hazel, which they prefer. The ground colour is a beautiful orange with four rows of black spots coalescing so as to form stripes; from the fifth to the eighth segment we find a brown upright tuft of hair arising from each; the second segment has two long pencils of hairs which point forwards; on the last segment there are three tufts of black hairs, directed backwards. A considerable portion of the hairs are used by the caterpillar in forming its cocoon, and the chrysalis is also hairy.

A very local moth is that called by collectors the Reed Leopard (*Microgaster arundinis*), and it is one of those species which beguile the insect-hunter into the uninviting fenny districts of Huntingdonshire and Cambridgeshire. Like the Swallow-tail Butterfly, each year tends to diminish the numbers occurring, through the reclaiming of the fens. The caterpillar lives from summer until the following spring, and probably feeds through the winter unless in severe weather. It is of a dirty white colour, with a horny head, and a plate of similar texture on the next segment, very much resembling a maggot in appearance. The egg is deposited by the mother moth on the stem of the common Reed, only one being laid on each plant. The young caterpillar at once eats its way to the interior of the stem, and generally works its way upward towards the top of the plant, though it has the power of moving up and down. The chrysalis is long, and has rows of minute hooks, by means of which it is able to change its position if needful, giving birth to the moth in June.

The history of the Black-veined White Butterfly (*Aporia crataegi*) is very interesting. Classified, as it is, with the common Whites, and bearing a resemblance to them in some particulars, it is much scarcer, and differs greatly in its habits. The caterpillars, directly they are hatched, construct a sort of tent, under which they feed, but do not attain any considerable size during the autumn. A similar, though thicker, tent serves

them for an abode through the winter season, when the prying eye of the entomologist, scanning the boughs of the Hawthorn or the Pear, may perhaps discover it, and carry off the colony as a prize. Certain districts in Wales and contiguous English counties yield this species most abundantly in some seasons, and it occurs in Kent near Faversham, and also, it is said, in Devonshire. The caterpillar of the Black-veined White, when full grown, has the head of a smoky black, covered with hairs of two different lengths, the shorter being black, the longer white. The body is a rather deeper black, and it has two rust-coloured stripes, which a moderate magnifying power resolves at once into a number of minute spots; in the centre of each of these there is a black dot, from which springs a rust-coloured hair. Underneath, the surface of the body is grey, sprinkled with black dots, and dotted with whitish hairs. When full-fed, this caterpillar spreads a silken web over the twig on which it has been feeding, and, fixing itself thereto, turns to a chrysalis. Sometimes, however, like its relatives the Whites, it will crawl from the tree or shrub to some wall or paling. The butterfly, which appears in July, flies swiftly by day, but at night is easily taken in those places where it occurs as it rests on the flowers in full view.

A particularly local butterfly is that pretty species the Marbled White (*Argo Galathea*), and as it very seldom flies far beyond the meadow where it was bred, there is some encouragement for the collector to look for the caterpillar, which feeds upon various grasses. It is but small when it hibernates, remaining apparently without eating all through the winter, though some species, also grass-feeders, nibble the blades occasionally if the weather is mild. When feeding, at the least annoyance or alarm the caterpillar of the Marbled White falls from the plant in a curved posture, lying without motion for some time. The head is rough, sometimes green, sometimes brown; the hue of the body also varies similarly, but always a little darker than the head; down the middle of the back is a dark stripe, on each side of this is a narrow stripe, pale red, and just below the spiracles (which are deep black) there is a whitish stripe. The body is stout, rather fusiform, and at the anal extremity exhibits two points, in which all the stripes meet; every part is studded with minute warts and short hairs. No preparation for becoming a chrysalis appears to be made by this caterpillar; descending from its food-plant, it settles low down amongst the herbage, and turns to a short brown chrysalis, partly transparent, from which the perfect insect soon emerges.

In places where the common Broom grows plentifully, we are almost sure to find in November, and through the winter, the young caterpillars of the Grass Emerald (*Pseudoteipna ctyisaria*). Hatched during July, they grow but little in the autumn, and then fix themselves upon the stems of the plant, and with the head raised from the surface they remain unmoved in the coldest weather, re-awakening to life about the end of April. When getting near their full size they rest on the twigs in a singular position, with the head bent under and the legs crowded together and brought close to the mouth. The whole body is covered with small points, as if shagreened, the head being deeply notched on the crown, while from the segment behind it rise two blunt protuberances, which point over the head; on the last segment are two points of a pinkish hue. The general colour of both head and body is dull green, with pink on the crown of the head and the protuberances behind it; a very narrow brownish stripe runs down the back, and along each side is a white stripe, edged with red, which is interrupted on the fourth segment; the spiracles show distinctly, being paler than the ground colour. When these caterpillars have ceased to feed they draw two or three leaves loosely together, and under this shelter become chrysalides about the end of June.

Another hibernating geometer caterpillar, which bears some resemblance to the preceding, is that of the Common Marbled Carpet (*Cidaria russata*); unlike it, however, it feeds occasionally during the winter in mild weather, being then found upon or near the wild Strawberry, in the summer it has also been detected on Birch and Sallow. This caterpillar rests usually with the body extended, but, if touched, at once raises its head and bends it under, in the "volute form." The head is of a rather duller colour than the body, the eyes, which are black, showing conspicuously; the body pale yellow-green, with a stripe of dark green down the back. In some specimens there is a beautiful purplish stripe along the sides. All over the body are minute white warts, each giving off a hair; at the anal extremity are two protuberances, usually rose colour; the legs and claspers are of a dull red colour. The individuals of this

species which have lived through the winter turn to chrysalides in May, and there is a second brood of the caterpillars in June and July.

The curious caterpillar of the Scalloped Bar (*Scodiora Belgaria*) occurs on heath, and is rather uncommon. It may be looked for at this time on patches of the common Ling, near the roots of which it remains in a state of hibernation, rousing itself to eat in April. When alarmed it rolls into a ring, and will remain thus coiled up for an hour. In colour it is brown, with indistinct greyish markings, and a short white stripe near the first pair of claspers. On each segment there are two warts on the back, and there is a conical short horn above the anus, behind which are two longer and slender horns, which are usually pressed closely together. The female caterpillars are perceptibly less in size than the males, a rather unusual circumstance. The cocoon is spun upon the ground; it is of slight texture.

On various heaths and commons, though less abundant now than formerly, we find the caterpillar of the Clouded Buff (*Euthemonia russula*), which, though hatched from the egg in July, does not become adult till the following May. Its favourite food-plants are the Monse-ear Hawkweed and the common Dandelion. At this time it is about one-third grown, and is dull brown in colour, with hairs of a reddish brown, and a faintly indicated stripe down the back. When the weather is favourable it appears to feed on various low plants, as does also the caterpillar of its handsome relative, the Wood Tiger (*Chelonia plantagenis*), so named from its partiality to plantain. Clearings in woods yield this species, especially in the south, and the caterpillar may be detected in the winter season by the persevering insect-hunter. It is of a greyish black tint, dotted over with numerous warts, and covered with long hairs, which increase in length towards the anal extremity, being black in colour at the head and tail, and reddish brown on the middle segments. In its habits it appears very sluggish, and is also the moth, which is rarely seen on the wing.—J. R. S. CLIFFORD. —(*English Mechanic and World of Science*.)

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

ENOTHERA WHITNEYI (Whitney's Evening Primrose). *Nat. ord.*, *Scrophulariaceae*. *Limn.*, *Ocoteandia Monogynia*.—"The most splendid of all the species." Flowers pale pink, blotched towards the claws of the petals with purplish crimson. Native of Shelter Cove, Humboldt County, California.—(*Bot. Mag.*, t. 5867.)

SERAPIAS CORDIGERA (Heart-lipped Serapias). *SERAPIAS LINGUA* (Tongue-lipped Serapias). *Nat. ord.*, *Orchidaceae*. *Limn.*, *Gynandria Monandria*.—Natives of all the countries bordering the Mediterranean except Egypt. Flowers deep French white; lip of *S. cordigera* dark purple; and of *S. lingua* crimson.—(*Ibid.*, t. 5868.)

ARISTOLOCHIA BARBATA (Bearded Birthwort). *Nat. ord.*, *Aristolochiaceae*. *Limn.*, *Gynandria Hexandria*.—Native of Venezuela. A very graceful twiner. Flowers pale green and reddish brown, lip clothed inside with purple bristles like a beard.—(*Ibid.*, t. 5869.)

GREVILLEA BANKSI (Sir Joseph Banks' Grevillea). *Nat. ord.*, *Proteaceae*. *Limn.*, *Tetrandria Monogynia*.—Native of barren hills in Queensland, Australia. Flowers crimson and yellow.—(*Ibid.*, t. 5870.)

DODECATELON MEADIA var. *FRIGIDUM* (Arctic American Cow-slip, or Shooting Star). *Nat. ord.*, *Primulaceae*. *Limn.*, *Pentandria Monogynia*.—Native of mountain slopes from latitude 35° N., in California to the Arctic seacoast. Its flowers are usually lilac and white, but sometimes crimson and white, and even entirely white.—(*Ibid.*, t. 5871.)

ALPINE AURICULAS.—*John Leech*, *Selina*, and *Monarch*.—"Seedling Alpine Auriculas have been one of the specialties which, during the last three or four years, Mr. Turner, of Slough, has been in the habit of exhibiting at the spring shows at South Kensington; and rich and varied in colouring as they are, it is no matter of wonder that they should generally have acted on the admiring crowd as one of the principal centres of attraction. Certainly, few groups of flowers could have been more truly beautiful, while in their beauty few could have more thoroughly combined the elements of simplicity and gaiety; and when to this is added the fact that improvement is manifestly going on amongst them, form and colour proportions being moulded to the florist's standard, who can wonder that the Alpine Auriculas (with the self, perhaps) should, on ac-

count of their more decided and richer hues, prove more popular, at least in general public assemblies, than their grotesque brethren, the greens, the whites, and the greys?—though even these we are glad to see meet with more attention and more admiration than they did a few years ago, and might probably again become popular, if growers could be induced to cultivate them, and exhibit them more freely.

"*John Leech* is a rich shaded crimson, smooth, and well proportioned, and one of the richest flowers in its class. *Selina* is a velvety shaded purple, with white paste, and in this feature approaching the ordinary self-coloured varieties. *Monarch* is another purple, with rich shading, and of remarkably fine shape and proportions, doubtless one of the best in its class.

"Not only on account of their highly-coloured and richly-shaded flowers, and the lively contrast afforded by the usually yellow colour of the paste, but also on account of their more vigorous constitution and freer habit of growth, these Alpine Auriculas are likely to rise in popular favour."—(*Florist and Pomologist*, 3 s., iii., 241.)

NIGHT SOIL AS A MANURE.

I NOTICED in last week's Journal that, in answer to an inquiry of one of your correspondents, you spoke very highly of night soil as a manure. This induces me to ask your kind assistance to enable me to overcome a difficulty I experienced last summer through using night soil. I purchased one of the recently-patented "earth closets," the soil from which I applied to my Cabbages, a portion of one of my Onion beds, and a row of Scarlet Runners, and nothing could exceed the very favourable appearance of these crops at first, as they were very considerably in advance of crops planted at the same time, to which I had put stable dung only; but on approaching maturity I first noticed several of my Cabbages begin to droop, and on pulling them up to ascertain the cause, found that the whole of the root had been eaten away by a small white maggot, and nearly the whole crop of Cabbages, Onions, and Beans, to which this manure had been applied, was destroyed by them. I should, therefore much esteem any assistance you may be able to afford me with a view to preventing this.—HOWARD.

[We do not think that the night soil caused the occurrence of the white maggots, but the protracted dry season. Watering and mulching over the roots on each side of the Scarlet Runners, and copious waterings of the Cabbages and of the Onions after the bulbs began to swell, would have kept away the maggots. We grow Onions in rows, with a gutter between each two rows, and in those gutters we pour about once a-week house sewage mixed with water.—EDS.]

THE PLANTING AND LAYING-OUT OF THE THAMES EMBANKMENT NORTH.

SOME of our readers may remember that portion of the north bank of the Thames which extended from Whitehall Stairs to Waterloo Bridge; and those of them who are ignorant of the former condition of that now-transformed region will, perhaps, care to be told that it was a wide extent of malarious mud, varied here and there by the hulks of dilapidated barges, the carcasses of dead dogs, and sundry other articles which go to make up the flotsam and jetsam of our great tidal river. Why that great mudbank should have been suffered to exist so long after civilisation was supposed to have been introduced among us some member of the Thames Conservancy Board may, perhaps, be able to enlighten us; but the only apparent object of the mud conservancy was that it might afford a source of fun and recreation to the herd of mudlarks who burrowed in the Adelphi Arches, and sought shelter in the stairs and passages of old Hungerford Market, much as parks and pleasure grounds are reserved in the present day for the health and recreation of the population. What high holiday these little mudlarks enjoyed! It was perpetual holiday with them. It mattered not what heavy thoughts weighed down the careful city man as he passed along the old shaly barge-borne gangway to the "penny boats," the little mudlark, gambolling in what seemed his native element, bailed him with his cheery though inexpressibly dirty face, grinning from ear to ear, and with the winning request, "Chuck us a penny, sir," he melted the moody man into acquiescence. Oh, the effect of that "chuck!" Away went half a dozen ragged little rascals up to the thighs in black ooze, straight as arrows to their mark. Then came the struggle, the pushing, and the wrangling, and at last the coveted

prize was gained frequently not without a disputed ownership which ended in a general scrimmage.

But those days, like all "good old days," are gone, and the mudbank and mud-larks with them. The Metropolitan Board of Works has covered over the mud in making the Thames Embankment, and the mud-larks, let us hope, have either become industrious eboelacks or enterprising colonists. And where the mud was, the genius of gardening has taken possession. Within these few months, under the direction of Mr. McKenzie, and in execution of his design, a garden has been formed, of which we this day furnish a plan, and which already adds to the beauty and ornamentation of the Victoria Embankment. The design, which is Mr. McKenzie's, has been executed by Mr. Meeton, and we congratulate both on the manner in which they have severally carried out the work.

That work has been executed in accordance with the propositions contained in the following report made by Mr. McKenzie on January 27th of the present year:—

"I may state, at the outset, that I have avoided everything in the way of expensive gardening, and where a doubt exists as to the ultimate use of the reclaimed ground, I have endeavoured to submit a plan, which, if carried out will be effective at the present time, and capable of being cut up ultimately without a total disfigurement of the works proposed to be executed at this time. Of course, a much more expensive system of gardening might be introduced, without much alteration to the design, by the introduction of statues, fountains, and vases.

"The walks are so arranged as to give facility to the public from each of the recognised entrances, with a pleasant and diversified plantation on either side, at the same time preserving enough space for grass, which, in all cases ought to be well kept.

"The plantations, although nearly continuous, are sufficiently broken to give glimpses from the embankment roadway at such points as the breadth of the views will justify this being done.

"The nature of the plantations will be more expensive than that at either of the parks [Southwark and Finsbury] for two reasons. First, the nature of the surroundings, so far as the Metropolitan Board of Works is concerned, is so much richer than anything surrounding either of the parks, that a different class of trees and shrubs will be required to dress the ground. Secondly, the variety of trees and shrubs suitable is much reduced, owing to the growth of many varieties being destroyed by the influence of smoke and other causes inseparable from the position.

"The planting should be to a considerable extent of deciduous trees and shrubs; their beauty and brilliancy of foliage in spring will compensate to a great extent for the absence of foliage in winter, which is seldom bright, except after heavy rains. Thus, I should recommend the plantations to consist of groupings of Laburnums, Acacias, flowering Almonds, double-flowering Peaches, and other rosaceous trees; of double and single Thorns in groups of colours: also groups of trees conspicuous for their colour or variety of foliage, such as Copper Beech, Acer Negundo variegatum, &c., and filling up between with evergreens to give variety in winter, so as to afford interest to the plantations at all seasons of the year.

"Generally speaking, the plantations should consist of permanent plants, but I think it will be impossible to give general satisfaction without a few patches of flowers judiciously and sparingly dotted about.

"In dealing with the ground, I have endeavoured as far as possible to adapt the design to future requirements.

"In dealing with the Buckingham Gate, it will be necessary to lower the walk leading to it by throwing up banks on either side, owing to the gate itself being so much below the level. It would, however, very greatly improve the appearance if the gate were brought up to the level of the Buckingham Street roadway.

"In the formation of the ornamental grounds, I think it is of great importance that a water-pipe with hydrants be laid throughout the whole length, so as to be able to water when necessary, and wash and refresh the foliage, as so much depends on the beauty and health of the trees and shrubs in town on this being attended to, and so much depends on the future cost of the keeping, in having arrangements made suitable for the proper performance of these duties in the first instance.

"I should also recommend that all the walks be made of asphalt, so that they may be always clean and dry for use in all weathers. Although this will entail a large expenditure at first, I believe in the end it will be better, and nearly as cheap.

"From the magnificent way in which all the other works in connection with your board (Metropolitan Board of Works), have been carried out, it will be indispensable that the finishing of this portion of the work should be in keeping with what has already been done; for, in the words of the *Builder* of January 1st, 'we must go as far south as Naples to admire, in the magnificent coast roads that fringe that unrivalled bay, a waterside drive and promenade superior to that which London will possess when the Thames Embankment is completed.'

WORK FOR THE WEEK.

KITCHEN GARDEN.

Now that winter is at hand, it is of importance to have a stock of keeping-roots in the vegetable-shed. Carrots, Parsnips, Turnips, Jerusalem Artichokes, Horseradish, Beet, Scorzonera, and Salsafy should be secured in the vegetable-shed, which ought to be several feet below the ground level, and have a close-fitting door. The above may be merely laid in heaps. If they are apt to shrivel, vegetables of this kind will be better in layers along with clean sand. Let all the *Cabbage* plants still

remaining in the seed beds be pricked-out forthwith. If there is any spare time get *Horsradish*, *Rhubarb*, and *Sea-kale* planted now instead of in the spring. In all cases be sure to trench deeply and loosen the bottom of the ground.

FRUIT GARDEN.

Let the Figs be protected immediately. Nothing is better and more simple than tying wisps of new straw successively along the stems, each overlapping the last. Let all superfluous nails be drawn from wall trees, and proceed at every opportunity with general pruning, the nailing, however, following the knife except on south walls. The trees on these had better remain until the end of January, as the buds are apt to become unseasonably excited.

FLOWER GARDEN.

Little can now be added here at present. Where lawns have not been well attended to through pressure of business, another mowing and rolling may take place. The bulk of the dead leaves should be removed immediately preparatory to a general cleaning. If the shrubs require a compost, it is a much more cleanly plan to bring back some decayed vegetable matter when a digging occurs. After so fine an autumn, during which period all bulbs have been got well into the ground, and the Tulip grower especially has commenced his labours under favourable auspices, it is advisable that every bed, however small, be properly and substantially hooped over, so that by covering with a number of Russian mats sewn together the whole length and breadth of the bed or beds, the collection may be safely defended from an excess of either rain or frost. Most amateurs were taught a severe lesson last season, the serious effects of which on their most choice bulbs will be for some time severely felt. Beds of choice Pansies ought also to be protected, and in mild weather traps should be set for snails, which even at this season of the year will cause great detriment to plants. Perhaps the best blooms of those beautiful spring flowers, the Polyanthus, can be grown in a pit, which may be built of turves from a pasture field, the roots planted in a compost of decayed leaves, loam, and sheep manure. I would advise your readers to try a turf-pit against one made with brick, at least those who are about commencing the cultivation of the Polyanthus; it will be found more secure from frost, and decidedly more congenial to the habits of the plants than growing them in pots in frames. Carnations, Picotees, and Auriculas must be kept clean and the pots not allowed to be soddened with wet; in fact, the less water the better compatible with health. The compost heap is a most important adjunct of good gardening, and in too many cases the management of it is still behind the improved practices of the present day. Such is not always the fault of the gardener, but frequently arises from an inadequate supply of labour at certain periods. I am not an advocate for complicated mixtures, still I must plead for a little loam and some other matters in the compost-yard. At this period one of the important points in this department is to see that the drenching autumn rains have every facility for escape. The best of soils, be they never so well harvested, will become soured in a very short period by the lodgment of stagnant water. A good compost-yard should on this account be a steadily inclined plane, and the soils or composts should invariably run the way of the descent in parallel ridges. Now, although the special mixing of soils a long time beforehand is by no means to be recommended, though dignified by the title of "compost," yet it so happens that in general gardening much surplus soil or vegetable matter comes to hand in the course of the year; such in all cases cannot and need not remain separate, for in the mixed state there will soon arise a demand for it, if only in renewing the beds of the flower garden. Those who have not harvested their loam should lose no time, for assuredly a little should be obtained annually if possible.

GREENHOUSE AND CONSERVATORY.

The winter-blooming *Correas*, *Epacris*, *Polygalas*, *Acacias*, *Pimeleas*, &c., will now begin to make a charming addition to the other inmates of the conservatory. Take care to give attention to judicious watering, more especially to such plants as the *Epacris*; it will not do to trust this process to inexperienced or neglectful workmen. Let all bulbs arising from their dormant state, such as the *Amaryllis* tribe, the *Lachenalia*, *Oxalises*, and others have very moderate supplies of water until the leaves are somewhat expanded. Keep down all decaying leaves, and observe the utmost cleanliness. If any of the stock appear too much crowded endeavour to weed out inferior or half-hardy things, transferring them to the pits or frames, or in case of severe need to a shed or outhouse, provided they

are of the hardy-leaved class, or decidedly deciduous. There is often occasion to employ fires at this period of the year, as much to promote an active ventilation and remove all superabundant moisture, as to make up for the deficiency of heat from external sources. However, assistance of this kind must be used with the utmost circumspection, and no actual interruption given to the system previously commenced of gradually reducing the temperature to correspond with the natural decline of the season, and consequent limitation of solar light and heat; considerable mischief cannot fail to ensue from an injudicious application of fire heat, particularly if used at night, and this should be held in view throughout the season.

STOVE.

Continue former directions in hardening growths, and endeavouring to promote a quiet somewhat dry atmosphere. Keep down all unnatural night heat. Hybrid Perpetual, Tea, and other Roses, as well as Chrysanthemums, if attended to, will render this structure, as well as the conservatory, most interesting for the next two months. Let these have weak manure water perfectly clear; it should be administered about 5° or 10° warmer than the atmosphere of the house. If given at every watering it is almost impossible to give it too weak or too clear; if the water is barely coloured it will be sufficient. An ounce of guano with a handful or two of soot will make a large bucketful or canful strong enough for anything.

FORCING PIT.

Now the leaves are falling fast it will be easy for those who have a pit at liberty to make it up for flower forcing. The leaves should have a portion of well-wrought dung mixed with them, if to spare; this will bring the leaves into perfect action immediately. About 9 inches of tan may be placed over the leaves in order to facilitate the plunging. Let the glass have a thorough cleaning. As soon as this is completed, flowers for forcing, if in proper condition, may be introduced immediately, such as the various Rhododendrons, Azaleas, Mosa or Provence Roses, Persian Lilacs, Sweet Briars, Camellias, &c., taking care at this period especially to introduce nothing unless it has gone through a proper course of culture during the summer, with the view of securing early-made and thoroughly ripened wood, for unless its condition is such it will be in vain to attempt early forcing. The Hyacinths and Narcissi potted in September may now be examined, and may be introduced successively in small quantities to the pit when their buds are 2 inches long. They should be plunged overhead at the front or darkest part of the pit, covering them 4 inches with old tan.

COLD PITS AND FRAMES.

These will now be extremely useful. Sawdust forms a good plunging material if new and dry, and coal ashes are also very good. Whatever material is employed, keep the plants within a foot of the glass unless perfectly dormant. Endeavour to keep the soil in the pot in a somewhat dry state.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

We took up the remainder of the Carrots, Beetroot, and Parsnips, and notwithstanding the dryness of the summer, we have never had better nor cleaner roots. We put a little more earth to some Celery, and would have used litter instead if we could have obtained it, but all protecting litter will be scarce this season.

Cauliflowers have a little disappointed us; the mild autumn, with the moist weather, brought it on very fine, but more quickly than we expected, so that we have hardly any worth raising in hails to plant in earth pits to be protected as we generally do. For this purpose the heads must be small, so as to grow. We have, therefore, put a good quantity in a shed, where it can be protected and will last a considerable time, though not so long as it would have done if we could have had smaller heads with good balls under glass, although the sashes were old and somewhat rickety. Fine heads of Cauliflower are easily injured. A few of ours were blackened by the frost on the mornings of the 10th and 12th, even though well protected by their own leaves, yet Geraniums in a raised border were but little injured. The very cold days at the end of the week have forced us to think of protecting and housing, or collecting in masses, to make protection easy. Were there only certain times in which certain things should be considered in season, much labour in protecting would be saved. Young Cauliflowers were saved from severe frost, and ere long we shall fill a frame with young

plants. We often find they do all the better when they grow but little all the winter, if they merely keep alive.

Kidney Beans.—We gathered about the last from an earth pit out of doors protected since the middle of October. These have done well, and clearing them out will enable us to fill the place with good plants of Lettuces and Endive, and very likely Strawberry plants in pots. Many Lettuces received a little protection where they stood, as when large the heart is easily injured. The Beans, Lettuces, &c., are a proof of what may be done late in autumn, with the help of a little protection, by *keeping the heat in the ground from freely radiating*. In this respect there is a great advantage to plants growing in the soil over other plants in similar circumstances growing in pots. To give the latter an equal chance, the pots should be plunged, and the surface mulched with dry litter. Even when rather tender plants are in pots and exposed, it is surprising what an amount of cold they will stand uninjured if the pots are laid down on the ground, and the pots and tops covered with mats or litter. This plan is the most effectual at the end of autumn and early in winter, as then the heat gained from the summer's sun has not quite radiated from the earth. Several times we have saved what otherwise would have been lost, by laying such plants down and piling snow over them when litter could not be had. The sides of exposed pots are good conductors, and soon cool the soil inside when freely exposed to the air. When sure there was not heat enough inside to cause elongation of growth, we have frequently allowed snow to lie on a cold pit for two or three weeks, as we knew it would require a very severe frost to get through it. We were laughed at once for getting a thin fall of snow swept up in a cold night, and lifted by ladder and thrown on the steep roof of a conservatory, when the boiler had given way just when its services were required. We do not recommend snow as a pleasant thing to work amongst, but it often proves one of the greatest boons to the gardener and the farmer. Many a time have we seen snow swept from pits, beds, vegetables, and plants, when it would have been true wisdom to have let well alone. We have scarcely a better non-conductor whilst it remains open and floozy.

A fine Radish bed in an earth pit we covered with some old sashes, &c., that the Radishes might be kept crisp, as those fully exposed and older, though looking well, are inclined to be hard from the cold.

Of Sea-kale and Rhubarb we took up some roots, and protected them with litter in case we should have a severe frost. We shall treat Asparagus in the same way. All these may be forced with propriety now when deemed desirable. All of them have this year ripened their buds earlier than usual. Globe Artichokes, that ripened so much earlier than usual, have now grown so green as to require more protection than if they had faded later and had grown less. Rhubarb and Sea-kale, more especially, will be the better of small mounds of ashes, burnt refuse, &c., placed over the buds as deterrents to snails, birds, and mice. The latter and rats have scooped out the buds for us where unprotected. After clearing away all litter leaves a slight sprinkling of salt between the rows will benefit the plants little, still it will keep many enemies at a distance so long as the earth remains the least saline. A few wide ridges may still be thrown up, on which to plant out young Lettuces in a fine day. If they keep alive they will feel the frost less than those succulent from growing freely.

FRUIT GARDEN.

Put the above plan in operation with our Strawberry pots, covering them slightly with litter on the afternoon of the 12th, as, even with a west wind, there were not wanting signs that we might have a severe frost. Very little protection will keep them all safe. Ere long we hope to place them under shelter. What a fine place a wide shed open to the south would be for all such purposes! There is hardly a place we know where the shed room is half enough, if the most is to be made of everything and labour economised. With Strawberry pots in beds, even out of doors, a little protection will often keep them all right, though if mice and vermin be excluded a cool place under glass is the best. We shall place a lot in frames where there is a little mild heat left, so as to bring them on gradually. They generally do best after the growth of the top has received a slight check, but with little or no check to the root action.

All fruit trees in pots not plunged or partly plunged, should be protected. Even in orchard houses the exposed parts of the pots should be protected with a little litter. When the trees are not large this is best done by setting them as closely as possible together, and then drawing the litter over and among them. By these means a large space can be cleared for winter

vegetables, salads, &c., that will require but little protection even in severe weather, when the house is dry, and the air inside still. When, however, the trees in pots are of considerable size, it is often prejudicial to lift them and pack them closely together, as thus the branches and bearing twigs are often bruised and broken. In their case, if the weather should be severe, a little litter should be put on and hang over the surface of each pot. A little artificial heat in severe weather would render all this unnecessary, but then it would not be an unheated glass case, and the inexperienced are very apt to use too much of this artificial heat in winter. In cold orchard houses such things as Parsley, Wallflowers for early blooming, early-flowering hardy annuals, &c., may be kept in a similar manner, and with but little trouble.

Chiefly to get the glass in better order, but partly to give the Figs a nipping, we have unroofed a low pit or Fig house, as after all our careful washing we still found traces of the dread mealy bug. This has enabled us to give rafters, &c., a coat of anticorrosion paint, which will shut up insects' eggs if there are any. A few degrees of frost will do the Figs no harm, and may settle all the bugs that are alive. We feel more interested, as until lately we had never been annoyed with this troublesome insect. In the hope of having a little frost first, we have forborne smearing the shoots as alluded to lately. We shall now have to look after the mealy bug everywhere, and see that he do not gain a hold. All purchasers of stove plants would act wisely by putting every new plant into a sort of hospital at first to prove it, especially as respects this insect—that is to say, if the general stock is clean. It is very unpleasant to be ever cleaning, as gardeners are obliged to be in many places, and then never be quite sure. But for the work in the Fig house, that, too, would have been filled with plants before now.

ORNAMENTAL DEPARTMENT.

For keeping a clean, smooth lawn nothing is better than a wooden roller, say 1 foot in diameter and 1 feet in length. If a little rough, it will, so far as worm heaps are concerned, dispense with all sweeping. The roller will merely be required to be scraped now and then to get rid of all the earthy matter. For small spaces, to keep down earth heaps there is nothing better than rolling, and then next day following with a good watering of clear lime water, which will thus go freely into the fresh-made holes, and kill the worms. For large lawns we must chiefly depend on the roller alone, as the watering is laborious when the lawn is large, and, besides, the worms are often good helpers to us as cultivators, even though their earth heaps give a little annoyance. By the sides of walks the heaps are often troublesome, and there lime water may be applied, as salt, though rather more effectual as respects deterring or killing the worms, would leave the part salted soft and retentive of moisture for the winter.

Considerable time has been taken up in getting the bedding plants saved in sheds, potted, and packed for the winter as previously stated. We were obliged to smoke some Cinerarias, which we rarely require to do, and we mention this all the more because the insects (green fly) came, we have no doubt, from breaking the rule so often recommended, of (after excluding frost), keeping the plants airy, cool, and moist. These plants had been placed rather close to a hot-water pipe in a pit, and as we were a little apprehensive, the pots stood on moss in a saucer. At one end of this pit there were Cucumbers, and so the pipe that went through was rather warm. The temperature where the Cinerarias were was modified by a little air left on, so as to neutralise the heat, but still the dryness was too much, and the smoking became necessary. Other plants standing cooler in another place, whence these insect-troubled ones were taken, that they might bloom sooner, were as healthy as need be. Many such circumstances open up the wide question—Whether we might not, by knowing better what plants rejoice in, keep away insects altogether, or whether we do not invite these to come by our treatment? It would appear that the juices of a healthy, luxuriant plant are less tempting to insects than the same juices when the plant is less healthy and vigorous. We have no doubt that extra heat will ever be attended with a number of insects.—R. F.

TRADE CATALOGUES RECEIVED.

P. Lawson & Son, Edinburgh, and 20, Budge Row, Cannon Street, London.—*Catalogue of Forest Trees and Shrubs.*

Stuart & Mein, Kelso.—*General Catalogue of Forest and Ornamental Trees and Shrubs, Fruit Trees, Roses, &c.*

James Dickson & Sons, Newton Nurseries, and 102, Eastgate Street, Chester.—*Catalogue of Forest Trees, Fruit Trees, and Ornamental Trees and Shrubs.*

TO CORRESPONDENTS.

* * * We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By doing so they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

N.B.—Many questions must remain unanswered until next week.

BOOKS.—A correspondent wishes for the names of books treating on Raisin, Currant, and Fig drying, and on South Australian gardening. (A. Y.).—"The Cottage Gardeners' Dictionary" will give you the information on all the subjects you name. It can be had at our office for 6s. 6d., or post free for 7s. 2d.

CROSSING WOOD.—A *Constant Reader* would be obliged if "UPWARDS AND ONWARDS" would state how and at what cost this process is effected.

LATE PEAS.—A correspondent writes that "Mr. Stephen Castle, of Prestwich, says in his letter in your last publication that to have Peas in October on this side Manchester must be very rare. Peas were gathered and eaten several times (the last time at the very end of the month), in October, at Polefield Hall, Prestwich, the residence of Mr. Howarth Ashton."

POPULARS (W. C.).—The rows of Poplars in the Regent's Park, and near Buckingham Palace, are the common Lombardy Poplar. They will be higher in time.

MASTIC L'HOMME LEFORT (W. C.).—Most of the London seedsmen who advertise in our columns could supply you.

SELECT CHRYSANTHEMUMS (H. E.).—*White*: Beverley and Mrs. George Rundle. *Rose-shades*: Prince Alfred, Christine, and Lady Harding. *Crimson and Purple*: Dr. Sharpe, Alma, and Prince Albert. *Yellow, Orange, and Brown*: Annie Sulter, Golden Beverley, Little Harry, and General Slade. The above are for specimens. *Pompons*.—*White, Golden, and Lilac* Cedo Nulli, *White* Trevanna, *Golden* Aurora, *Bob* (late), *Salomon, Durand, Andromeda, Florence, Prince Victor, and Sainte Thais*. *JAPANESE*.—The *Daimio, James Salter, Red Dragon, The Tycoon, Nagasaki Violet, Wizard, and Negro*; *Comet, Dr. Masters, Meteor, Jupiter, and Chromatella*. The last five are all shades of yellow and orange.

FLOOR OF GREENHOUSE (H. Y.).—We have no objection to the earth being the floor in your small greenhouseinery. There will be no danger of damp if you water carefully in winter. Concrete, or even gravel, and still more, tiles, would be neater; but earth is very well provided you have a pathway, and nothing is better than a narrow trellis of wood crossing in short pieces. Then when you clean the narrow trellis and rake the ground the bottom will always look neat with little trouble.

LAURELS DYING (R. O. F. S.).—We think the dryness may have something to do with your Laurels dying off one branch at a time. There are places, however, where the Laurel will not flourish many years, unless it is frequently cut down or shortened back. It is not quite so safe to cut in midwinter as early in autumn or the middle or end of March; but if work is pressing in spring we would not hesitate to cut back now, say, if the plants are large, cutting them all down from 2½ to 4 feet from the ground. The whole plant must be so treated. If a few branches or limbs are cut and the others left, the plants will most likely die at the points, and then farther back. We have frequently renewed Laurels by thus cutting-back. The cut places should be smeared over; lightish paint is best.

CUCUMBERS SCABBED (Jas. Ashby).—The rind of the fruit is affected by a dry gangrene, a result of the imperfect elaboration of the sap; but we are unable to tell whether it is caused by the roots absorbing some mineral in a soluble state that the leaves and fruit cannot appropriate, or is due to some influence of the atmosphere. All we know about it is that it is most common in limestone soil, or where the plants are supplied with water from limestone; but we have had it from using water from ironstone. It is a subject well worthy of investigation, and we should be obliged by our correspondents giving their experience.

LICHEN ON ARAUCARIA IMBRICATA (Forester).—From your description we think the green moss is a Lichen, which may be destroyed by scrubbing with a brush dipped in strong brine, so as to moisten every part of the bark affected. Equal portions of salt and water will not be too strong, but the solution must be applied to the parts where there are no green leaves, and there only. You may also dust the tree whilst wet with quicklime, which will destroy both the moss and the Lichen, but is more unsightly than brine, which leaves no trace of its application.

COVERING VINES WITH GLASS (H. Vernon).—We should prefer erecting against the wall the glass slating, or having a lean-to about 6 feet wide, and this will allow of space for a walk inside; and you could have Strawberries and Tomatoes on the front without injury to the Vines on the wall, only keep the Tomatoes low so as not to shade the Vines. At the top and bottom have a board 11 inches wide hung with hinges, which you can open or shut as needed. The moisture from the border will not be too much, and when the Grapes are ripening you can secure dryness by withholding water and giving on abundance of air. Upright sashes we do not approve of in your case, for they would be more costly and afford no greater advantages than a lean-to. Besides the Strawberries and Tomatoes you could have Vines on the roof at every 6 or 8 feet; or if you wished for Peaches and Nectarines, you might have two rows of double cordons respectively 1 and 2 feet 6 inches from the front, which in a 6 feet width of house would leave you half the width for the walk and the Vines. The glass frame ought not to be removed in the winter. It would be very useful in winter for growing salads.

VARIOUS (Centurion).—Beurre d'Arenberg would be improved by planting against a south wall, but a west aspect is best, though we have had it fine on a south wall. Cleveland Bigarreau and Werder's Early Black

Cherries succeed well on a south wall. *Rose Céline Forestier* would thrive well against the east side of your house if planted in good soil and watered well both at the root and overhead in dry weather. The varieties of *Gladiolus gandavensis* in heavy soils should be taken up now and be planted again from March to May, but so soon after the middle of March as the soil is in good condition. We know of no Apples that do well on a north wall. The *Morelle Cherry* does exceedingly well on that aspect, and so do *Currants*. We think 10 feet quite high enough for pyramid Pear trees, for when higher they are not only difficult to prune, but the fruit on the upper part is liable to be injured by wind. In exposed situations we consider bushes preferable to pyramids.

FUMES OF COKE AND CHARCOAL (*H. V.*).—They will injure all your plants, and probably destroy some.

WINTERING PLANTS IN A ROOM (*Saint George*).—We do not know of anything for keeping out frost that would serve you so well as the fire grate. You might safely have a fire all night by using a fire-guard. There is no apparatus that would suit the room and be available for a greenhouse. When you have the greenhouse we would have a small boiler, and two 4-inch hot-water pipes along the front and one end, with a stovehole outside.

GURNEY LILIES NOT FLOWERING (*A. F.*).—It is unusual for these to flower the second year, for the roots suffer considerably on being taken up. You did right to keep them growing last winter after flowering, but it was a mistake to keep them quite dry in the pots. You should have set them on pans filled with sand kept wet, even after the foliage was all gone, not, however, giving any water by the surface, but from the wet sand the pots would have derived some moisture. In August you shook out the bulbs and potted in fresh soil—that was a mistake; they ought not to have been repotted, but kept in the same pots until the bulbs had become so large as to burst them, and should have been kept on a shelf in the greenhouse constantly. We advise you to try them that way after this.

GESNERA SPLENDENS SHEDDING ITS FLOWER BUDS (*G. J. B.*).—It is apt to do so when the plants have been grown in a dry heat, and in a moister one the plants are excited into growth, and the buds drop, for the buds being formed in a drier atmosphere, they are incapable of the expansion consequent on the moist one. It is a common error to start these plants in spring and grow them all through the summer, and very often in vineries, where they are brought into a semi-ripened state just when they are forming their flowers, so that when they are placed in the stove for flowering, from the moist genial atmosphere, they start again for growth; the cause is, therefore, a check. We have known it caused by allowing the plants to become too dry, also from too much water, and from sudden changes of temperature. The only way to obviate it is to not start the plants too early. May is soon enough for winter flowering, and they should have a moist genial temperature, with abundance of light in all their stages.

POINSETTIA LOSING ITS LOWER LEAVES (*Idem*).—It is due to the wood ripening. The only way to keep on the lower leaves is to grow the plant in a good temperature, and not have any shoots but those made after June. Dwarf plants, and kept so by growing them near the glass, are less liable to lose their leaves than tall plants. The plant being deciduous, it is not possible to flower it without its losing a portion of its leaves, at least we have not seen it so flowered, except in the case of small plants.

CREeping PLANT FOR COVERING A BANK (*A Hampshire Highlander*).—We do not think you could have anything better than *Cotoneaster microphylla*; it is a neat, close-growing evergreen, producing pretty white flowers in summer, and bright red berries in autumn and winter. *Rægner's Ivy* would also answer well, having fine large leaves. *Vinca elegantissima* is also excellent. It has variegated foliage.

SELECT HERBACEOUS PHLOEXES (*B. B.*).—Comtesse de Chambord, Ange Gardien, L'Avenir, Madame Domage, Madame Barillet, Lierwali, Madame Froment, Madame Lemort, Madame La Marquise de Mironet, Madame La Comtesse de Malart, Monsieur De-lamere, Monsieur Domage, Monsieur Linden, Monsieur Marin Saison, Monsieur Veitch, Monsieur W. Bull, Queen Victoria, Roi des Rosos, Souvenir de Berryer, Vierge Marie, Annablis, Aurantiaca superba, Duc de Montebello, and Admiration.

ANEMONE-FLOWERED CHRYSANTHEMUMS (*Idem*).—Empress, Fleur de Marie, Haniel, King of Arcmones, Lady Margaret, Louis Bonamy, Marguerite d'Anjou, Marguerite de York, Miss Eyre, St. Margaret, Nancy de Sermet, and Mrs. Pethers. The training a standard *Chrysanthemum* requires is to remove all the shoots except one, or cut them away, and keep the plant to one stem until you have the height required, and then take out the point of the shoot. When it makes new shoots remove all but the three uppermost, and stop them when 6 inches long, tying down the shoots, but be careful not to break them. They should again be stopped, but not after the middle of July.

NAMES OF FRUITS (*Centurion*).—1, Much like *Passe Colmar*; 2, *Duchesse d'Angoulême*; 3, *Glou Morceau*; 4, *Consiller de la Cour*; 5, *Easter Beurre*; 6, *Belle de Noël*. (*E. Jones*).—We have no fruit from you, if with your own signature, or merely "J." attached.

POULTRY, BEE, AND PIGEON CHRONICLE.

AWARDS—TRIMMING.

WHATEVER shortcomings may fairly be urged against Mr. J. Wright, everyone will give him credit for his unvarying persistency; and though I have the well-known axiom before me as to "a man convinced against his will," I once more take up my pen in reply to his last letter. It is not difficult to reconcile his first and his second correspondence. On the 20th of October he wishes "an award of very highly commended should be given to all pens, and to those only, which in any ordinary show would be thought worthy of a place in the prize list," adding, "if, besides this, the pens highly commended were arranged in their order of merit, I think all that is necessary would be done," &c., &c.; and on November 10th he proceeds

to say, "that if I will read his remarks again I shall see that his chief suggestion was for a distinct award to be given to all pens, and to those only which in an ordinary competition, or by intrinsic merit, deserved a prize, and that this was the point on which he laid stress, and on which he wished to ask my opinion, and on this Mr. Hewitt says nothing." Evidently finding his ground as to the highly-commended pens untenable, he now leaves them out of the case altogether.

I should myself have been really much pleased if Mr. Wright had carried out his original intention, as stated on October 10th, of asking my opinion privately before mentioning it in these columns, as it would have avoided a vast amount of recapitulation and a rushing into print, contrary to my customary habits and desires. I, however, give every credit that Mr. Wright cannot possibly know the full amount of my poultry correspondence, for it is legion, and oftentimes when I have even written for twelve consecutive hours without scarcely a moment's intermission, and without desire of fee or reward—how frequently, I say, has the very next post delivery placed me in exactly the same fix in respect of poultry querists as that from which I had thus laboriously extricated myself; in fact, it is not long since our postman, when delivering my letters, said half playfully and half earnestly, "If the master's letters go on in this way I shall soon have to bring them to him in a wheelbarrow." Still, as Mr. Wright seems to have started a new transatlantic suggestion, I purpose to give the requested honest opinion as succinctly and plainly as I can do, so as to admit of no misconstruction. I cannot see much difference as to whether pens are very highly commended or simply highly commended, so long as he wishes them "arranged in their order of merit," for, if these words have a meaning at all, any practical judge will at once reply that this is not only awarding the customary three prizes, but also the additional very highly commended and the highly commended pens in "their order of merit"—a task infinitely more difficult and time-taking than the prizes themselves. If the intention of these avowed introductions is simply to give a sufficiently close idea of the state of the competition in the respective classes to would-be purchasers, surely this is as fully met by a glance at the number of pens highly commended. If they appear in numbers the competition is of necessity good, and if the prizes only are awarded, it is equally significant that the competition was at best scanty, or possibly that the prizes themselves were only reluctantly awarded by the judge to the best birds present. I repeat, from conviction, to carry out this new arrangement in the time is utterly impossible.

The American diploma Mr. Wright now substitutes for his former designation is simply placing the same facts under fresh colours. The honorary diploma card, which Mr. Wright suggests should in print state "that in an ordinary competition this pen would be worthy of a prize," will, I fear, meet with as little favour at the hands of committees as at my own, simply from the indisputable fact that poultry judges are already far too overtaxed, and cannot bear the additional feather that to a proverb destroys the powers of endurance of even the camel itself.

Not to recapitulate, I must give one other very cogent reason why increased labours in the same time are most unadvisable. If so many extra adjudications are to be made in the same time, the far more important awards for the customary prizes must of sheer necessity be proportionably hurried over and slighted, which, in my humble opinion, should never for an instant be entertained.

Mr. Wright then reverts to his old theory, "trimming," and states with "the results of his labours he is abundantly satisfied." If he is "abundantly satisfied," far be it from me to interfere with his self-complacency; but still on "trimming" he goes on to say, "Mr. Hewitt will, I think, admit there is some difference, however small, between the present time and two years ago." My admission is complete; some years back I dis-qualified, and by name published the full particulars of a very cobbling job by sticking in the tail feathers of a Bantam cock with cobbler's wax. In the present day we have, on the contrary, quite a scientific refinement on this very primitive mode of procedure: it is now the manipulation of an artist, the desired tail feathers are fixed to a nicety in the barrel of the natural quill with quick-drying varnish. The progress we have made seems to be this, as the eyes of amateurs generally are specially directed to the subject, the really exquisite workmanship of the trimmers of the present time is far more difficult to discover, and afterwards prove to conviction, than that of former days, but the intentions of those who prac-

tise these deceptions remain as unchanged as ever—viz., to obtain by fraud that which they cannot hope to accomplish by honest means.

Mr. Wright remarks, "that the worst, or one of the worst trimmers he ever knew is also a man who sells eggs that hardly ever hatch." I fancy I know several amateurs who were the victims of this individual, now happily removed from this and all other fancies. He used to sell as "eggs from his best hens" (which undoubtedly was true to the letter) eggs that, having been incubated some week or so, on inspection proved unfertilized. He sold them, gloried in his dead robbery, and gained money. In short, there are knaves in all classes of society, and, consequently, in the poultry world as among all orders; such are not poultry-fanciers, but money-getters only, and it behoves all persons to be on their own guard for their individual protection. Somewhat lately a gentleman, a stranger to myself, but who, I am informed, is a young man of very considerable means, wrote me a letter, requesting me to say whether a pen of poultry he had bought at a very long price was the first-prize pen I had before me at the — show, particularly requesting me to give him "my own candid opinion of the affair," for if, as some of his friends told him, "they were not the birds, this would be the third time he had been taken in in the same way, to his great vexation." The hamper being already dispatched, I was, as it were, compelled to see them, and to the best of my knowledge and belief I then saw them for the first time in my life. As to the requested "candid opinion of the affair," I suggested in my reply that I thought "his want of caution proved him to be plucky, but not wise." It may be urged, Why did I not conjointly prosecute? The birds were taken back and the money refunded, the seller saying "they were not the birds he now believed, but must have been exchanged in transit on the railway, and he was a great loser." Surely arbitrators have quite enough to contend with within the respective shows themselves, without being pulled into constant hot water, brought on from the want of care in confiding purchasers; and if buyers will, in direct opposition to the suggestions in my last letter, pursue the almost certain course to such difficulties, however much to be deplored, they must help themselves.

Mr. L. Wright is undoubtedly correct in his advice, "never to deal with a known trimmer;" but I must differ in opinion with that gentleman in his mode of making such an one "feel you despise him;" this cannot be attained simply by the appellations of a "reverend sinner," the "scum," &c. On minds so seared as those to whom I have just alluded, public or individual opinion goes for little; their ill-gotten gains are clutched as the result of their duplicity, and this one object attained, the expression of disgust of the victim and his friends is lost altogether, and is as ineffective where there is no moral shame to "make them feel," as would be a discharge of dust-shot levelled at the back of an alligator or a rhinoceros. Their only really vulnerable part is, in my opinion, a pecuniary one, and should I see the pen of birds alluded to again, that did win, a thorough exposure at my hands will certainly ensue, leading, I trust, to prosecution. I will not infer for a moment, as Mr. Wright appears to do, that every individual who trims is to be avoided as a man capable of even far more atrocious acts than simply trimming, and no one could regret more than I should any instance of disgrace to an exhibitor, "who is in the hands of his servant, and who knows little of his fowl himself;" but judges, of course, cannot adjudicate on the spot as to the actual aggressor, but simply on the act committed, whilst I myself really fear (and I hope not uncharitably) that in most cases of trimming, the proprietor and his man are both rowing in the same boat, pulling together, and have the self-same goal in view.

Mr. Wright asks for the publication of the name of the professor to whom, in my former letter, I alluded as caught with the cocks' combs (for there were two fowls), "sewn through and through to keep them upright;" adding he knew of one of the protestors who stained the Cochin cock's wings, but he thought it (unwittingly on my part), an injustice to refer to such an "enormity," adding "one is not some." I confess that Mr. Lewis Wright and myself differ very widely in our opinions as to the justice or even good taste of publishing an offender's name anew after he has already suffered disqualification for his crime, and consequent punishment. The birds were not disqualified by myself, but by one of the most shrewd, expert, and conscientious of our judges with whom I am acquainted. This gentleman called my attention to them particularly; at a show at which I was his colleague, held shortly

afterwards, he pointed out to me (in hand) the still unhealed punctures—for the judge himself took out the stitches at the former show—where the comb had been "sewn through and through to keep them upright." A catalogue was, after judging, produced, and, as I had been previously apprised, they belonged still to the party stated, and he was a protestor against trimming. Not for publication, as I think it uncalled-for to the offender to personally renew the charge so long time past, but to satisfy the Editors of the Journal, I enclose to them the name of the delinquent, and also that of the very reliable judge who at the time disqualified.

It being evident that Mr. Lewis Wright speaks rather from theory than from practical experience on the matter of judging poultry shows, and is, perhaps, scarcely aware of its present difficulties, irrespective of any further additional labours, I wish, therefore, to offer that gentleman a proposition that if accepted will, I think there is not any doubt, finally settle the question; and let me assure Mr. Wright that I am quite open to conviction, for if I find myself in error I hereby pledge myself to adopt his plans if they work well. We are now getting into the short days, and I have many shows at which I am engaged very shortly to officiate. Pray let me induce Mr. Wright to accept the adjudications in a single instance. I will use my best endeavour to cause some committee to acquiesce in the change. The entries shall not exceed five hundred pens, for if there are more I will cheerfully take all the excess on myself. We can arrange to begin, as promised us, by nine, and the rest of the daylight is before us; but I cannot, contrary to all precedent, promise him a bed of roses with his portion. Interruptions and distractions from the committee asking for advice, and from time to time the already completed awards for the printed catalogue, may possibly occur. But Mr. Wright shall have unrestricted liberty for the exercise to the full of all his shrewdness and practical sagacity, not only to evoke in the first instance the customary triple prizes from the original chaos of the various classes, but also unmolested he may introduce any of the American diplomas, very highly commended, highly commended ("in the order of merit"), commended, and anything further he pleases to do. When he has completed his duties, if he can still say, "I look back on the general results of my labours and am abundantly satisfied," I question whether it may not prove much after the fashion of the schoolboy when he sings—

"Multiplication is a vexation,
Division is as bad;
The rule of three does bother me,
And practice drives me mad."

—EDWARD HEWITT.

AT SOUTHAMPTON SHOW.

No. 2.

"Unto Southampton do we shift our scene."—(Shakespeare's *Henry V., Act 2.*)

TUESDAY one o'clock the Show is opened, and soon after I stand within Carlton Hall, a long building with semi-circular-headed windows on either side, and with an orchestra at the end opposite to the one at which I enter. The bareness of the walls is somewhat relieved by a portrait, bust-shaped, of some one or other of the English poets, being painted above each window, and an oil painting beneath, while the orchestra opposite me has an organ flanked by shrubs and flowers tastefully arranged. All this the eye takes in at once. On a closer look one sees a table facing one covered with the silver prizes, among which conspicuous by their beauty and value are the cups given by Mr. Merrick Hoare, M.P., and his wife. Happily for those who always win silver, there are not only cups but egg stands (how suitable!), candlesticks, a tea urn, a jewel box, spirit stands, the last intimating that the health of the Southampton Committee and the Judge were to be drunk from their contents; and I saw among the prizes that very useful thing, a biscuit tin; indeed, cups were happily not in a majority. Let other committees think of this.

The poultry pens were arranged along the walls, and on each end; and there were two rows down the body of the Hall, where also were the dear little Canaries and their kindred Finches, while Macaws, Parrots, Pheasants, and the larger cage birds, were across the further end; while the Pigeons by an excellent and very effective arrangement, had the orchestra all to themselves.

I am half inclined to fancy that the worthy Committee, by the way in which they numbered the pens, had an eye to the health of all visitors, and especially of reporters, for the numbers dodged about sublimely, and I had to walk hither and

thither, doubtless to the great benefit of my liver, but also to my great bewilderment; so if you please, let the numbers another time run in the order of the pens as they stand in the Hall, and let me also say that pens with open wire backs must be given up. The birds naturally retire back, and doing so push their tails through the wires, as I saw, to the great injury of their plumage. Then, also, if they had whole backs, the central rows could be arranged back to back. With these two exceptions, the first troubling the visitors, the last injuring exhibitors, the Show was conveniently and very tastefully arranged, and Mr. Warren, the Secretary, was, like all his brother secretaries that I have ever come across, kind and courteous. I dislike and wish to discourage unkind criticism, that criticism with a selfish motive which is too often appearing, but a hint to improve it is well to drop. "Who are the critics?" says Mr. Disraeli, in "Lothair." "Those who have failed in science and art," is the answer. Who are the severe, fault-finding, judge-censuring critics in the poultry world? Those who have failed to obtain prizes.

The Spanish class was thin, but good. The first-prize pen contained a cock with a wrinkled face and a suspicion of blindness, the hen was almost tailless (this last remark I make for the special benefit of "SNDROSHIRE RECTOR," who likes matters relating to *de-tail*), but this pen beat, of course, the next prize pen, which contained nice birds but deficient in face. The *Dorkings* (age over one year), were most numerous, but Mr. Martin's rose-combed pen won easily, the moult was on many others. *Dorking* chickens were abundant and excellent, and "commendations" were rightly sown very thick. I handled the second-prize cock, and found him grand in shoulder and back, and very promising. *Cochins* were not numerous. Out of the seventeen pens about a third were Partridge, and one only White. The Dark *Brahmas* were so few that a binocular was needed to find them, while the Light were blazing in front in long rows. The *Game* classes were good, and many were grandly-built birds, the "little bits of things" not, happily, making their appearance. The *Hamburghs* were poor save the winning birds. The *Polish* pleased me much better, and the Judges too, as every pen but one was noticed. Great credit is due to the few tenacious and spirited admirers of these birds. Messrs. Boothby and Hinton have written well on them, and have also won with their pets, though missing the first prize, which was, indeed, most excellent. Then came the *French* classes, which must, indeed, be making way, as they were very numerous. It is easy to see that the silver prizes draw. "Bother the money, I don't want it" (lucky man that!), said an exhibitor, "I want a cup."

The "Any variety" class was not numerous—seven pens only, yet the birds were very nice, witness the Black *Hamburghs* and the prize *Malays*. By the way, "Y. B. A. Z.'s" two pens of *Malays* out of the whole seven, to say nothing of the *Malay* blood that stared at me in the great frames in the Game class. The *Game Bantams* were very numerous, but mostly too Bantam-like. Where were the long legs, the thin forms, the snake heads we want? But I went back again and again to admire the cock in the cup pen; he was, indeed, a Game bird. It was gratifying to see a revival in *Sebrights*, they numbered ten pens, far more than Birmingham could show a few years ago. Of *Ducks*, I must say some were "little ducks;" indeed, those called *Paradise* might have been petted by Eve herself. *Geese* and *Turkeys* apparently stayed at home all but a few.

The "Selling class," that class useful in enlarging the poultry fancy, was numerous, and the prices sensible; the *Pheasants* very beautiful, but very few. I must notice a pair of *African Cranes*, who craned their necks, apparently thinking, "Where in the world have we got to?" The dead poultry and eggs were not ornamental, but certainly in the interest of utility, and should, therefore, always appear at a poultry show.

Mounting the platform-like orchestra I find the *Pigeons*, and here the numbers were so puzzlingly placed that I had to play a game of hide-and-seek to find them. Strange that so few *Pouters* were shown, when *Fantails* numbered so strongly. Is the grand old fancy bird not loved as formerly? As at Glasgow, Bines won, and, except one pen, all were good. Good, too, very good, were the *Tumblers*. Among the *Barbs* all the winners were Blacks. The *Jacobins*, first prize, were very rich in colour, and excellent. The *Fantails* were marked "a very excellent class." Among the *Owls* nothing could exceed the first-prize birds, they were fairy-like; the highly commended birds, white with blue tails, much pleased me. *Turbits* very good. *Carriers* few, and the few pens not full, but good in quality. Among the *Trumpeters* there were a grand pair of

Blacks for first prize. The *Dragoons* produced a novelty, for a pair of *Yellows* were first, beating *Blues*. The "Any distinct variety" class pleased me greatly, and the *Black Florantines*, together with the *Leghorn fowls* and *Paradise Ducks*, were the new things of the Show. Among the "Selling class" were some good birds, and not dear. In short, a better number of fancy *Pigeons*, more advantageously exhibited, it has seldom been my lot to see.

And now descending the orchestra, I go to inspect the *Canaries*, which, to say truth, drew my heart to Southampton. It seems to me that fowls endure a show, and in the evening get excited; that *Pigeons* dislike a show; but that those dear little bits of caged vanity *Canaries* delight in a show, quite revel and glory in it, and think it such an excellent opportunity for getting admiration. How they like the company; how, if healthy, they strut and hop and twitter; how they pop their heads through the hole in front, not by any means always to get water, but to get nearer to you, and to show off their little heads; how each tiny bit of feathered conceit seems to say, "Come now, am I not the very prettiest of all? Say so, there's a good chap." The *Clear Norwich* stood, as they always ought, being *par excellence* the *Canaries*, first and foremost, and more thorough *Jonques* (I prefer that term to *Yellows*), it was impossible to imagine, as may be inferred from eleven being noticed out of twenty. Oh! Why would the breeders make a poor country parson break the tenth commandment? *Clear Buff* (no, I won't have it); *Clear Mealy* followed, and such "intensifying the colour under the meal," as says our "W. A. B.," I never saw exceeded. *Mealy!* why, sir, they were, some of them *Jonques* frosted on the back. *Cleaver* cleft his competitor in twain, and secured second prize. *Marked and Variegated Jonque* and *Mealy* were also good. The *Any variety Norwich* were chiefly *Crested* birds, some of great beauty, the dark full crest in many being as good as possible. Then the *Belgians*, those to my poor untutored mind elongated bits of distortion; but, please, no challenge from your admirers, for I should claim "liberty of clergy." Kindred to *Belgians* clearly are *Scotch Dons*, a few of which appeared; they are *Belgians* sent to a posture-master, and taught to put down their shoulders. Then came the *Lizards*, and I felt What a pity it is that your great and singular beauty does not last more than one season. The first-prize bird was fairly good, and the *Silver-spangled* were also very excellent, all noticed but one. But, perhaps, the gems of gems were the *Goldfinch Mules*. I could not leave them. Think of all being so good as to be noticed. No wonder, when such a perfection of colour, markings, and shape, are possible of attainment that *Mule* breeders, in spite of a hundred disappointments, should still persevere. Here was a *Jonque*, pure in colour, with a *Goldfinch* glow on the head, and even wings. Then the *Mealy* first-prize was cream of the cream, a suitable description for so light a bird. Perhaps this bird was the best of all, and the fine *Goldfinch* beak in place of the shorter *Canary* beak gives a delicate point to the slender shape of *Goldfinch Mules*, and sets off their symmetry. "Any other variety" class produced some singular *Mules* as to breeding, and a first-prize *London Fancy*. I own I was perfectly fascinated by the Southampton *Canary Show*, which exceeded all even that I had heard of it.

The *British Birds* gave variety to the scene, though one pitted the *Larks*, and said to the *Nightingale*, "You bird of the night are indeed out of place here." Then the *Foreign Birds* gave colour to the scene. First-prize *Cockatoo* got off his prize ticket and trampled it under his foot—his estimate of honour! The *Macaes* and *Cardinals* gave a tropical glow to the Show; while *Whidah Finches*, old favourites of mine, whisked their long tails or moved slowly like *Court Ladies*.

Such was Southampton Show, something worth writing about; and why, I ask, should there not be cage birds at all covered shows? An ornithological exhibition must bring more visitors, and be in itself more beautiful than merely a poultry and Pigeon show. Embrace all varieties of birds, and you cater for all varieties of tastes. The man who loves a Game cock despises a *Canary*, but the lady who loves the latter thinks the former a horrible bird. Please them both; do another year at Bristol as is done at Southampton, and then *Clifton Ladies* will send their pets, and many more come into the Drill Hall.—WILTSHIRE RECTOR.

NON-PAYMENT OF PRIZES.

At the Great Horton Show held September 10th, a prize list of which appeared in your columns, we obtained second prize

in Class 13, and having repeatedly applied to the Secretary for the same without meeting with any response, we beg to ask you what steps we should take to obtain payment?—W. & C. BURNISTON.

[Let your solicitor give notice that if the prize is not paid proceedings will be taken in the County Court.—Eds.]

SOUTHAMPTON SHOW.

I PURCHASED a pen of prize poultry at the late Southampton Show, gave my name and address at the Secretary's office, and paid for it by cheque. I was assured that the birds would be sent to me by rail as soon as the exhibition closed. Five days elapsed, and after in vain sending every day, at considerable inconvenience, to the railway station, I wrote to Mr. Philip Warren, the Secretary, demanding the reason for the delay in sending them, but received no reply. I also wrote to my banker, requesting him not to honour my cheque, but found it had been presented and cashed three days previously. I then thought of writing to the exhibitor, and by return of post had a very kind answer, stating that he was not aware the birds had been claimed, as they were sent back to him, and it was fortunate I had written in time, for he was on the point of selling them to another person.

I would on no account charge the Secretary with dishonourable conduct, but I do most unhesitatingly accuse him of gross carelessness and neglect of duty. I am perfectly aware that the secretary of such exhibitions has a most arduous task to perform, and allowances must be made for accidents; but when a man undertakes a duty of the kind, he should feel his responsibilities to the public, and, instead of sending a clerk to the office, endeavour to be there himself.—J. D. HOYSTER, *The Parsonage, Bradenstoke, Chippenham, Wilts.*

P.S.—I have just received (November 12th) the enclosed note from Mr. Philip Warren. Nine days after the Show he has thought proper to reply to my letter.

AYR ORNITHOLOGICAL SOCIETY'S SHOW.

(From a Correspondent.)

THE ninth annual exhibition of this Society was held in the Assembly Rooms, Ayr, on the 12th inst. The Johnstone Show being unfortunately fixed for the same day, there were considerably fewer fancy Pigeons than in former years, but the young Pouter and Fantail classes were the only two which were deficient in quality. The former of these was a complete failure, there having been only three pens on view, none of which in former years would have been considered worthy of mention, the first prize being awarded to a pair of Meales of more than average length, but unmatched for colour and markings, and deficient in carriage, although the absence of blocks in the pens somewhat accounted for the lack of motion. The other two pens, Black and Red, were better in colour and markings, but much inferior in length of feather and form. The Pouters in the class for any age belonged to a much superior grade of birds, and although few in numbers (seven pairs), there were several first class pens. The first-prize Red cock, originally from the loft of Mr. John R. Adam, of Canning Park, is an old winner at this Show, and well deserved his place, although the hen, never his equal, was in bad feather. The second-prize pen (Black) consisted of well-matched fair birds, but I think they would have been better placed after the pen of Whites, which were placed third; but all the others mentioned were so good and level in quality, that I was not surprised to hear many fanciers of different opinions as to the places awarded.

The first-prize Carriers were a magnificent pair of Duns, which judges and the public alike at first sight challenged as both cocks, but they proved their sex, and were universally admitted to be deserving of their place. The second-prize birds in my estimation were much inferior to the very highly commended pen, and the third to several not placed at all.

The Short-faced Tumblers embraced six pens, all of superior quality; amongst them were several English celebrities, and I should have liked to have seen pen 19, a pen of magnificent Blue Beards (hitherto known as Mr. Frank Graham's, if I mistake not), placed higher than very highly commended, but the three prize pens were all splendid Almonds; the first two matched to a feather, and the third, containing an old cock of extraordinary merit in head, beak, and carriage, but too dark, and matched to a hen of comparatively little value. Altogether, however, this class was an honour to the exhibition.

The Barbs filled only four pens, and I rather think that the judges made a mistake in not placing the third first, and *vice versa*, as in everything except bright cere I thought them inferior to all the others exhibited, and, before the Show closed, the cere was considerably faded. I noticed that the very highly commended pen consisted of birds of 1870, and I should have liked to have seen them awarded a prize, as they were of rare quality.

The Fantails, as I have stated, were a sorry lot, for although a few

good birds were shown, there was not a pair of even average merit. The first-prize cock was a grand-tailed bird, but devoid of nerve, and the hen was in my estimation simply a weed. Had the hen in the very next pen belonging to the same exhibitor been shown with the first-prize cock, the pair might have been worthy of a first place, but amongst so many inferior birds the judges could not, perhaps, do better than they did.

The Jacobins, however, were the feature of the Exhibition, the whole class being magnificent in chain and hood, and I believe the judges must have decided the merits of the birds from the single point of size, if I except the second-prize Whites, which for Whites were really good. I think, however, that the first-prize Blacks should have given place to the third-prize Yellows, and the very highly commended Reds, both of the same owner, a very young lady, who is to be envied for her magnificent stud of little short-faced, heavy-hooded, and long-chained Jacks. The Trumpeters were no fewer than I expected in a place celebrated for this breed, and it is not too much to say that the first-prize Blacks cannot be equalled out of Ireland. The Turbits, as a whole, were good, the first-prize Reds and the second-prize Blues being first-rate. In Owls I never saw such close competition—so close, indeed, that fanciers wondered how the judges managed to draw a line, there being only one pen below exhibition merit. Nuns and Magpies were shown together. The former (all coarse except the first-prize pen), monopolised the prize cards; but the Magpies, I think, were far more deserving. The common Tumblers and Selling Class call for no remark, but the three pens placed in "the varieties," were all splendid specimens, and there were many others of great beauty and merit.

The *Canaries* (all of the Scotch Fancy) were admitted to be superior to any ever seen in Ayr, although the local exhibitors did not succeed in keeping many prizes at home. There was a good show of fancy Doves, and conspicuous upon the tablea was a beautiful pure white Robin, the property of Sir Peter Coates, one of the Patrons of the Society, or rather of Miss Coates, which attracted much notice.

Annexed is the prize list.

POUTERS.—*Young*.—1, A. C. Glass, Ayr. 2, D. Munn, Kilmarnock. 3, A. Crawford, Both. *Any age*.—1, J. Mair, Kilmarnock. 2, D. Munn. 3, G. B. Phillips, Ayr. *hc*, Miss E. M. Beveridge, Ayr. *c*, A. H. Imrie, Bourtree Park, Ayr.

CARRIERS.—1, A. Brown, Kilmarnock (Dun). 2, D. Munn (Black). 3, Miss E. M. Beveridge (Black). *hc*, R. Gibson, Kilmarnock. *hc*, J. Mair. *c*, A. C. Glass.

TUMBLERS (Short-faced).—1, T. Wilson, Gas Works, Stewarton (Almonds). 2, J. Mair (Almonds). 3, Miss E. M. Beveridge (Almonds). *hc* and *hc*, Miss Beveridge (Blue Beards and Azates).

BARBS.—1, J. G. Orr, Both (Red). 2, D. Young, Ayr (Black). 3, Miss E. M. Beveridge (Red). *hc*, G. B. Phillips (Black).

FANTAILS.—1, R. McM. Banks, Bromberry (White). 2, T. Wilson (White). 3, R. Gibson (White). *hc*, F. Graham, Birkenhead. *hc*, J. D. Birrell, St. Q. *c*, J. Galt, Kilmarnock.

JACOBS.—1 and 3, Miss E. M. Beveridge (Black and Yellow). 2, J. Galt (White). *hc*, Miss Beveridge (Red). *c*, D. Young (Red).

TRUMPETERS.—1, Miss E. M. Beveridge (Black). 2, D. Munn (White). 3, Miss Beveridge (Mottles). *hc*, J. G. Orr (Mottles). *hc*, G. B. Phillips (White). *c*, J. D. Birrell (White).

TURBIS.—1, Miss E. M. Beveridge (Red). 2, D. Munn (Blue). 3, Mrs. J. Mair, Babry (Silver). *hc*, D. Young (Red). *hc*, R. McM. Banks (Silver). *c*, W. McKinlay, Kilmarnock (Blue).

OWLS.—1, A. H. Imrie (Blue). 2, W. McKinlay (Blue). 3, J. Mair (Blue). *hc*, Miss E. M. Beveridge (Blue). *hc* and *c*, G. B. Phillips (Silver).

NUNS OR MAGPIES.—1, F. Graham (Black Nuns). 2 and *c*, W. McKinlay (Black Nuns and Magpies). 3, T. Imrie, Bourtree Park (Black Nuns). *hc*, G. B. Phillips (Yellow Magpies).

TUMBLERS (Common).—1, G. B. Phillips (Black Balds). 2, W. McKinlay (Blue Beard). 3, A. C. Glass (Yellow). *hc*, R. Kirkland (Black). *hc*, Miss E. M. Beveridge (Mottles). *c*, A. Crawford (Black).

ANY OTHER VARIETY.—1, T. Imrie (Archangel). 2, Miss E. M. Beveridge (Starlings). 3, F. Graham (Lahores). *hc*, J. McCreath, Forehill (Dragoons). *hc*, A. H. Imrie (Antwerps). *c*, G. B. Phillips (Austrian Pouters).

SELLING CLASS.—1 and 3, G. B. Phillips (Pouters and Carriers). 2, T. Imrie (Blue Pouters). *hc* and *c*, A. Crawford (Fantails and White Barbs). *hc*, R. McM. Banks (Priests).

CANARIES.

YELLOW.—*Cock*.—1, R. Hanston, Kilmarnock. 2, D. Dick, Kilmarnock. 3, J. Pattison, Elderslie. *Hen*.—1, J. Wilson, Both. 2, R. Crawford. 3, R. Crane, Dalmeington.

BLUE.—*Cock*.—1, J. Conn, Arnieck Lodge. 2, R. Crawford, Kilmarnock. 3, T. McVie, Kilwinning. *Hen*.—1, H. Davidson, Arnieck Lodge. 2, R. Houston, Kilmarnock. 3, R. Crawford.

PEARLS.—*Yellow*.—*Cock*.—1, H. Johnstone, Johnstone. 2, J. Glasgow, Both. 3, H. Calder, Ayr. *Hen*.—1, A. Crawford. 2, J. Sealuar, Kilmarnock. 3, H. Johnstone. *Buff*.—*Cock*.—1 and 3, A. Foreland, Galston. 2, J. Norris, Ardrossan. *Hen*.—1, A. Crawford. 2, E. Baxter, Both. 3, J. Norris.

GOLDEN-NECK.—*Yellow*.—1 and 2, G. Bryden, Ayr. 3, J. M. Nicol, Pottery, Old Cumnock. *Buff*.—1 and 2, H. Goudie. 3, J. M. Nicol.

PARROTS.—1, R. J. Newton. 2, A. Glass. *Shell*.—1, R. Smith, Ayr.

STOCKTON-ON-TEES ORNITHOLOGICAL SOCIETY'S SHOW.

THE second annual exhibition of Canaries, Moles, and British birds, was held in the Temperance Hall, Stockton, on the 12th inst., when birds of first-rate quality were brought together, but the number was somewhat smaller than last year.

The closest competition was in the Lizard classes, which were remarkably good, the same birds being exhibited as those sent to other shows in the district, although some of them have since changed owners. The Norwich classes were also very well represented. The Variegated Male prize bird was a splendid yellow. The British birds made up the most extensive class in the Show, and embraced a great variety of specimens, some of which, although they did not boast a card on the cage, were very much admired by visitors.

Subjoined are the awards.

BELGIAN.—*Clear Yellow*.—1, J. N. Harrison, Belper. 2, R. Robinson, Middles-

brough. *hc*, R. Corney, Stockton. *Clear Buff*.—1, J. Jackson, Stanhope. 2, R. Robinson. *hc*, J. N. Harrison.

NORWICH.—*Clear Jonque*.—1 and 2, Moore & Wynne, Northampton. *hc*, T. Irons, Darlington. *Clear Buff*.—1 and 2, Moore & Wynne. *hc*, R. Simpson, Whitby. *Evenly-marked Jonque*.—1, R. Hawman, Middlesbrough. 2, Moore & Wynne. *hc*, C. Greenwood, Scarborough. *Evenly-marked Buff*.—1 and 2, Moore & Wynne. *hc*, W. & C. Burniston, Middlesbrough. *Ticked or Unevenly-marked Buff*.—1 and 2, Moore & Wynne. *hc*, R. Hawman. *Crest*.—1, T. Irons. 2, R. Hawman. *hc*, Moore & Wynne.

COPY CREST.—1, Fairclough & Howe, Middlesbrough. 2, W. Cotton, Middlesbrough.

LIZARD.—*Golden-spangled*.—1, R. Hawman. 2, Stevens & Burton, Middlesbrough. *hc*, R. Ritchie, Darlington. *Silver-spangled*.—1 and *hc*, Stephens & Barton. 2, R. Ritchie.

CINNAMON.—*Jonque*.—1, Fryer & McClune, Stockton. 2 and *hc*, T. Irons. *Buff*.—1, T. Irons. 2, Moore & Wynne.

YORKSHIRE.—*Clear Yellow*.—1, J. Rowland, Skelton. 2, H. Ward, Skelton. *Clear Buff*.—1, W. W. Johnson, Northallerton. 2, J. Jackson, Stanhope. *hc*, H. Ward. *Variiegated Yellow*.—1 and 2, Stephens & Burton. *hc*, A. Webster, jun., Kirkstall, Leeds. *Variiegated Buff*.—1, R. Hawman. 2 and *hc*, Stephens & Burton.

CANARY.—*Clear Green*.—1, Stephens & Burton. 2, H. Jordison, Stockton. *hc*, Tenniswood & Brown, North Aclam, Middlesbrough. *Any other Variety*.—1, T. Craigis, Darlington. 2, Moore & Wynne. *Collection of Six, in variety*.—1, Stephens & Burton. 2, R. Layfield, Darlington. *hc*, T. Culvert.

GOLDFINCH.—*Variiegated*.—1, H. Ashton, Prestwich. 2, W. J. Stewart, Darlington. *hc*, W. & H. Winter, Guisborough. *Dark*.—1, Stephens & Burton. 2, W. & H. Winter. *hc*, M. Jackson.

GOLDFINCH.—1, J. N. Harrison. 2, Stephens & Burton. *hc*, Tenniswood and Brown.

LINNET (Brown, moulted).—1, W. & C. Barniston. 2, J. N. Harrison. *hc*, Fairclough & Howe.

BRITISH BIRD (Any other variety).—1, Fryer & McClune. 2, R. Corney, Stockton. *hc*, G. Deighton, Darlington.

SPECIAL CLASS (Brown Linnet Mule).—1, C. Robison, Gainford. 2, W. & C. Barniston. *hc*, R. Hall, Stockton.

JUDGE.—Mr. John Blenkinsop, Darlington.

HATFIELD ORNITHOLOGICAL SOCIETY'S SHOW.

"We had only seven classes last year. Arthur and I got it up. But you see we have done better this year." Verily, Hatfield is a fit illustration of the oft-repeated truism, "Unity is strength." At some places one sometimes finds a want of unanimity, and we hear of splits in the camp. All don't pull the same end of the rope. Such might take a lesson from the Hatfield "Happy Family." Only seven classes last year, but this year twenty-two, with an entry of more than two hundred birds! I think that is doing better; and better will be made better still another year, for a more enthusiastic, energetic set of workers it would be hard to find. "Arthur" is not Secretary, nor was my informant; indeed, it would be difficult to define the relative positions of the various members of the executive, all were so earnest and hearty. Mr. George Stones, the Honorary Secretary, it was evident, was the mainspring of the clock, but the timepiece seemed made of such a happy combination of material, that undue expansion or contraction of parts is next to an impossibility.

"Arthur" met me at the railway station with a dog-cart and fast-stepping horse—that is, when it began to step after the manner of horses generally, for its first performance was on its hind legs. I was afraid it might feel inclined to stand on its other legs, and a thick kicking-strap appeared to me very much like evidence that it would rather like the fun. However, after a few capers, backing, and filling, and trying to go astern, the three-year-old condescended to go on, and soon whisked us into the historical village of Hatfield; not so quickly but that "Arthur" had time to tell me with evident pride that as recently as May last the horse was unbroken, and no one but himself dared open the stable-door. And my life is not insured!

I was so much engaged all day that I had no time to explore the beauties of the place, and contenting myself with the information that a battle was fought in 688 (I won't answer for the date), at Hatfield Rings, that some of the armour dug up on the field of battle is in the grand old church of St. Lawrence; and that in the vestry of the same church there is a Peter's pen-box, of which there are only three in England. Contenting myself with this, I resolved to fall back on the county directory, which, unfortunately, tells me nothing. *Ex nihil, nihil fit* will apply. I did make a few pencil memoranda on the back of my catalogue, but they're all rubbed out, and I can't help it. I can just make out something about the end of Westfield House being covered with beautiful variegated ivy, and that's all.

The Show was held in the Boys' School, an old brick building bearing date 16-something, erected and endowed with a small annual income by some benevolent old gentleman of the period. The room was very tastefully decorated with festoons and wreaths of evergreens, interspersed with delicious autumn flowers, while several very cleverly executed scrolls with appropriate mottoes were traced on the broad whitewashed beams of the ceiling, from which, too, were suspended some vegetable marrows and pumpkins. It was evident that Hatfield meant to

do the thing properly. The whole village—village! it's more like a town, has a market, and is lighted with gas—was laid under contribution for wherewith to cover the walls; and the cases of stuffed animals and birds so obtained were in themselves a most interesting exhibition, and sufficient to stock a decent museum. From the collection I should infer that Hatfield is very prolific in weasels, stoats, polecats, and other scented Digitigrada; that they are found singly, in pairs, and in groups of six, and that they feed on every conceivable form of animal whose blood consists of red sealing-wax; that many varieties of Owls, Hawks, and other Accipitres are indigenous to the neighbourhood; while the Passerine, Scansores, Gallinaceæ, and Grallatorieæ have numerous representatives. Frosty weather, too, sometimes brings visitors from the Palmipedes, and a fat little specimen in a neat glass case was pointed out as having been won as a prize at a bird show at Doncaster. One bird puzzled me sorely. In shape it resembled nothing which ever issued from an egg. Such a Mule would make any man's fortune. A friend with whom I had much pleasant chat during the day, said it was a hen harrier, but I think it should go in the "Any variety" class.

I must not forget the pigs—pigs at a Canary Show? Yes. Why not? Outside of course. Proud the owners were of them, and well they might be, as they lay snugly ensconced in mountains of clean straw, themselves hillocks of fat. I thought them a very useful kind of bird to a cottager on 14s. a-week.

The Show proper was a great success. All the staging was draped à la Crystal Palace and Sunderland, and very pleasing was the general effect. From the prize list underneath the character of the birds will be easily gleaned. Mr. Young appeared for the first time this season, his hitherto matchless Buff Variiegated Goldfinch being much admired. No. 121 in the same class, bred and shown by Mr. W. Chesney, was a remarkably nice Jonque bird. It is of the heavily but evenly-marked class, grand in colour and in splendid condition, but not very large; a bird very bad to beat in anything but first-class company. There was quite a show of Goldfinches and Linnets, about fifty in all. The district abounds in them.

The Show was well attended throughout the day, in fact the room was crowded with ladies and gentlemen in the evening, and moving about was a difficulty. It closed at nine, and then began the packing for Stockton, and well it was done. "Arthur" had conveyances in attendance to run the Stockton lots to Doncaster, and he and I did the journey behind the three-year-old, who repeated his morning waltz with a few new steps. What a glorious drive! a good road, a good nag, a moonlight night, and a beautiful country. Left Doncaster 1.20 A.M., and reached home 6 A.M., half frozen.—W. A. BLAKSTON.

JUDGE.—Mr. W. A. Blakston, Sunderland.

NORTHAMPTON CANARY SHOW.

If ever a Canary Show merited the support of the fancy, surely that under the management of Mr. G. Moore at Northampton is, of all others, that show. I notice that the entries close on the 19th, that is on Saturday next, and Mr. Moore ought to receive such a bumper as is not often accorded to any Secretary. Moore and Wynne, the Siamese twins, a kind of double-yolk arrangement, are, I think, the greatest supporters of our Canary shows in England, while the town of North-

ampton generally contains more all-England exhibitors than any other place. No catalogue is complete without them, and seldom, indeed, does one appear without their names figuring prominently in the front, and dull would our stages appear unless lighted up by the wonderful birds they send out. I do hope that this short reminder may attract the attention of many an exhibiting committeeman, who has often been cheered by Moore and Wynne's bulky envelope on the eventful day of closing of entries; and that in east, west, north, and south, in every place which Northampton has for years generously patronised, it will be considered a fitting opportunity to pay a graceful compliment to the town by sending entries to *its* Show.—W. A. BLAKSTON.

"WAR ON THE BRAHMAS."

At a meeting of the North-western Poultry Association, held at Chicago some time since, there was a very lively discussion on the standard of excellence of Light Brahma fowls, whether they should possess a single or double comb. Many of the members of the Association expressed themselves dissatisfied with the standard of excellence of the Brahma fowl, now recognised by many breeders.

Daniel Worthington, President of the Association, presented various authorities, showing the original Brahmas to have been quite different, in style and shape, from the present standard; stating they were generally single-combed, the pea comb being the exception; that the form was more round and plump; shorter legs and bodies; not so gawky, and better layers; colour, slightly buff on the back, with a general mixture of grey.

After discussion *pro* and *con*, it was finally decided that as the present Light Brahma fowl was certainly a very superior bird, and the standard now in use was endorsed by all the prominent American and English breeders, the Association would not change the present standard, but rather adopt another for the Light Brahma, with *single* comb and markings in conformity to the authorities quoted by Mr. Worthington, thus enabling exhibitors to show both single and pea-combed fowls.

A late number of the *Prairie Farmer* remarks upon this subject (the war on the Brahmas), as follows:—"It is at last over, and there is peace in the hearts of the combatants. The question of double combs and single combs for Brahmas, is settled in a manner that ought to please both sides, whether it does or not. The decision virtually amounts to this:—That a Brahma fowl may possess either a single comb or a pea comb, according to the taste of the individual breeder; at least such is the decision of the North-western Poultry Association. The protracted discussion among its members has resulted in making two classes of Light Brahmae, and in establishing a standard of excellence for each."

This Society, in its proceedings, ignored the standard of excellence and description of this breed of fowls, as laid down by Tegetmeier, as being "incorrect and not adapted as a safe guide for the judging of" Light Brahma fowls. Whether the action of this Society in this particular will be adopted by others yet remains to be seen.—(*Moore's Rural New Yorker*)

THE YORK RABBIT SHOW.

MR. MILLINGTON takes me to task for commenting on the glowing account given by "CUNICULUS" of the attractive prize list for Rabbits at the approaching York Show, and declares the schedule to be "the very best ever issued by any committee in England." I have not the courage to deny such a positive statement; but as few things under heaven are absolutely perfect, I would ask, Where is the justice of charging the same entrance fee for the Variety classes as for the Lop-ears, and then awarding less prize money? This outrage on common fairness is the more apparent when it is remembered that Rabbits for the Variety classes must (I know not why) be in pairs, entailing more expense in carriage. If the York Committee think this just, I believe the fancy generally will wonder where they learnt logic. Surely the same proportion of entrance fee to prizes ought to be maintained in all classes of Rabbits, unless the Committee wish systematically to discourage the exhibitors in the Variety classes, who, however, cannot easily be dispensed with. The latter cannot see why they must send their specimens in pairs more than the Lop-ear fanciers; but Mr. Millington emphatically says, "I differ from your correspondent; I think they ought to be shown in pairs." but he does not vouchsafe one reason to show the reasonable-

ness of his dictum. Mr. Millington quotes the last Hull Show as proving my inconsistency in thinking a cup might have been given at York for the Varieties, when two cups are to be offered for Lop-ears. I would remind him that ours at Hull was a newly-started Show, and that the Committee had to tread their way very cautiously, which is not the case at York, where there is annually a large surplus. At all events, we did act justly and consistently in our money premiums, giving to Lop-ears £1 and 10s. prizes, entrance fee 2s. 6d.; and for varieties 15s. and 7s. 6d., entrance fee 1s. 6d. This proportioning of the fee to the premium is, I think, an arrangement that must commend itself to all lovers of fair play. It was not I, but another correspondent, animadverting on the injustice of the York schedule, who spoke of pairs being put into one pen, and often presenting disgusting scenes. I, who know how the arrangements are at York, cheerfully admit that in this respect the Show is a model for others; but nobody knows better than Mr. Millington that in nineteen cases out of twenty the Varieties are put in pairs into pens, and that no exhibitor can be certain what state his doe may be in when she comes home.—L. G. HUBSON.

EXPERIMENTS WITH PERMANGANATE OF POTASH AS A CURE FOR FOUL BROOD.

NOTWITHSTANDING the many investigations which have been made, and the different opinions which have been expressed, by men eminent in the apian world of science, the origin and cause of this fatal disease have hitherto baffled all attempts which have been made to discover them, while its cure remains equally shrouded in mystery. Like many other bee-masters, I have suffered very considerably from this plague, hence I am naturally anxious to find out a cure, and ever ready to make any experiments in which there is the smallest possible prospect of success.

A friend of mine received from an English apian a small quantity of the permanganate of potash, with instructions for using it as a cure for foul brood, but he having no diseased colonies sent it to me, and I happening at the time to have a colony affected with this dreadful malady, readily agreed to give it a trial. The following is the mode of proceeding:—The quantity sent (as much as would lie on the point of a table-knife), should be dissolved in a gill of water, of which solution a table-spoonful will be sufficient for each pint of syrup, to be given to the bees whilst in quarantine. As soon as they have all partaken of it, which they will readily do, mix a little essence of peppermint with some of it, and pour it on them in the skep in which they have clustered, so as to insure their being wetted with it, rolling them actually in it, and then they may be turned into a healthy stock or amongst healthy combs. He adds, "It is a simple remedy, but has effectually cured foul brood in two stocks of mine. As far as I can judge, it is only necessary to wet the bees inside and out and the cure is complete." He likewise says, "If the foul bees are driven from a straw skep, they will, of course, require more time than if simply brushed off the combs, as they will have filled their honey sacs with diseased honey; but I do not think they will require more than twenty-four hours, unless the swarm is large."

Having diluted this disinfectant as described, I took the required quantity, mixed it with a pint of syrup, and placed it upon the top of the hive (the bees having been previously transferred to an empty live), but they did not partake of it very willingly, for although I allowed it to remain for two days, they had not wholly consumed it. I now turned my attention to the second part of the prescription, took a quantity more of the solution, adding to it a small quantity of the essence of peppermint, turned the hive upside down, and poured it gently upon them. But, oh, what a calamity! the cure was worse than the disease, as in less time than it takes to write it, the little creatures had wholly forsaken the hive, with the exception of a few who were so wet as to be unable to fly. Never did a despotic monarch abdicate a throne, nor the inhabitants of a plague-stricken city flee, with greater haste than did this royal lady accompanied by her loyal and industrious subjects. I was so paralysed by this unexpected event that it took me some little time to comprehend it; but on recovering from my bewilderment I found my bees clustering on the landing-board of another hive, the inmates of which had set a strong guard lest these panic-stricken emigrants should attempt to find a lodgement in their midst. But where was my queen? After a considerable time spent in fruitless search, I found her lady-

ship with a few attendants on the branch of a currant bush close by. Having secured her, I placed her at the entrance of her home, expecting her to enter, but this she positively declined to do, and again fled; a second and a third time I tried her, but she as often refused, and it was only after I placed a clean hive on the stand that she consented to enter, taking along with her her loyal subjects.

This, then, is a brief account of my latest experiment with a foul-broody stock, and, like many more would-be cures, has entirely failed, as the colony still remains diseased; and as I know of nothing better, nor so effectual, I give my adhesion to the plan known as the purgatorial process.

Immediately on discovering that a colony is affected with foul brood, remove the bees from the infected hive to an empty one, allow them to remain there for a few days in order that they may thoroughly clean themselves, when they may be transferred to their permanent abode. This method I have tried with considerable success.—A STEWARTON APRIANIAN.

THE LONDON POULTRY SHOW.—We are very glad to learn that the entries for this Show have proved so numerous; they amount to nearly 1250 pens of poultry, and about 800 pens of Pigeons. Never before were so many Pigeons entered at one show. The Pouters alone muster 220 pens.

OUR LETTER BOX.

INACTIVE CROP (*Subscriber to the C. G.*).—Your fowls are suffering from stoppage between the crop and gizzard. You must discontinue feeding till you have opened the passage, then give small quantities of water as hot as can be drunk by the birds without injury. Follow up with doses of castor oil till the functions of the body are freely discharged. You must then feed on soft food, as sopped bread, for three days. (*C. J. S.*)—Your case is not an uncommon one. At this time of year the fowls pick up hard and dry grass that will not digest. It causes discomfort, which they try to relieve by drinking. There is a stoppage between the crop and the gizzard. There will be no cure till it is removed. We have given full instructions in a previous answer.

VULTURE-HOOKED BRAHMAS AND COCHRINS (*Mrs. C.*).—Vulture hooks should be eschewed in all breeding stock, as they amount to disqualification. The fault will sometimes appear in the progeny, but in fowls, as in everything else, the perfect birds form the exception, and to have many of them it is necessary to breed well, and kill well. By this process you will get rid of the vulture hook.

FROTH IN HEN'S THROAT (*Inquirer*).—Take the tail feather of a hen, strip it halfway down, pass it down the windpipe, turn it round quickly three or four times, and then withdraw it sharply. After this you may insert feathers dipped in turpentine four or five times per day. This will, we believe, remove the froth; and two pills of camphor, the size of a garden pen each, given for a few days at intervals of twelve hours, will cure. The two pills form one dose. If improvement justify it, diminish the dose half, and if the bird appear well, let well alone, and discontinue all treatment. We are not sure your fowls are not overfed and overfat. When such is the case, cease feeding and cause free action of the bowels. When the intestines become embedded in fat all the functions of the body cease to be performed in a healthy manner. On account of stoppage, that which should pass away returns, and aqueous matter would assume the nature of froth.

SPUR OUTSIDE LEG (*Houdan*).—It is a great disadvantage.

CRÈVE-CŒURS (*Jack*).—It is neither a disqualification nor a serious disadvantage for a Crève-Cœur pullet to lose a toe. If that is her only defect, we should exhibit her confidently. The combs and gills of the pullets depend much on age and condition. When they are about to begin laying, the comb and gills become enlarged and raddy. Some are more precocious than others, and develop these ornaments at an earlier age. It is not a disqualified pen if it consists of one pullet fully furnished and another guileless of comb and gills, but it is a disadvantage, and we should prefer to scud two without any, to sending two of apparently different ages. Large combs and gills are not essential to hens of this breed. The rough appearance about the legs is the "poultry elephantiasis." It is very troublesome, and is incurable in old birds. We have cured it in young ones by keeping the legs constantly lubricated with compound sulphur ointment. The disease came from abroad, and is very eccentric in its attacks. We have, as is duty bound, followed it and given it our best attention. We have never seen an adult cured.

FLOOR OF POULTRY HOUSE (*S. Wells*).—We do not like oyster shells for the bottom of a fowl house. We advise you to cover it thickly with road grit. That filters and is always dry. It is also an excellent dust bath, which is essential to fowls in confinement. Some mortar is very desirable, so is a plot of grass. Cinders are not good, nor is coarse gravel, in a limited space. If your fowls are forward show them, but not unless they are.

LAST YEAR'S HENS (*Hants Henwife*).—It would be a great pity to kill your adult poultry, as some of them will certainly lay as soon as they have moulted. You should now be getting eggs from your pullets. You need not be disappointed if you get but few, as this is the worst time of year, but you should have some. With pullets it is a question of age, not of season.

POWL'S LEGS SCALY (*B. B. A.*).—The only advice we can give you is to keep the fowl's legs always moist with compound sulphur ointment. It is a disease that first appeared a few years since, but has much increased of late.

ROUP IN PIGEONS (*Richard Hilton*).—The diseases of all birds are hard to cure, and no infallible Pigeon doctor has yet arisen. Prevent disease you may, cure disease you seldom can. Roup arises from cold currents of

damp air. A very able Pigeon fancier, who wrote in this Journal under the name of "FOREIGNER," says—"I have tried many remedies for roup, and I find that some Pigeons are recovered by one remedy, and some by another, and the majority recover. Some give a pinch or two of charcoal powder; some a dose of carbonate of soda, or a pinch of alum; or some a dose of flowers of sulphur." Warmth and hampseed we have known as remedies. Mr. Brent records he never had roup in his loft, neither have we, but ours is very warm.

POUTER MANAGEMENT (*Pouter*).—The house you have would do very well for these birds. Let them always have their entire liberty in it, except in very cold or wet weather, when we should advise their not being let out into the open wire aviary. Pigeons delight in sunshine, and Pouters like broad spaces of wood, like children's forms, to promenade on. Cold and wet bring trouble, but cleanliness and care will keep disease out as a rule.

TORTOISE (*Marian*).—If there is a heap of leaves in the garden it will bury itself in that heap; if not, bring it in-doors and place it in a cool cellar or cupboard, covered, but not wrapped up, by a piece of carpet. It will remain torpid until spring.

METEOROLOGICAL OBSERVATIONS

COVENT GARDEN MARKET.—NOVEMBER 16.

Good samples of fruit are now in better request, the great bulk of it being inferior, and meeting with a slow demand at low prices. Common Apples and Pears change hands at from 2s. 6d. to 5s. per bushel. English vegetables comprise Brussels Sprouts, Savoy, Spinach, Coleworts, Broccoli, and Cauliflowers, and are better now than they have been for some time.

From observations taken near London during the last forty-three years, the average day temperature of the week is 47.9°, and its night temperature 33.4°. The greatest heat was 62°, on the 25th, 1803; and the lowest cold 9°, on the 25th, 1-54. The greatest fall of rain was 1.21 inch.

THE POTATO AND ITS CULTURE.—No. 1.
THE SEED.

THE berry of the Potato is commonly called "the Potato apple or plum." When it begins to change from a green to quite a light colour it must be carefully watched, if seed from it is wished, and when it has the slightest tendency to burst it must be picked off, and laid on a dry shelf in a greenhouse; or, if there is not one, place it in any dry warm situation where the pulp will dry rapidly.

This operation requires great care, for if the apple is picked off the haulm before it has arrived at maturity it will rot, and render the seeds useless. On the other hand, if allowed to remain on the haulm too long the seeds will be shed, fall on the ground, and so in all probability the best will be lost. When the pulp has dried sufficiently, remove the seeds from the dry skin of the berry, and lay them on a board or slate, place a square of glass on them, and expose them to the sun to thoroughly dry them previously to putting them into the seed bag or bed.

On the treatment of the seed a great deal depends. If the seed has been gathered off a first-early Potato it may be sown to advantage the same season, but it will require the following treatment. A piece of ground should be selected on a warm south border, and after some good turf has been procured the operator may begin to build the walls according to the size required (of course this must be guided by the amount of seed in stock), but always keeping the front wall at least 1 foot lower than the back wall, so that when the coverings are put on the rain will run off. This done, the enclosure may be carefully cleaned and dug, and if the ground is in "good heart" it will not require manuring, but if not, I recommend the following compost:—Lime one-fourth, wood ashes one-fourth, well-decayed leaf mould one-half, all mixed together. Lime will prevent the approach of worms, which are great pests in the seed bed; wood ashes will improve the growth and the skin of the Potato; and leaf mould will serve as a nutritious manure. This manure should be scattered on the surface of the bed about 2 inches thick, and then dug in, but the quantity, as I have before stated, entirely depends upon the condition of the ground. The surface should be well pointed, and rendered fine with the spade. Drills, about 1 inch deep, may then be drawn, and in these the seed should be sown. If it is in good condition it may be sown very thinly. It is a good plan to sow only about three-fourths of the bed: for if the seed comes up well the plants may be thinned out to a reasonable distance, and transplanted on the remainder of the bed which is unsown. The drills should be about 16 inches apart, and as the young seedlings advance in growth they must be earthed up, although very slightly. The bed should be watered occasionally as the weather may render necessary.

If the autumn is cold and wet, the lights should be put on, or if lights cannot be had, make oblong frames the same length as the bed is wide from outside to outside of

the turf wall, and about 3 feet in breadth; these frames may be covered with canvas, prepared in the following manner:—Mix in a saucepan three pints of linseed oil and 1 oz. of sugar of lead with 4 ozs. of white rosin, place over a gentle fire till the whole is melted, keep it well stirred while it is on the fire, and when cold it will be of the same consistency as paint. It may then be laid on the canvas with a brush, the canvas being stretched on the frames and fastened with zinc tacks (which do not rust) previous to being dressed. The canvas will require one coat on the inside and two coats on the outside, and when dry it will be of a light yellow colour. This ranks next to glass for admitting light and heat. Where there is a cold frame, of course it does away with the foregoing method, but in either case air must be admitted at every opportunity in order to strengthen the young plants.

Seeds which are gathered from late varieties must remain in the seed bag till the following spring, as the seedlings never do well when raised entirely by artificial heat.

When the young seedlings have come to maturity, which may be seen by the haulm becoming yellow, they may be dug up, and their little tubers laid on a dry piece of ground exposed to the sun to become green and harden. When they have been sufficiently hardened and greened, they may be put in a bag and stored in a dry place safe from frost till the following spring. Each of these small tubers is "a set," and some growers say the qualities of the seedlings may be fully tested the same season as grown, but this I deny, knowing from experience that it requires another season to test them fully and accurately.

THE SET.

Next spring, on a warm south border under a wall or fence, dig out trenches about 14 inches wide, a good spade's depth, and about 18 inches from row to row, and lay the soil on the outside or right-hand side of the trench. By so doing the trenches may be placed closer together than if the soil were cast on both sides. This done, prepare an equal quantity of slacked lime, wood ashes, and well-decayed cow dung, the quantity to be applied to the ground entirely depending upon the richness and kind of soil; if very light, with a gravelly subsoil, little or no lime must be used. As this compost is put into the trenches let the soil be mixed with it, and plant the sets from 3 to 4 inches below the level of the surface, and about 9 inches from set to set; then cover the sets up to the level with the soil taken out of the trench. Before planting, every set, small or great, must have a piece cut off the end where there is a cluster of eyes; the reason for this will be found under the heading "General Remarks." If the weather be very dry a little water may be applied. If it should be frosty the soil must be drawn up to the seedlings, leaving just the head or crown exposed, and the following is a very good method of protecting them:—Procure some fir boughs about 3 feet long—the ends of boughs would be best, for they would be well feathered at the bottom—then arch the rows over with the branches, taking care to serve the ends of the rows the same as the sides to prevent

the wind from drawing up the rows. Advantage must be taken of every warm sunny day, and the covering should be taken away, which will enable the operator to flat-hoe and earth-up the rows if necessary, as well as harden and encourage the growth of the young plants. In all cases the covering should be put on while the sun is shining on the rows.

The time for planting entirely depends upon the locality. In the south and south-midland parts of England planting may be commenced in March, but in the north and north-midland counties planting must be deferred a fortnight or three weeks, but in either case the time must be left to the judgment of the operator.

As the tubers ripen, which will be seen by the haulm or tops becoming yellow, they may be forked up. Those which are ripe about the beginning of June may be termed "first earlies;" then those which ripen about July, "second earlies;" and those ripening subsequently are "late" varieties.

In examining the Potatoes, the large ones must not always be considered the best, nor the small ones the worst, but in both cases let a fair-sized, clear-skinned, shallow-eyed Potato be chosen, and let each root which is deemed worthy of being saved for culinary proof be kept separate from the rest, and let a private mark by which it may be identified be put on it. When the cooking is over, those which have a favourable report and prove first-rate in all points may be brought out as new varieties after a stock has been raised. It is a good plan to detail the characters and different qualities of every such variety, and whether it is a first early, second early, or late kind, for this prevents disappointment to the purchaser.—*J. C. Lewis, Gardener and Bailiff, Sudbury Rectory, Derby.*

CUTTING LAUREL BANKS AND HEDGES.

An inquiry was lately made about cutting Laurels, and the best time to plant them; and as in these matters many errors have at times been committed, some further details than those given in the reply may be entered into. Few plants bear the knife and saw better than the common Laurel, but it is advisable to point out when the pruning may be performed with the least amount of injury to the plant, as well as to the appearance of the shrubbery or group. There are but few shrubs so accommodating as the common Laurel in regard to the sites in which they are found to thrive; in a dry sand or a bed of the stiffest clay the plant equally continues in a healthy growing state, so it does in the black peat of a moorland waste, and in the decomposed chalk which overlies an immense depth of that material. In all these soils it remains, unlike many other plants, in a healthy state, and it will endure an amount of rude treatment under which others would succumb. At the same time it is certainly not the hardiest evergreen we have; on the contrary, some winters tell a tale on it in some places. From injury in these winters it sometimes takes years to recover, and sometimes it perishes entirely.

Planting Common Laurels.—So much depends on the character of the weather and other conditions, that it is difficult to say with certainty which is the best time to plant; for although I have planted Laurels—rather extensively too—in, I believe, every month of the year, the success and failure have been so confounding owing to circumstances, that it is no easy matter to say what time is best; but I may say that the time too often chosen for the work is about the worst, and that is the dry withering weather which often occurs in March. Better wait till May; the losses will then not be so great, as we then do not, as a rule, experience the parching east and north-east winds so prevalent in March. If showery weather occur in May, I would as readily plant in that month as in any. September is also a good time for the operation, and is better than later in the season, provided the ground is moist enough, or made so artificially. The long heavy dews, so common towards the end of that month, serve to moisten the foliage so well that the change is then less felt than, perhaps, at any other season, if in transplanting an abundance of good roots has been secured. But so accommodating is the Laurel that it is often planted in mid-winter, and, in fact, at all seasons, and in some districts it is a common saying that if planted upside down it will still grow. I recollect making many years ago a sort of fernery with the roots of trees and shrubs of various kinds, including those of Laurels, that had been grubbed-up. Many of them after having lain about a long time, grew where they were partly covered with earth; but it is not uncommon to witness large bushes taken up from a shrubbery where they had luxuriated for years, and used to stop a gap or hide an unsightly

object, turn rusty and die off soon after planting. Yet the plant does not always die when it puts on its red garb; a certain amount of life still lingers in it, and if treated patiently and left alone it would often recover in time, but the knife is too frequently called into play, and the plant dies further back than it would have done if left alone. Whenever the planting can be accomplished in September let it be done then, and the same may be said of April and May; but, if possible, avoid the dry north-east winds of early spring, as they do much harm to all newly-planted shrubs. It is, however, frequently necessary to plant at this time, and we must then be careful to secure to each plant as many roots as we can, and let them be well secured in the ground if that be at all dry and lumpy.

Cutting and Pruning.—Cutting, I consider, signifies a more extensive mutilation than pruning, as it now and then means the total cutting down of the plant. This I generally try to do in March, and sometimes as late as April; not that I advise doing the work so late, but as the shrubs operated upon are often in conspicuous places and seen every day, whatever may be the ultimate benefit, a severe cutting of evergreens disfigures them for a time, and the later it is performed the shorter time they are unsightly. With this object I seldom cut them till the middle of April, and then rarely cut them down entirely all at once, although the requirements of the plant may render this desirable; still whenever possible, a branch or two left on each plant will be of great service in securing an early and healthy growth, even if the branch left must be cut at a later period. As they act as nurses, their presence even if unsightly must be endured. I have on several occasions cut down large bushes (almost trees), of *Arbutus* which had become naked at the bottom, and by leaving a side branch or two a good bushy head was soon formed again by the growth which took place at the cut-down part, and Laurels are more prolific in buds than the *Arbutus*; but when the cutting down does not involve such severe amputations, the work can be done at another season if necessary. Much, however, must be left to the judgment of the operator, and I must content myself by saying it is rarely the plant is improved in appearance the moment it is cut; it is the better shape it is likely to assume when it has grown again that prompts the cutting, as the graceful character of the plant in its natural state cannot well be improved upon excepting when it is made to conform to a certain artificial arrangement. This brings me to another feature of the plant's utility, but before entering into it I will remark that those who have naked-bottomed overgrown Laurels that no longer fulfil the purpose they were intended for, which was to screen some unsightly object behind them, should cut them down at the proper time, and the young healthy after-growth will soon effect the object the older ones have, in fact, grown too old to do.

Pruning Laurel Hedges, Banks, &c.—Although I am not an advocate for much of this kind of work, it is, nevertheless, one of the features in many places which it would not be easy to improve; and as we have here, perhaps, as much cut Laurel to deal with as can be met with in most places, the experience of a number of years has enabled me to perform the operation in a more expeditious manner than was thought of at first, and the result is satisfactory. We have sloping banks and upright surfaces of Laurel to trim, as well as large breadths nearly flat. We have found out that to get the operation done in the quickest manner is better than taking more pains and letting the job linger for some time. Instead, therefore, of cutting over all the surface with the knife, we apply the shears, and so get over a large breadth in a short time; but it would not do to resort to clipping at all times, and I do not affirm it is better than the knife, but it is infinitely quicker, and it is important to get it all done in a short time. In our case we begin about the second week in July, and generally finish the same month, the whole being sometimes completed by the 25th. My object is as follows—Having an aversion to a closely-shaven surface, I have the Laurels cut over in time to insure a short growth afterwards of 3 or 4 inches or more, which growth hides all rawness caused by the cutting, and at the same time conceals the leaves that were cut in two by the shears. This cannot always be depended upon in many places, but with us it answers admirably, the second growth seldom exceeding the above length; and late in the autumn, when the growth is finished for the year, it is easy to go over with the knife and cut off very long pieces that stand above the general run of short leafy shoots which clothe the whole for the winter; and as these almost all ripen with us, the appearance is all that can be desired, as fully formed leaves terminate every shoot.

The whole thus presents the shape of the object it is meant to represent. The looking over in the autumn to cut away any irregular growth is really so very little, that the July clipping may be said to be all the Laurels get, and more is not required. A later period of cutting may suit certain places, but this one can find out after the first season, for if cut too early the after-growth is more than is required, and if too late there is not sufficient growth before winter, or what there is may not be ripened.

To those who have the time and inclination to cut Laurels with the knife, I may say that to do so nearly all the shoots below the eye ought to be severed in such a manner that their cut surface may be concealed, and not staring on in the face. A little practice will enable anyone to cut them so as to conceal all the cuts made, the cuts looking downwards instead of upwards. In this case no leaves need be cut through, but we have never had time to use the knife. Those who have but little Laurel-cutting to do, and have let the time pass for using the shears as described, and still wish to have a suitable second growth, had better adopt the knife-and-thumb practice. They will then with a little care make very good work.

I always treat Box edgings in the same way as the Laurel hanks—viz., cutting them so as to get a suitable second growth again to stand the winter; only in the case of the Box-edging I try to get the work done in showery weather if possible, as it becomes very brown if clipped in dry hot weather. The Laurels, however, from their more robust growth withstand the drought better.—J. RONSON.

GROUND LEVELLING AND PRACTICAL GARDEN PLOTTING.—No. 6.

DRAWING PLANS.

Fig. 24.—Form a square on the diagonal line *AB*, which is done by bisecting the lines as described in fig. 6. Make line *CD* equal to line *AB*, which can be done by taking the length of one side of the line *AB* from the centre, and dotting out the same length on each side of the centre of the line *CD*. Then draw the square *ADBC*. From the sides of the square form isosceles triangles *e, f, g, h*, which is done by drawing an arc in *e* with the radius *Ac*; also with the same radius from *c* draw an arc cutting the former one in *e*; and draw lines *Ac* and *Ce*, as shown by the dotted line. Find angles *f, g, h*, and *h* in the same way. Divide lines *Ac* and *Ce* into two equal parts; with radii *es, gr*, and *nm* draw the arcs as shown in the figure; also with radius *At* draw the arc as shown in *t*. Then draw the small portion of a straight line between arcs *r* and *t*. Draw the other parts of the figure in the same manner.

Fig. 24.

Fig. 25 is another application of the square and isosceles triangle. Draw the square and isosceles triangle as before described and shown in angle *A* *c* and *r*. Draw the diameter lines *EFGH*; from point *A*, with radius *AO*, draw arc *o* until it meets the sideline of the triangle, as shown where the line is cut. From point *m*, with radius *mn* draw arc *n*, uniting with arc *AO* where the line is cut, and touching diameter line *EFG* in *u*. The other parts of the figure are drawn in the same way when centre *m* is found, so that arc *n* unites with arc *o*, and touches the diameter line in *u*. All that is necessary is to draw a circle from the centre of the square, as shown by the dotted circular line, and cutting point *m*; find the distance from *u* to *m*, point out the same distance on the other side, as shown in point *g*;

Fig. 25.

with radius *gb* draw arc *b*, which will unite with the arc drawn from *c*; and so on, until the figure is complete.

Fig. 26 is drawn from line *AB*. Draw line *An* any length; find the centre of the line, as point *c*; and on each side of *c* point off two equal parts, as *aa*. With radius *ab* draw arc *b*; with the same radius from point *c*, which is where arc *ab* cuts

Fig. 26.

the base line *AB*, draw arc *d*; with the same radius from *e* draw arc *f*; with radius *gh* draw arc *h*. Where the arcs drawn from *aa* cut each other, as shown by the dotted lines, are the centres from which arcs *n* and *o* are drawn, as shown by the radii *ko* and *mn*.

Fig. 27 is drawn from rectangle *ABCD*. The rectangle is found in the following manner:—Draw line *DA* and erect perpendicular *AB*. With *D* as a centre and the radius *AB*, describe an arc. With *B* as a centre, and the radius *DA*, describe another arc, cutting the former one in *c*. Draw the lines *BC* and *CD*, and the rectangle will be complete. Divide line *AB* into two equal parts, also lines *BC*, *CD*, and *DA*. From point *c*, with radius *ef*, draw arc *f*; from *D*, with radius *DC*, draw arc *c*; from *g*, with radius *gh*, draw arc *h*; and so on with the other sides. Draw the straight lines as shown between arcs *c* and *f*.

Fig. 27.

Fig. 28.

Fig. 28 is another application of the rectangle. The sides are divided into four equal parts, as 1 2 3 4, and the arcs drawn as shown by radii *1a* and *b2*.—M. O'DONNELL, Gardener to E. Lecming, Esq., Spring Grove, Richmond.

PEAS.

RECENT numbers of the Journal have given us some interesting matter on Peas. The subject of Peas seems ever welcome, and there is an old saw amongst gardeners, that to have plenty of Peas is never to be scarce of vegetables. If this is not all truth there is much of that virtue in it. Transpose the axiom and we see what cannot be denied, that to be scarce of Peas is to be terribly scarce of vegetables. Any information, then, which can ward off this ugly scarcity and insure a better supply and a better selection of this, the most esteemed of summer vegetables, is sure to command attention.

It may not be profitable, perhaps, to discuss the identity of Ringleader and First Crop Peas. The fact of both the eminent firms of Sutton and Carter having decided the question, one might think sufficient authority. The fact that other cultivators find a difference may reasonably be accounted for in their failing to secure pure stocks of seed. My experience is clearly in favour of the identity. I have grown them side by side, and, indeed, both kinds in the same row, the seed having been procured direct from the respective firms, and it was impossible to detect the slightest difference in any one point.

As to the heights of Peas, it would be as well if dealers would banish orthodox heights. First Crop and Laxton's Supreme

have both proved themselves ignorant of the statute of limitations. Three years ago I had the First Crop and Ringleader above noticed fully 3½ feet high. I know this is above the ordinary height. Peas, like other things, are affected by circumstances, hence it is as well to speak approximately.

It is generally admitted that this variety of Pea, whichever name it bears, is the earliest Pea known. It is also one of the most productive, and in some localities is all that can be desired as an early Pea. Another early Pea of the first order is Dickson's First and Best. In the particular soil I have to deal with, I find it the most satisfactory of all early Peas I have tried. It is not so early as Ringleader by three or four days, but for good pods and plenty of them, and for robust growth and constitution, it is unsurpassed by any Pea of its season.

I do not propose to take in review a long list of varieties. It is easy to err in growing a multiplicity of kinds. A useful and reliable variety for general cropping I find in Princess Royal. It is a good hardy sort and never fails to do its duty. Sown at the same time, or a day or two before the early ones, it comes in well in succession, and so does Champion of England, which is a few days earlier than Princess Royal and Veitch's Perfection, two Peas which have few superiors.

I grew Maclean's Premier last year for the first time. I am satisfied it is a Pea of sterling merit. It is very robust and stood the hot weather of last summer better, far better, than any Pea in the garden. It was sown at the same time as the others above mentioned, and proved the most really serviceable of any. It is a few days later than Veitch's Perfection.

Premier and Ne Plus Ultra are capable of doing all that is required of late Peas. For very late pickings, early ones sown in July are the best to be depended on. This year I let a few of the First and Best ripen on the haulm. I gathered and sowed them on the 13th of July. They have proved very useful. I gathered the last dish on November 7th.

The nature of my soil is very light, and the district is visited with a low rainfall; indeed, on an average, if it has not the lowest rainfall in England, there is only one exception. I have under these circumstances found it no child's play to keep up a regular supply of Peas during the past two seasons. Deep trenching alone would not have done it. Supplementary to deep trenching of the ground, I resorted to sowing in trenches, and leaving the Peas to grow as it were in miniature ditches, which once a-week were filled with water. By these trenches I could effectually irrigate the crop. I mixed a little salt in the water, sufficient to give it a distinct saline taste, and was rewarded with a fair supply of Peas, and not a vestige of mildew. After watering I gave the trenches a dusting over with dry soil to arrest evaporation. I had a few rows sown on the level and earthed-up, but found it absolutely impossible to get sufficient water to the roots, and they did little or no good.

I have reason to speak well of the furrow-system of growing Peas, and not Peas only—Beans, Carlinflowers, and almost all other crops were similarly treated, and the plan passed me through two very trying seasons in a far more comfortable manner than if I had not adopted it. My advice to those similarly circumstanced to myself is, Trench deeply, and sow and leave the rows in hollows, instead of sowing on the level and earthing up. I sow none on the level but the earliest crop.
—J. WRIGHT, *Gardener to Hon. J. L. Melville.*

GRAPES IN DALKEITH GARDENS.

On reading the report of Dalkeith Gardens by a correspondent in your number of October 27th, I observe that there is no mention made of the White Lady Downe's Grape. Having paid a visit to these gardens on October 28th, I saw this Grape in great perfection, growing side by side with its parent, the black Lady Downe's. I feel satisfied that when this fine Grape shall have become more generally known, it will be the favourite late white Grape. I can confirm all that your correspondent has said relative to Pines, seedling Grapes, &c. I noticed some of the latter showing immense sized bunches and berries. The Golden Champion is there growing strongly; it is a grand-looking Grape, and is of excellent flavour. I also saw some excellent bunches of the Alicante. I grow the Calabrian Baisin Grape noticed by your correspondent; it is a good late Grape.—ROBERT FLEMING, *Gardener to Richard Houghton, Esq., Sandheys, Liverpool.*

DECEIVED ROOKS AND VIOLETS.—Letters have been published lately speaking of rooks in various parts of the country re-

pairing their nests at this unusual period of the year. The Violets in the hedgerows in this neighbourhood seem also to have been misled and induced to believe that spring had arrived, as they are now in full bud, and if the weather should continue open, will be in flower in a fortnight, as they are already showing colour.—E. C., *Oakham.*

NOTES MADE DURING A TOUR IN IRELAND.

No. 3.

THE PHOENIX PARK, DUBLIN.

MAGNIFICENT, in truth! Wonderfully grand and expansive is Phoenix Park, Dublin! All Ireland is justly proud of it. In comparison with it our great London parks sink into insignificance in all the elements of natural beauty and grandeur; and, as regards extent, the Phoenix might engulf any two of them, and there would still be room to spare. The Phoenix Park forms the west-end of Dublin, on the north side of the muddy Liffey. It is here all the great officers of the state reside. Within the park various portions are enclosed—splendid domains indeed, for the residences of the Lord-Lieutenant, the Chief Secretary, the Under Secretary, and the Ranger, my friend Mr. Charles McDonald (all of which will be separately noticed), besides many other government establishments; also the police barracks, where some eight hundred young Irish police are trained, and the Hibernian Schools, where many hundreds of young Irish boys, the orphan sons of soldiers, &c., are educated and trained for soldiers again. This is a noble institution. There are churches, and schools, and teachers for the Catholic boys, as well as for the Protestants. On the Sunday, in company with Mr. McDonald, I attended the church of the latter, and was much pleased with the demeanour of the boys. What a boon it is for these poor boys to be educated and cared for thus, instead of being allowed to grow up in idleness, misery, and crime! After deducting all these enclosed policies, the extent of Phoenix Park is somewhat more than 1700 acres.

From the Dublin end to the other is a grand avenue, nearly three miles in length, and almost straight. About the centre, where several avenues intersect each other, is an imposing pillar with a figure representing the phoenix—that mythical bird. This was erected by the celebrated Lord Chesterfield, who laid out the principal parts of the park, and did so much generally for Ireland. The avenue is one of Decimus Burton's, and much more modern; it is nobly and well proportioned, marred greatly, however, in my opinion by the stiff and formal style of the planting of the trees in round groups, placed opposite each other. Many of the trees, too, are evidently ill-suited for their position, being chiefly American Limes, which, although they have been planted many years, are yet low and stunted. Limes are very much over-rated avenue trees; excepting in good moist soils and sheltered situations, they should never be planted. How immeasurably inferior to the Planes and Elms! Just alongside there are large, old, and magnificent specimens of the Dutch English Elm, forming part of the old avenue. How grandly they look, and how beautifully they have been planted in blocks of eight, forming an irregular yet continuous line, giving one an idea of immense extent. The planter of these trees was a true artist. The style of the planting of these trees completely puts into the shade the more modern attempt. With the exception of these splendid Elms, the trees of the park are in no way remarkable. Numerous attempts at planting groups and masses of trees here and there have been made, but in general with little success. The situations where trees are wanted are somewhat exposed, and the soil is dry and gravelly, so that it is a work of some difficulty to get the trees established. Several lamentable errors of judgment in the selection of the suitable varieties of trees in recent plantations were apparent; Ash, Larch, &c., being frequently planted on the dry gravelly banks, where such trees are as likely to grow as if they were planted roots uppermost. It would also be far better to plant smaller trees in such exposed places. Long spindly subjects planted in such situations never succeed. The natural tree of the park is the Hawthorn. There are thousands upon thousands of them, splendid trees too. In September they were covered with their red berries. How exquisitely sweet and charming they must be in their white dress of May and June; the whole air must be loaded with their perfume. Here, then, is the tree to plant in the exposed places; at all events, as nurses, until they become established, to others greater and finer. Much, however, may be

done with the many beautiful varieties of Thorns. There is ample room for Mr. McDonald to display his skill in planting, and earn himself a name in Ireland. I should advise him to take in hand our great London tree, the Occidental Plane, by far the finest, and noblest, and most suitable of all our park trees. I was told that the Planes had been tried and found wanting. I did not observe a single specimen anywhere in the park proper, yet in the Chief Secretary's grounds there is a large and fine example, proving that it will succeed if planted properly and cared for in its young state. Conifers might also be introduced in some of the dells and hollows to give variety. That they will succeed is proved by the numerous fine specimens round Mr. McDonald's own residence at Whitefield Lodge, which were the pet trees of the late Mr. Wilkie, for so many years chief ranger.

Of the general features of the park it is difficult to give any very correct idea. The extent, as already stated, is very great, affording excellent pasturage for numbers of deer and cattle. In the park, also, grand military reviews are held, and it is a noble place for them, there being open spaces of many acres where troops can manoeuvre to much advantage. On the southern side the ground undulates considerably, and here there are many naturally pretty spots with splendid views of the surrounding country, and the Wicklow hills in the distance. This is the place to roam and wander on sunny knolls and in shady dells—

"Beneath the milk-white Thorns
That scent the evening gale;"

yet, singularly enough, it is the least frequented. But then the Irish people do not walk or wander about; they all ride in their everlasting cars. This is a singular feature of the Irish character; they take all their exercise riding and driving, not walking. Near the principal entrance on the left-hand side stands a massive monument in granite to Ireland's greatest hero—Wellington; it is not by any means handsome, yet is attractive by its very ponderosity and hugeness, resembling, as the Irish critics say, "an overgrown milestone," and by no means a bad comparison.

Opposite to this monument on the right-hand side of the entrance lies the People's Garden, "a rare pretty place," as the carman told me, "with lots of flowers." "That was made in Lord Abercorn's time. He was a good man; he was the man for Ireland," he continued to observe, finding I was a stranger. This People's Garden is a small enclosed portion of some few acres, where a first attempt has been made to introduce the ornamentation of flowers, &c., as in our London parks. It is but an attempt, and as such it is scarcely fair to criticise it too severely. It would be scarcely possible, however, to conceive anything in worse taste. The situation is the top of a high ridge, and the principal features consist of several patches or mounds of loose stones with soil representing rocky mounds; on these many expensive plants have been placed, which of course soon die. These mounds have a very paltry appearance, and Mr. McDonald should lose no time in sweeping them away. In the hollow by the water close at hand something very pleasing might be effected with the stones referred to. A few flower beds are cut out here and there on the grass, but without any style or order, and these were planted with Pelargoniums, Calceolarias, &c., in an equally biggledy-piggledy fashion. I must except several magnificent beds of the dwarf Chrysanthemum-flowered Aster, which were the most effective beds of Asters I have ever seen; but the Aster is a plant not at all suited for such a prominent position, as it is so late in flowering, and lasts but a short time. There were one good group of the dwarf Dahlias, some good Gladioli, and a bed or two of Mrs. Pollock Pelargonium with *Centaura ragusina*; but of the general arrangement of the design as a whole the less said the better. I thought, if this is "rarely pretty" I am a poor judge, or the Irish people are easy to please. There is a grand opportunity for Mr. McDonald to remodel this, the People's Garden. What splendid scope there is, too, in the lower ground between it and the zoological gardens. A fine broad walk should here be formed straight through, and groups of Rhododendrons and other shrubs introduced. This part could be formed with great ease into one of the loveliest of spots, and at no great expense. A few of the trees, which are here pretty numerous, tall, and fine, would perhaps have to be removed, but that would be no loss, but the contrary.

Phoenix Park as a public park stands almost unrivalled, but it wants embellishments. More trees are required to afford shelter and enhance its beauty; and of the People's Garden, if it is to be worthy of the name of the park in which it is

placed, and of the good people of Dublin for whose pleasure it is maintained and was created, it must be greatly altered and extended. It rests with Mr. McDonald to suggest and plan for all this, and for a liberal government to enable him to do his duty to the good people of Dublin.—B.

BLANCHING CELERY.

THERE are many people who take vast pains to grow Celery, but beyond throwing a little earth up to it towards autumn the blanching for the most part has to take its chance. Preparing for table, or what I call putting on the finishing touch, is regarded too lightly, for there is no comparison between a well-blanching head of Celery and one that is not so. The former has a transparency which recommends it, for it looks well on the table; one may be tolerably sure it is tender and sweet; and its crispness shows plainly that the cultivator knows what he is growing it for. The latter is almost certain to prove more or less rank-tasted and tough, with only a small portion of the heart at all palatable, the remainder being only fit for soups or to be thrown away. I need hardly point out the waste of time and labour when the crop is in the condition I have just noticed, but I may remind those careless in such matters that there is probably no kitchen-garden crop more creditable than a thoroughly well-blanching lot of Celery.

In a deeply-trenched and well-worked soil earthing Celery is not much trouble, because there is no lack of fine earth to place round the plants; this should be pressed to them with one hand, while the other hand should be used to hold the plant upright and keep the leafstalks straight and close, so that no earth may penetrate to the heart of the plant. Afterwards the bulk of the earth may be added with a spade. In heavy stubborn soils the work of preparing the soil for earthing-up must be carried on regularly during the summer, and, if at earthing-up time it is not sufficiently broken up to apply next the plants, some soil must be prepared. I have used burnt earth and old potting soil with advantage, but it must only be very moderately moist, or finely sifted coal ashes are remarkably good substitutes; these will also keep the stems free being marked by worms, slugs, &c.

It is very rare to find Celery taken out of the earth so clean and free from the markings of wireworm, and the like as it is this autumn. I attribute this to the dry weather having either killed such pests, or sent them down into the earth, where there is more moisture, and from whence they have not yet returned.—THOS. REED, *Hatfield Park.*

THE BOVINIA POTATO.

MUCH has been written about that monstrous Potato, Pater-son's Bovinia. I procured 1 lb. last spring, which consisted of one large and one very small Potato. I carved these into bits with one eye to each, which were planted April 4th under by no means favourable circumstances, being, for lack of a better available site at the time, planted between two rows of Raspberries, the spreading roots of which must have drained the soil of much that might have gone to the support of the Potatoes. Nevertheless, on taking up and weighing the crop a few days ago I found the weight of Potatoes to be 84 lbs., some of the tubers weighing over 3 lbs. each. The largest Potatoes were the oddest and most wonderful-looking objects imaginable, the oddness of their appearance being greatly enhanced by their having supertuberculated to a considerable extent, the clusters of young Potatoes (some of which were of a large size) sticking about these monster tubers in all imaginable forms and shapes. I think it will prove essentially a cattle Potato, being so deep and many-eyed, and by no means handsome, though on trial the flavour was found to be very tolerable.—W. HURSON, *Chase Cliffe, Derby.*

WORMS IN POTS.

FLORISTS are very anxious to exclude worms from pots, but orchard-house cultivators seem to consider them as of no moment; yet one must suppose that they are as injurious to the roots of Strawberries and Pines as to other plants. Where pots stand on the bare earth it is impossible to keep out the worms, which foul the drainage, in addition to disturbing the roots; for this reason I always now set my pots on tiles. But worms or their eggs still get inside the pots in the compost, and I should be glad to banish them altogether; also the large yellow slug, which I often find among the crows. Now, lime

water is the remedy commonly recommended, but I observe that the Rev. J. Wood ("Garden Friends and Foes") says that lime is by no means so effectual as the carbonate of ammonia. He further urges the advantage of the ammonia as a manure. Of the efficiency of this remedy, if the solution be strong, I cannot doubt; but I should be glad to know from any of your readers who have actually made the experiment what is the extreme strength which the roots of ordinary plants, say the Strawberry, will bear. Would 2 ozs. to the gallon be excessive? I have tried carbonate of soda at this strength, but only to see its effects on worms. It did not seem better than lime water.—G. S.

FRUIT TREES FOR SMALL GARDENS.—No. 2.

As to the form of fruit trees for small gardens there can be no two opinions. Standards may be all very well for orchards, and where the cultivator does not set much value on his land, or has no eye to an early profitable return. If he care not for quality, and for planting for another generation, he will have an orchard. He may have fruit in seven years that will, perhaps, pay the rent of the ground, fruit that must be sold by measure, for it is not of a quality to have a value individually, and which if it is to be disposed of must be parted with at a cheap rate. It is not of orchards, however, that I wish to write at present; they are good in their place—for those who have ground to spare and can afford to wait—but I may state my conviction (undoubtedly a strange one for a gardener who has planted and is planting orchards), that orchards are not the most profitable and best means of growing fruit, quality as well as quantity being taken into consideration. It is all very well to look at an orchard in autumn when the trees are laden with fruit, but no one takes into account the time the trees were planted before any return was made, and it seldom occurs to many that the crop is always at the mercy of a gale of wind. There is much uncertainty from frosts destroying the blossoms, from the wind blowing off the fruit just when it is fit to gather; or if not, the danger of one branch laden with fruit rubbing against another causing much damaged fruit; besides, the trees are beyond easy control.

For gardens of whatever size, great or small, the peer's or the peasant's, there can be no question as to the form of trees. Standards, we know, usurp the whole of the ground in which they are planted, and render not only the ground over which their branches extend, but that for a distance beyond, wholly unfit for the successful cultivation of anything else. In a garden we expect something more than fruit trees, everything to stand on its own footing, everything to be good of its kind, everything to yield a good return for the ground devoted to it. I can recollect passing my first year as master gardener in a place where standard Apple, Pear, and Plum trees were at no very great distance apart, and my having to grow bush fruit (often under the standard tree) and vegetables in the spaces getting a gleam of sun. There could be no excuse for retaining them, as there was a capital orchard, and the walls were covered with good and useful trees. To ask the proprietor to clear out the standard trees would have been equivalent to asking him to cut down the fine old Oaks in the park. He had his old notions. It was folly to advise dwarfs or espaliers; the former would grow quite as big, it was only a question of time, and the espaliers would need to be so cut-in that they would not bear. He neither believed in root-pruning, nor in summer-pruning. Is not this applicable to our farm and cottage gardens? Are they not as a rule orchards, not gardens? Fruit there may be from the forest-like trees, but what of the quality and of the value of the ground for garden purposes? Large quantities of some kinds of fruit are in some establishments only useful in gratifying a class who care not whence a thing they like is obtained if they get it, or such fruit is left to decay in the fruit-room. In farm and cottage gardens this may not be the case. The fruit may be disposed of as the owners think profitably.

The objections I have to urge against standard trees in gardens, and especially small gardens are—1st, They take up too much room. 2nd, Their shade, the drip from them, and the roots, render the ground unfit for anything else. 3rd, Often a larger quantity of one kind of fruit is produced than is sufficient to meet all the demands required. 4th, There must be a want of variety which is always pleasing when good, as well as an inferior quality of produce in everything, for standard trees do not yield nearly so good fruit as espaliers, bushes, and pyramids. In these days quantity is of no use unless combined with quality. I might go further and say standards are

not profitable, or if they are, less so than pyramid and bush trees.

For gardens I am convinced of the inutility of standard trees, and in no case would I grow anything larger than a pyramid. I may be thought peculiar in my views, but I say that in this country pyramids of over 7 feet 6 inches, or, at the extreme, 8 feet, have their days numbered. Above that height they are too large for gardens and shade the ground, and they have a tendency to lean to one side, especially those on the Quince stock, and the fruit on the upper part is liable to get damaged by wind and the blossoms by frost if the situation is at all exposed. In an exposed situation I consider bushes preferable to pyramids, though there is no objection to pyramids of 7 to 8 feet high.

Pyramids and bushes of Pears, Plums, Apples, and Cherries are what I think most suitable for small gardens. Walks there must be in every garden; and on both sides of them I would have in all cases a row of pyramid or bush fruit trees in kitchen gardens, and even in the ornamental part of farmhouse gardens I would introduce them as specimens, whether on grass or in borders. On grass they would do well with a space of 4 feet round each kept clear of grass, and for applying top-dressings of rich compost so necessary for pyramid and bush fruit trees. A row of Pears, Apples, Plums, and Cherries on both sides of a main walk, planted at 9 feet apart, and standing in 4-foot circles at 6 feet from the walk, would have a fine effect—all blossom in spring, and laden with delicious fruit in summer and autumn. In a kitchen garden the trees need not be so far apart: 6 feet would be ample, but not too far. Nor would I stop there. In the place where the Box or other edging was I would have a galvanised wire (No. 6) strained exactly 1 foot from the ground; and if I had an edging at all it would be of tiles; equally distant from the trees on the other side I would have another wire strained. For training on those wires I would plant double cordon Apple or Pear trees 12 feet apart, so that each cordon would have 6 feet length of wire to occupy. The cordons might be either Apples or Pears according to the wishes of the occupier, but as Apples are the more useful fruit I would prefer them. By thus disposing the borders along the sides of the walks and planting with pyramid and bush fruit trees, there would be a sufficient supply for a family. It is presumed the garden beyond this is sufficiently large to afford space for a proper supply of vegetables. As a rule, the space devoted to fruit will be about one-third that of a vegetable and fruit garden combined.

Of course in gentlemen's gardens the walls must be taken into consideration, but taken altogether, the trees against walls, and those in borders and in the quarters occupy about one-third of the kitchen-garden ground. For farm and cottage gardens, however, I consider borders on both sides of the walks, or, it may be, one walk would afford a sufficient supply of fruit; but if not, and there were more ground than was wanted for vegetables, the part not required could be planted with bush and pyramid Apple, Pear, Plum, or Cherry trees at 6 feet apart every way to bear fruit either for family use or for sale, for it is only right that those occupying garden ground should make it profitable to themselves, what is not required being sold.

But who would advise planting bush and pyramid Apple, Pear, Plum, and Cherry trees as a paying speculation? Every one who has the scales of prejudice removed from his eyes, as he will have if he plant an equal extent of ground with standard trees, and with bushes and pyramids for comparison. It is usual to compare the produce of a few bush and pyramid trees but a few years old with those of standard orchard trees that occupy the whole of the ground devoted to the bushes and pyramids, and vegetables as well. Some have an idea that a small tree should bear as much as a giant, but take no account of the ground occupied in each case, nor do they consider the difference in the ages of the subjects. They expect a pyramid or bush tree, requiring at the most 4 square yards, to give as much fruit as a standard on from 36 to 64 square yards. Nothing is expected from a standard for the first two or three years; but a bush or pyramid is expected to do wonders the first year, and, if it do not, those whose advice prompted its planting suffer.

The only satisfactory way to come to a conclusion is to plant a piece of ground with standard trees, and an equal extent with bushes or pyramids, and note the annual produce of each. That is what I have done, and I advise others to do the same if they wish to become acquainted with the most profitable mode of growing fruit of superior quality. Let them prepare an acre of ground for bush and pyramid fruit trees. It ought

to be trenched; that will cost—say 1d per yard, or £10 1s. 8d., and the cost of the trees (1210) at 6 feet apart will be, for Apples, £99 15s., at 1s. 6d. each; also for Pears and Plums; but for a quantity like that they may be had for considerably less money. For properly planting, £3 will be required, for there is a great difference between planting and cramming a tree in the ground. The total expense will be £103 16s. 8d.—an outlay at first equal to the value of the ground, and for the first year we shall require manure for mulching, and for enriching the soil—say £5. The return the first year I will pass over, though the trees will do something. The ground being occupied with Potatoes will pay for the manure, and the cost of trenching will be returned as well as the labour of attending to the trees; but I will be moderate, and say the cost of the planting instead of the trenching will be repaid. This will bring the first cost down to £100, pay 5 per cent. on that for the outlay and rent, for both of which we require £10, £5 for manure, £5 for labour, or £20 from an acre of Potatoes. In trenched ground the Potato crop will do that and much more. The fruit, as said before is given in, though I have known the trees average half a dozen, which would give 7260 for an acre, or 100 pecks that would sell anywhere for £7 10s.

The second year we drop with Potatoes, they are excellent for keeping down weeds, and require "muck," the very thing wanted. They would pay the wear and tear, rent, interest of outlay, and leave the fruit for repaying the expenditure on the capital account, though we have paid the interest on it. Well, the second year they will average a dozen fruit each. I will put them down at 300 pecks at 1s. 6d., £22 10s., and our capital stands at £77 10s.

The third year we have the Potatoes for the last time, pay interest, rent, and labour, &c., as before, and will have a produce of fruit equal to a peck per tree. Where can we see trees at three years after planting giving a peck of fruit? I had such this year, and have the fruit now of Cox's Orange Pippin, for example, in Apples, and Marie Louise and Beurré Hardy among Pears, and I had Plums, also Cherries, at three years old, which, if not yielding a peck of fruit, have given as many pounds as there are quarts in a peck. This may be an exceptional year, but I have for the second time found what I have stated correct of trees at three years after planting. I will say 1210 pecks, at 1s. 6d., £90 15s., which will clear off the outstanding capital of £77 10s.

From three to seven years after planting the produce will rise from 1 to 2 pecks, many trees at seven years producing a bushel of fruit; but from three to seven years I will average the produce per tree at 1½ peck, or 1815 pecks per annum, which at 1s. 6d. will amount to £136 2s. 6d.; after paying all expenses this is cent. per cent. profit. At seven years they will bear 2 pecks each—2420 pecks at 1s. 6d., £181 10s.; the seven years' produce will be:—first year, 100 pecks, £7 10s.; second, 300 pecks, £22 10s.; third, 3210 pecks, £99 15s.; fourth, fifth, and sixth, 1815 pecks, £136 2s. 6d. each year, or collectively £108 7s. 6d.; and seventh, £181 10s. The whole value of the seven years stands at £710 12s. 6d.! Cent. per cent. on the outlay, and but a fraction short of 10 per cent. on the land, which is never calculated at more than 3 per cent. [We think our correspondent has made too little allowance for failures owing to season and other causes, and has placed too high a value on the produce.—EDS.]

The produce will increase from the 2 pecks at seven years to a bushel at ten years and often twice that, and, as far as I know, will endure a generation, for the short duration of Apples on the Paradise, and Pears on the Quince I believe to be purely imaginary.

Let us plant an acre of orchard, which at 21 feet apart will take about a hundred trees; these at 1s. 6d. each will be £7 10s., planting about £1, or £8 10s. in all. The first, second, and third years there will be grass, paying the rent perhaps; but as for fruit they will be few and far between. Nor is the produce in the fourth, fifth, or even sixth year much better; seven years must elapse before we can calculate on a peck, and that is quite as much as can safely be done, and then we have just the first cost of the trees. Another seven years will be needed to bring them level in produce with pyramids and bushes at three years, and another seven years will be required to get them into a condition to give as many pecks of fruit as are produced by the others at seven years. The produce of an acre of orchard trees is thought something extraordinary when it reaches 2000 pecks, representing a value of £150, which must not be looked for under twenty-one years, and that is less by 40 pecks than the pyramids and bushes will give at seven years.

There is one more point—the fruit from standard trees is not so fine as that of pyramids and bushes, and not produced with such certainty. It would be difficult to explain why this should be, but I find the nearer the ground any fruit is, there being no higher branches usurping all the vigour, the finer is the fruit. Cordons at 1 foot give finer fruit than espaliers at 4, 5, or 6 feet, and the fruit of pyramids is more uniformly large and good than that of standards.—G. ABBEY.

SALVIA VIOLACEA.

This annual is commonly known in our gardens under the name of Purple-topped Clay. Most lovers of a garden know the plant, yet how seldom do we see it grown, except in some out-of-the-way corner!

Treat it well, and bring it to the front of the borders and shrubberies, and it will be justly admired.

The culture of this *Salvia* is most simple. Sow the seed early in spring in any light garden soil, and transplant the seedlings, when they have made a few rough leaves, into the flower borders or fronts of the shrubberies. Everyone must admire the beautiful purple leaves on the tops of the flower shoots. It has also the great merit of lasting a very long time in perfection. The enclosed shoots are from the open borders, so you will see the plant, although a native of Mexico, is not at all a tender subject.—J. SMITH, *Exton Park, Rutland*.

THE PILLAR ROSE.

PERHAPS there is no form of the Rose more effective than the pillar Rose, and if this method of fashioning the Queen of Flowers was more thoroughly understood, Pillar Roses would probably be more plentiful in our gardens.

A pillar Rose when fully grown should be 8 feet high, broader at the base than at the summit, and in the blooming season it should be clothed with flowers over its entire height. The Hybrid Chinese and Hybrid Bourbon are the best kinds for the purpose, on account of the masses of large brilliant flowers which they produce. The Ayrshires, Sempervirens, and Bourbons stand next in order of merit, and these will attain the height of 10 feet or 12 feet if required; while the strong-growing Hybrid Perpetuals, Noisettes, and Bourbons, are available in positions where a maximum height of 6 feet suffices. The three latter groups, however, offer fine varieties that will form well-furnished pillars more than 6 feet high, and they bloom only by dribbles after the first flowering; still, where it is desired to have flowers in the autumn, rather than in the summer, they may be preferable, and they form by no means inelegant objects.

Pillar Roses may be planted singly on lawns, in groups, or in avenues, and in the latter case, if the walk is of grass the effect is materially heightened.

It is by no means difficult to form a pillar Rose; time and patience are the chief requisites. Choose from the nurseries the tallest and strongest plants, whether on their own roots or otherwise, and here, as elsewhere, be sure to obtain suitable sorts. This is a point of primary importance, and no amount of skill and patience will avail if it be neglected.

After the plants are fairly set in the ground, some recommend cutting back the shoots to one or two eyes, to induce the formation of a few strong shoots the first year. I have no grave objections to urge against this practice, and if the roots have been injured or curtailed in removal I recommend it; but under other circumstances my experience is in favour of leaving the plant unpruned the first year, or at the most restricting the operation of pruning to the removal of the weak, misplaced, and ill-ripened wood. Tie up the shoots to a neat stake immediately after transplanting, and the first growth springing from the top will further extend the height of the plant. This completed, the second or summer growth will probably arise from eyes nearer the base hitherto dormant; and while the former were weak and short, terminated with flowers, the latter will be vigorous wood-shoots, available for forming the plant, and giving flowers the next year. Pruning and training are the principal means by which we expect to carry forward our operations with success; but manuring must not be neglected. Be it remembered that a pillar Rose has more to support and develop than a dwarf or standard, and a liberal diet should be accorded to it. Manure twice annually in February and July; and if convenient, water frequently with weak liquid manure in the growing season, especially in dry weather.

But we have something to say on pruning and training. When

the plant has been a year or more in the ground (in the spring of the second year) pruning is absolutely necessary. Cut all weak, ill-placed, and crowded shoots, and shorten back such as are indifferently ripened to the first solid eye, taking care not to lower the height of the plant more than is necessary in carrying out these principles. The well-placed and well-ripened shoots should be pruned sparingly or moderately, in no case severely. After pruning, tie the branches round the stake with willow-twigs or tar-twine.

The operations of manuring, pruning, and tying, are to be repeated from year to year. About the third year the stake may be replaced by a small birch pole, with the snags left protruding some 6 inches from the sides, which have a pretty rustic appearance, and serve to protect the branches from the action of the wind. Thus is the pillar Rose formed, and few objects in the garden present a more gorgeous appearance.

When the pillar is five or six years old, now and then an original and main stem will show signs of debility. Such should be cut away close to the ground, and replaced by the young shoots which occasionally spring up at or near to the ground line. By this practice the plant is rejuvenated and retained in perfect keeping over an indefinite period.—WILLIAM PAUL, *Paul's Nurseries, Waltham Cross, N.*

USING FRUIT HOUSES AS PLANT HOUSES IN WINTER.

NOTWITHSTANDING the importance of the rule, "Have a place for everything, and keep everything in its place," there are few gardens, even the most extensive, where such a rule is not continually, and as a matter of course, broken. All sorts of summer and autumn fruiting houses are too much crammed with bedding and greenhouse plants in the winter months. Our earliest Peach house has now all its shelves filled, also every available space from wall to wall, except about 1 foot in width left as a pathway. We consider it better that before this thorough cramming with small plants, the Peach trees should have had a touch of frost, as they had this season, but frequently the trees have never felt frost, which is chiefly useful as helping to destroy insects, though we have little faith in even a severe frost doing much injury to the eggs of the insects which generally annoy us. We have some hope that the eggs of tropical insects may suffer, though, as lately stated, we have known instances where exposure to a keen frost did not destroy the mealy bug of our stoves. We may say the same of vineries; as soon as the fruit is cut and the houses cleaned, they are generally filled up with plants to be brought on for other places. These places being heated, very little heat applied keeps the plants safe, and saves a vast amount of labour if the plants must otherwise be kept in cold pits and frames during the winter, and a considerable amount of fuel if such plants must be kept in small houses or pits heated artificially. It is true, very large and lofty houses are rather difficult and costly to heat, but our common-sized vineries and Peach houses are much more easily managed as regards uniformity of artificial heat than smaller structures, and that from the greater amount of light, and the greater body of enclosed air being not so quickly heated nor so quickly cooled, and the plants thrive better. In a house with a lean-to roof—say at an angle of not more than 45°, even small plants will do far better in winter than in a rather flat-roofed pit. They will do well in a lean-to with rather a flat roof but with upright sashes in front; and they will do best of all in a span-roofed house with upright glass at the sides, provided just enough of heat can be given without making any part of the heating medium too warm.

There can be no doubt that many of us cram our glass houses far too much, and never allow a house to be empty summer nor winter. On the other hand, many who possess a nice little vinery or Peach house are so frightened to use it for anything else, that they keep it almost empty in winter, and give themselves endless trouble in keeping bedding and window plants, and even greenhouse plants, in cold pits, frames, empty rooms, &c., when all would have done so much better in the empty fruit houses during the most trying months of the year. They tell us they have too good reasons for their extra carefulness; for instance, one time their vinery was overspread with insects brought from the plants; at another time the plants themselves became too forward and weak before they could be moved; and at another time the heat given in winter caused the Vines and Peaches to break too soon and very irregularly, and thus they suffered during the season for the sake

of the plants even badly kept in winter. We can believe all this, and even much more. We know that a little over-firing and a little neglect in ventilating will bring on all these and kindred evils, even though such houses should be quite empty all the winter months. It is very easy to overdo or underdo anything, and thus the blame is often laid upon a system when the fault ought to be laid on the mode of working that system. For instance, a small fire will keep bedding plants safe in a large house; a large fire, as for Vines in February, will injure them. For those who want to make the most of their single vinery or Peach house in winter we would give the following rules:—

First, Use no plants that will not keep healthy and grow slowly in an artificial temperature of from 38° to 45°, with a rise of from 5° to 15° from sunshine.

Secondly, As a general principle do not thus fill a house until the crop is gathered, the wood ripened, the leaves fallen, and the house cleaned.

Thirdly, Do not keep such plants in a fruiting house long after you have raised the temperature for the benefit of the fruit trees—say a Peach house much above 45°, and a vinery above 50°. By, or before that time, the hardiest may be removed. Such plants as Geraniums may remain longer, if you can place them afterwards where they will experience no check.

Thus in a single vinery to which you give little heat until the buds swell and break of their own accord, you might keep your bedding plants from October to the end of March or the middle of April, and then place them under calico and mats out of doors. Camellias and Epacrises would bloom all the winter, Chinese Primulas, &c., and the Camellias would like the heat given to the Vines early in summer.

The last rule will apply to the welfare of the fruit trees, and they will not be unduly or irregularly excited into growth if the artificial heat in a Peach house be not raised above 40°, and in a vinery to more than 45°. Many plants may be kept safe and bloom at and under these temperatures, for with air early given, mere sun heat of from 10° to 15° more in a bright day will not unduly excite the trees. Whoever tries the matter carefully will find that such houses are more easily kept at a regular low healthy temperature than small pits even when heated. The very smallness renders more attention necessary, otherwise it is easy to have them freezing at one time and burning hot at another.

One great advantage of using fruiting houses for protecting purposes in the most severe months of winter is, that one can examine, pick over, surface-stir the plants, &c., in the worst or weather, when you could do nothing to plants wintered in pits. This advantage is so obvious that we advise all amateurs, when they resolve on having a pit all above or partly under the ground level, to have it wide enough to allow of a small pathway, so that all this necessary work can be done in rain, sun, or frost.

Some time ago we saw a small unheated orchard house standing empty, with good trees against the back wall, and six lights of frames outside, covered with lots of mats and litter in frosty weather. These frames, if made to take to pieces at the corners, would have stood in the little house—and what a saving there would have been in covering! whilst all the attendance and examination might have been given in the dry and comfortable house. A mat in severe weather would probably keep all secure, and more genial air could be given under such circumstances. A small iron stove in such a house would have kept all comfortable. For mild heat in small single houses nothing approaches the stove as respects economy of fuel.—R. F.

NIGHT SOIL AS MANURE.

I EMPLOYED, two years ago, as manure in my garden, night soil from an earth closet, and experienced exactly the same result from it as that complained of by Mr. Howard. The Cabbages, Cauliflowers, Carrots, Onions, Peas, and Beans treated with this manure were almost all destroyed by small white maggots at their roots. The earth as employed in the earth closets does not actually arrest or absorb the nitrogenous matter in the night soil, but only divides it very minutely; consequently when exposed to the effect of the sun and a moderate amount of moisture insect life is fostered, and the insects for their sustenance attack the roots of plants. To obviate this effect nothing is required but a more effectual means than dry earth to arrest the nitrogenous matter in the night soil. This I thought charcoal would afford. Having ready access to peat charcoal, I availed myself of it to treat the night soil with it

instead of with dry earth, and the result was all that I had anticipated. The crops were finer than I ever had them before, and no maggots, wireworms, nor slugs attacked them. I have employed night soil treated with charcoal the summer of this and of last year with perfect success, but with this difference, that the crops of the last summer, in spite of the dry season, were far more abundant than those of the preceding year.—CROMPTON.

THE STRAWBERRY ACTINIA.

The "Natural History of Redear" is an interesting little book, and certainly shows that that place abounds in every sort of marine life. It is a droll thing that our commonest Actinone (the Strawberry) is not to be found there. Mr. Ferguson mentions an attempt to acclimatise it, made by placing a couple of hundred *Fragarias* about among the rocks, but it did not seem to answer, for they all disappeared in a short time. I have noticed that this variety thrives best in rather fresher water than other kinds like, but that theory is at once knocked on the head when we look at a map and find Redear close to the mouth of a river.—KENNETH McKEAN.

[The mouth of the river is two miles away from the Sears on which the Actiniae are found.—Eds.]

PORTRAIT OF MR. RIVERS.

We have received the following testimony from a foreign admirer of Mr. Rivers:—"My gardening pursuits in fruit and orchard-house culture have always been guided by Mr. Rivers's instructions in his handbooks and periodical writings; so I have to thank him alone for success and the manifold pleasures derived from such gardening for many years. Perhaps these few lines from abroad will show that Mr. Rivers's great merits about popular fruit culture principally are appreciated not in his own country only."

The following additional subscriptions have been received:—

ENTOMOLOGICAL SOCIETY'S MEETING.

The first meeting of this Society for the present season was held at Burlington House on the 7th inst., the chair being occupied by Mr. H. W. Bates in the absence of the President. A very extensive series of donations to the Society's library from many American, continental, and English Societies of Natural History, and private donors, was announced, and thanks ordered to be given for them. Amongst these works were especially to be noticed a new general work upon the different orders of insects, beautifully illustrated by Mr. Packard, a rising American naturalist; a life of the late Thaddeus W. Harris, an American entomologist of great merit; and a memoir by Mr. Horne on the habits of a number of Indian Hymenopterous insects, illustrated with figures of their nests and transformations, with notes by Mr. F. Smith. A new part of the Society's Transactions was announced as ready for distribution.

Mr. MacLachlan exhibited a series of coloured drawings, representing the caterpillars of *Sphinx Galli* and *Ivornica* in all their states, executed by Mr. Buckler. Mr. F. Bond exhibited specimens of *Noagria brevilinea*; also a male *Caradrina cubicularis*, taken in company with a female *Senta Ulve*; also the small fly *Chlorops lineata*, found in the autumn in vast swarms on the ceilings of chambers at Cambridge, in which situation it is often elsewhere noticed, although no observation has hitherto been made as to the cause of its appearance there. Mr. Edward Saunders exhibited a gigantic Longicorn Beetle, *Xixanthrus Heros*, from the Feejee islands. Mr. F. Smith exhibited specimens of the rare *Meleoe rugosus*, found by him in some numbers at Prettlewell, near Southend, in the autumn, at the roots of grass. The males fight furiously even when at large, and two females which he had confined buried themselves in the earth of a flower pot, probably in order to deposit their eggs.

Mr. E. H. Vaughan exhibited various new or rare British Moths, including three new Phycids—*Trachonitis Pryrella*, *Homoeosoma Senecionis*, and *H. saxicola*. Mr. A. Muller exhibited some reniform gall spangles on the under side of Oak leaves, caused by *Cynips renum*, and some Pea-like galls in the same situation on Oak leaves, formed by *Cynips agana*.

The Secretary exhibited drawings and read notes on various insects—namely, *Anobium paniceum*, both larvæ and beetles, found feeding

on cayenne pepper—this insect had been confounded with *Lasioderma testaceum*, which had been found eating *Capsicum*—notes by Mr. Shoolbred on the silk cocoons of *Bombyx Peruyi*; notes and drawings by Mr. Holdsworth, of Shanghai, on various Lepidoptera and their transformations observed in China; and a note by the Rev. Mr. Warne on the black slimy larvæ of *Blennocampa Cerasi*. The following memoirs were also read:—On Butterflies from Basuto Land, by Mr. R. Trimen; conclusion of a memoir on the Longicorn Coleoptera of the Amazon Valley by Mr. Bates; on new Australian Curculionide, by Mr. Pascoe; and Notes on the Barytomine, by Mr. F. Walker.

INSECTS INJURIOUS TO THE PEAR TREE.

No. 6.

ANTHONOMUS POMORUM.

This little weevil has been named by entomologists *Curculio pomorum* and *Balaninus pomorum*. At this season of the year, and especially during frosty weather, the rough bark of Apple and Pear tree stems should be scraped off, for the purpose of destroying this insect. It shelters itself beneath the scurfy bark during the winter, awaiting the return of spring to renew its attacks upon the blossom-buds. "This insect" says Mr. Curtis, "commits great devastation in Apple and Pear orchards, by destroying the stamens, pistil, and receptacle of the flower. As soon as the blossom-buds swell the female beetle begins to deposit her eggs. In calm weather she selects a good bud, and makes a hole in it with her rostrum (long beak); she fixes herself at the hole, lays one egg, and goes on till she has deposited a considerable number of eggs in separate buds. The bud continues to swell, and the petals (flower leaves) nearly expand, when suddenly the growth ceases, and the petals wither and assume a shrivelled appearance. If one of these flower buds be examined when nearly expanded, a small white grub, with a black head, will be found in the centre, which begins to assume a yellowish colour; a few days later, the grub will be found either wholly or partially changed to a beetle—and should there be a small hole on the side of the receptacle, the beetle will have escaped; the transformation from the egg to the perfect state not having occupied more than a month. When this beetle or weevil leaves the receptacle, it feeds during the summer on the leaves of the trees, and is seldom to be seen. In the autumn the weevils leave the trees, and search for convenient hiding-places under stones about the trees or under the rough bark, in which they pass the winter. Consequently, as they commence their operations early in the spring, care should be taken to remove all stones, dead leaves, and other litter, from under the trees, as well as to scrape off the rough dead bark from them in the winter season." This beetle, or weevil, is scarcely one line and a half long; its wing-cases are dark brown, with whitish-grey stripes, its antennæ (horns or feelers) spring from the middle of its beak, and all these parts, as well as its eyes and the under part of the body, are black.

WORK FOR THE WEEK.

KITCHEN GARDEN.

WHEELING out manures, composts, earth, mud, &c., and trenching, draining, making new walks and repairing old ones, are amongst the principal operations at the present season in this department. Always make choice of suitable weather for them, with a view to cleanliness and good order. Take care to pot or lay in a sheltered situation *Cape Broccoli* and *Grange's White Broccoli*. *Celery* must be carefully earthed-up in suitable weather, and a supply of *Endive* must be blanched. *Jerusalem Artichokes* keep well and in good condition for use in the soil, and can be taken up as required; to keep the frost from injuring them, the stalks may be cut off within 5 or 6 inches of the surface of the soil and laid between the rows, or a quantity of leaves, mulching, or vegetable refuse may be wheeled amongst them to cover the surface of the ground. The best plan with *Parsnips* is to let them remain in the ground and trench them out fresh as required for use. At this season of the year, it is advisable to have wheeled on and spread over them a good coating of manure or mulching material, so that if frost set in it may always be easy to get at them. Clear away dead leaves from all growing crops, and fill up blanks as they occur.

FRUIT GARDEN.

Continue to prepare for fruit-tree planting by draining, trenching, and pulverising the soil; and after planting, stake, tie, and mulch them securely in good time. Clear away all dead leaves from the wall trees, and remove the green fruit from the Figs. The established strong-growing fruit trees that

are tardy in producing fruit should be root pruned. This operation must be performed according to circumstances; if the trees are planted too deeply, or the soil has been raised above or about them since planting, by all means fork the roots out carefully, and plant them again with care on the surface, spreading them out judiciously, and then mulching them. If trees to be operated upon are planted high and dry, fork about them at a reasonable distance, and prune back the main or strongest roots as you discover them. Very beneficial results follow from such an operation when performed judiciously. Raspberry plantations may be cleared of the dead canes and superfluous wood; the suckers should be taken off, and where required the strongest should at once be planted for succession.

FLOWER GARDEN.

Dahlias temporarily placed heels upwards under cover to dry, should now be carefully stored away for the winter. See that coarse-growing plants which may be encroaching upon their weaker neighbours are reduced, so as to occupy their proper places. Gladioli may still be planted, but most kinds of bulbs are now better in the ground than out of it. For Gladioli choose a warm, thoroughly-drained situation, work the soil well by deep digging, and add plenty of rotten manure. Elevate the bed or patch a few inches above the general level, plant the bulbs 5 or 6 inches deep and 6 inches apart, surrounding them with 1 inch of sand before covering with mould, and protect them during the winter against excessive wet and frost by means of a thick layer of sawdust, old tan, dry litter, and old carpet, thatched frames, or tarpaulin. The last three coverings must be removed during favourable weather, and the former covering entirely cleared off when the plants appear. Ranunculuses may also still be planted. The situation of the beds should be cool and somewhat moist; at the same time there should be good drainage. The most suitable soil is a hazelly loam. If, therefore, the natural soil is unsuitable, remove it to about the depth of 2 feet, and 4 feet in width, replacing it with rich loam from an old pasture; this ought to be rather firmly trodden in, and should form the foundation and principal portion of the bed. On this should be laid a liberal dressing of well-decayed manure, mixing it a little with the under soil, and over all, for the top of the bed, should be laid a layer of soil 6 inches deep for planting the tubers in; this soil should be stiffish loam, fibry, and mixed with well-decayed cow dung and leaf soil. Draw drills 6 inches apart and 2 inches deep with a small hoe, and plant the tubers 4 inches apart, with the claws downwards, gently pressing them into the soil. The crowns of the tubers should be at least 1½ inch under the surface of the bed. The beds and borders intended for Roses should be thoroughly trenched and turned, at the same time adding plenty of rotten dung, which should be well incorporated with the soil as the work goes on. This is considered to be the grand secret in Rose-growing, as without attention to this it would be vain to expect umbrageous trees or, indeed, an abundance of bloom. Of all months in the year the present is decidedly the best suited for the removal and planting of hardy summer Roses. In lifting the plants great care should be exercised to preserve as many roots as possible; avoid wrenching or straining the roots in lifting. Prune the ends of broken roots, and cut away all suckers. Deep planting is to be deprecated. Standards should be secured to stakes as soon as planted. When all this is finished fork up the surface as roughly as possible, get protecting materials in readiness, such as Spruce boughs or Furze, also dry Fern or Moss, to be applied to the most tender sorts when severe weather sets in. If possible, keep the material dry till required. To save time at another season old-established shrubs should now be gone over and pruned by shortening or removing all uncouth or straggling branches, taking care to cut in such a manner that the foliage will conceal the incision made in the branch. Proceed with the planting of evergreen and deciduous trees and shrubs. Devote any spare time or bad weather to preparing protecting material, which will be required for delicate trees and shrubs that cannot fully withstand the severity of our winters.

GREENHOUSE AND CONSERVATORY.

If the different varieties of half-hardy Lilliums are subjected to a successful mode of pot culture, they will prove most desirable objects during the summer and autumn months for the decoration of either the conservatory or greenhouse. The sorts most in repute at present for this purpose are the splendid varieties of recent introduction from Japan. The present is the best period of the season for the general potting or transplanting of Lilliums; their flower-stems are now sufficiently withered

to allow of their safe removal without injury to the bulbs, and potting thus early will enable them to thoroughly establish themselves previous to the flower-stems making a start. That they should be so established is very necessary, and of much more importance in the cultivation of this class of bulbous plants than is generally supposed. Of scarce sorts any small bulbs that may have formed on the flower-stems should be saved, and be potted separately in small pots, or planted out in a pit or frame in suitable soil, where in a year or two they will make strong flowering bulbs. If the object of the cultivator be to grow the old plants into fine large specimens, the bulbs must not be divided too much, but remove carefully as much of the old soil as can be conveniently done without disturbing the roots, and then let them be placed at once in the pots in which it is intended to flower them, which ought to be thoroughly drained, and of a deeper form than those in general use. The soil most suitable for the cultivation of Lilliums is a rich fibrous heath soil used in a rough state, and without any admixture of other soils, with the exception, should the nature of the heath soil require it, of a portion of silver sand. After potting let them be placed in a cool part of the greenhouse or in a cold pit, protecting them from severe frost only, and giving them a very limited supply of water until next season's flower-stems appear above ground, when a gradual increase will be requisite.

COLD PITS.

Cold pits afford the best possible accommodation for the culture of all greenhouse plants in summer, but unless they are furnished with pipes so that a little heat can be had to dry the atmosphere occasionally, and also to exclude frost, they are not fit quarters for many plants in winter; and although in mild winters most greenhouse plants can with care be wintered in cold pits, such as *Boronia*s, *Leschenaultias*, *Gompholobium*s, &c., if not already done, should be removed to safer quarters at once.—W. KEANE.

DOINGS OF THE LAST WEEK.

The prognostics as to the weather have been fully realised. On Sunday, the 13th, we had from 3 to 4 inches of snow, which rapidly thawed and disappeared, but almost every night we have had a sharp frost, getting more keen towards morning. These frosts from the 12th to the 19th destroyed our flower garden display. The *Colenees* succumbed three weeks ago. The *Irenee* was splendid until the 12th, or rather the 15th, for it stood the snow well. *Calceolarias* are as yet but little affected, though of course the flowering is nearly over. Some scarlet *Geranium*s elevated and rather dry in vases seem, with all the frost, to be yet sound to their points. No doubt the dry summer helped to make them more firm, and therefore less liable afterwards to suffer from the extremes of heat and cold.

Some years ago, as hints to young gardeners in managing fires, &c., we remarked that the state of the moon ought to form a part of their considerations. As a general rule the greatest cold in winter is felt just before daybreak. A brisk sharp fire in the morning will, therefore, often supersede the necessity for having large fires at night. Another secondary rule may be deduced from the state of the moon. When the moon is growing to the full the coldest temperature is generally experienced in the evening and onwards until the moon sets. At new or full moon we can scarcely calculate on much difference from sunset to sunrise, but when the moon is waning and giving its light in the early morning, it is well to provide for a fall of temperature then, especially if the sky is unclouded. During the last week, with a west and even a south-west wind prevailing up to this day, the 18th, we have had with rather mild evenings sharp frosts every morning. Most likely this will change as the moon changes. We by no means assert that such a rule is at all general: no doubt every reader could give us plenty of exceptions, but still the bulk of facts would seem to say that in a waning moon we have the lowest temperature in the morning, and that therefore a sharp fire, or a little protection before it is quite daylight, is of more importance than piling on fire or extra protection in an evening comparatively mild.

In many places it is getting customary for garden assistants to get up and take their breakfast before going out to work in the winter months. This not only makes a long period between breakfast and dinner, and puts men who live at a distance to an additional expense for fuel in the morning, but keeps them away from the garden early in the morning, when a little firing and protection would be not only most serviceable,

but most economical. A considerable amount of observation leads us to the conclusion, that men who can get a comfortable warm breakfast at 8 or 8.30 a.m., and whose comfort is otherwise cared for, will work better and wear better than other men who scarcely have a comfortable meal in summer, except the one they get in the evening; and if they have an early breakfast at home in winter, it is attended with extra early rising, and extra expense for fuel if they have everything comfortable and warm as they ought to have.

In these times it may be too true that working men may have been too selfish in studying what they thought were their own interests; but on the other hand, it is also too true that many employers do not pay so much attention to the comfort and health of their workmen as they do to the cleanliness and dryness of necessary machinery. We know of cases where, even as a matter of making the most of the hours of labour, garden men are expected to be at their work at seven in the winter and early spring months, and to have breakfasted previously. Now, work can be very well managed on this plan, but where economy in labour and in fuel are to be considerations, not to speak of the comfort of the men, we have a strong belief that from half an hour to an hour earlier at times in the morning, even though stopping for breakfast afterwards, would be the most economical mode in the end.

KITCHEN GARDEN.

The work has been to a great extent a repetition of that recorded in the previous week's notice. We pricked out more Cauliflowers, Lettuces, &c., and protected Lettuces and Endive, not covered up, for present use.

Wheeling Manure, &c.—In the frosty mornings the contents of the rubbish-heap that had been well mixed and heated, were wheeled on to empty ground; we also wheeled the remains of hotbeds into heaps, whence the material could be moved where wanted afterwards, without breaking-up walks. All wheeling on walks should be done either in frosty or dry weather. We have felt as if a blow had been given us, on noticing men pushing and striving with all their might to get a barrow along with the wheel up to the axil in mud and slush. Much depends on choosing the right time for work, if the work is to be done comfortably and economically. In particular cases such continuous work cannot be avoided, but, as a general rule, no work should be attempted which cannot be done at the time without making other work. When for short distances we are obliged to wheel in unsuitable circumstances, a great preservative from injury will be found in thinly sprinkling the place to be wheeled over with longish litter. Even under the most favourable circumstances, a similar sprinkling for some yards from the rubbish or dung heap keeps the wheel of the barrow and the feet of the wheeler clean, and thus the walks and ground wheeled over are kept comparatively unbroken. It is true they might be scraped and swept, but the less the better. Much of it is just doing work so as to make other work, a matter to be avoided when economy in resources is to be considered. A dry frosty morning is, therefore, very suitable for general wheeling; but if the frost is very sharp, and the ground hard, it is not desirable to wheel over lawns, as under such circumstances the grass under the wheel of the barrow will long retain a dark injured appearance, when the rest of the lawn looks like a fine green carpet. We have known several cases in which beautiful small lawns have thus been greatly injured in their appearance far into the summer. Nothing would take out the wheel marks. Where wheeling must be done in such cases, it would be well to use boards and planks to wheel on, and thus save the grass.
